

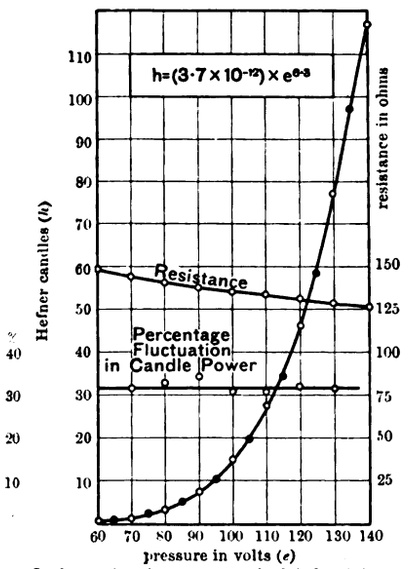

FIG. 1.—CARBON FILAMENT LAMP. 108 VOLTS.

The variation of candle-power with pressure for any glow-lamp can be expressed as follows :—

$$h = Ce^n,$$

where h is the candle-power in Hefner candles (1 Hefner candle = 0·91 British standard candle), e is the pressure in volts, C is a constant for the particular lamp considered, and n is a constant for lamps of the same type. The following values of these constants were obtained for the particular types of lamps tested :—

Carbon filament lamp	$h=(3{\cdot}7\times10^{-12})e^{6\cdot3}$
Nernst lamp	$h=(7{\cdot}1\times10^{-20})e^{10\cdot0}$
Tantalum lamp	$h=(2{\cdot}8\times10^{-8})e^{4\cdot3}$
Osmium lamp	$h=(7{\cdot}5\times10^{-6})e^{4\cdot2}$
Osram lamp	$h=(3{\cdot}4\times10^{-7})e^{4\cdot0}$
Just-Wolfram (tungsten) lamp	$h=(2{\cdot}34\times10^{-7})e^{4\cdot0}$

The curve of candle-power, as obtained experimentally for the carbon-filament lamp, conforms exactly with the curve represented by the formula above for this lamp; this is shown in Fig. 1, in which both observed and calculated points are plotted. In Fig. 2 the corresponding curve for the Osram lamp is plotted. The variation in resistance is also shown in these figures. Little interest is attached to the constant C, but the value of the exponent n is all that is needed in order to predetermine the variation of candle-power with fluctuations in pressure. If the pressure varies $p/2$ per cent. above and below the normal value e, then the total pressure fluctuation is p per cent. Now the candle-power at the higher pressure will be h_2, where

$$h_2 = C\left(e + e\frac{p/2}{100}\right)^n,$$

and the candle-power at the lower pressure will be h_1, where

$$h_1 = C\left(e - e\frac{p/2}{100}\right)^n.$$

The difference in candle-power will be, therefore, $h_2 - h_1$, where

$$h_2 - h_1 = Ce^n\left[\left(1 + \frac{p/2}{100}\right)^n - \left(1 - \frac{p/2}{100}\right)^n\right].$$

This expression can be expanded into a converging series, but the first term only of the series need be considered, as, for

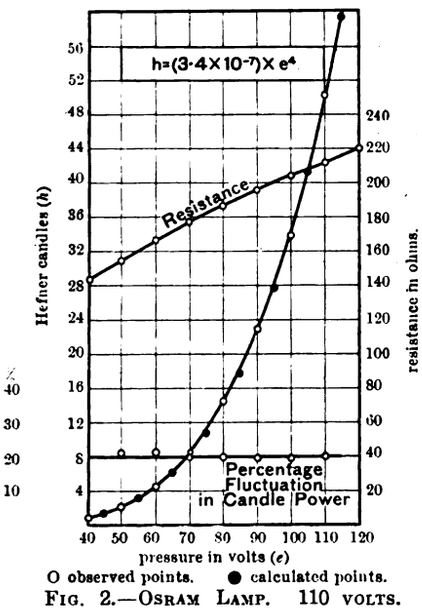

FIG. 2.—OSRAM LAMP. 110 VOLTS.

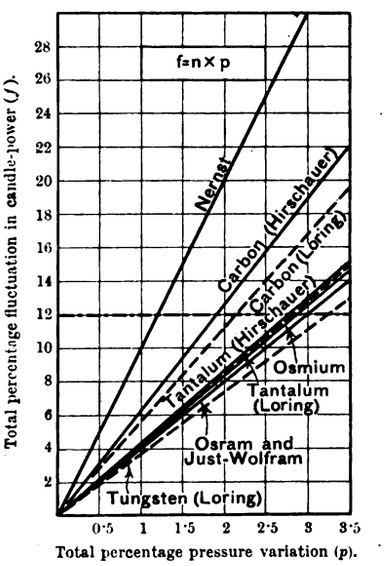

FIG. 3.—FLUCTUATION IN CANDLE-POWER WITH PRESSURE VARIATION FOR DIFFERENT TYPES OF LAMPS.

practical values of n and p, the value of the second term will be less than 0·5 per cent. of the value of the first term, thus :—

$$h_2 - h_1 = \frac{n \cdot p}{100} Ce^n.$$

It is, however, the total *percentage fluctuation* in candle-power to which the eye is sensitive; this is expressed as follows :—

$$\frac{100\,(h_2 - h_1)}{h} = 100\left(\frac{\frac{n \cdot p}{100} Ce^n}{Ce^n}\right) = n \times p.$$

Thus, the percentage fluctuation of candle-power for a given percentage variation in pressure and for a given lamp is constant and independent of the normal value of the pressure. It depends only on the value of the exponent n, and if this exponent is known, the percentage fluctuation in candle-power for a given variation in pressure can be directly determined. Applying this result to the values obtained for the exponent n, for a pressure variation of 2·5 per cent. above and below the normal value (*i.e.*, $p=5$ per cent.), we obtain the following values for the percentage fluctuation in candle-power :—

Type of lamp.	Value of the exponent n.	Total percentage fluctuation in candle-power $f = n \times p$.
Nernst lamp	10·0	50 per cent.
Carbon-filament lamp ...	6·3	31·5 per cent.
Tantalum lamp	4·3	21·5 per cent.
Osmium lamp	4·2	21 per cent.
Osram lamp	4·0	20 per cent.
Just-Wolfram lamp	4·0	20 per cent.

If a total percentage fluctuation in candle-power of only 12 per cent. is permitted, the following total percentage varia-

Digitized by Google

tions in pressure, as obtained from the curves of Fig. 3, may be allowed :—

Nernst lamp	1·2 per cent.
Carbon-filament lamp	1·9 per cent.
Tantalum lamp	2·8 per cent.
Osmium lamp	2·85 per cent.
Osram lamp	3·0 per cent.
Just-Wolfram lamp	3·0 per cent.

Thus we see that the lower total percentage fluctuation in candle-power of the metallic filament lamps is a very distinct advantage, as a much greater variation in pressure can be allowed with such lamps than can be allowed with carbon-filament lamps for a given permissible fluctuation in candle-power or brilliancy.

The article in the *Electrical World* (New York), by George Loring, contains the following results of tests similar to those made by Hirschauer, but figures for energy consumption are also given.

From the standpoint of current, candle-power, total watts and watts per candle, tantalum and tungsten lamps are less susceptible than carbon-filament lamps to changes in electrical pressures. The resistance of the metal filament increases, whereas that of the carbon usually decreases with rise in voltage.

Following are tables showing the comparative results upon carbon, tantalum, and tungsten filament lamps when they are operated at from 85 to 110 per cent. of their normal voltage.

Change of Resistance with Change of Voltage.

Percentage of voltage to that of normal.	Percentage of resistance to that of normal voltage. Carbon.	Tantalum.	Tungsten.
85	100·24	95·5	93·5
90	100·16	97	96
95	100·08	98·5	98
100 (normal)	100	100	100
105	99·91	101	102
110	99·81	102·5	104

Change of Current with Change of Voltage.

Percentage of voltage to that of normal.	Percentage of current to that of normal voltage. Carbon.	Tantalum	Tungsten.
85	85	89	91
90	90	93	93·5
95	95	97	97
100 (normal)	100	100	100
105	105	103·5	103
110	110	107	106

Variation of Candle Power Compared to Variation of Voltage.

Percentage of voltage to that of normal.	Percentage of candle power to that of normal voltage. Carbon.	Tantalum.	Tungsten.
85	41	50	55
90	56	64	67
95	75	80·5	82
100 (normal)	100	100	100
105	131	123	119
110	168	148	141

Percentage of Change in Total Watts Compared to Percentage of Change in Voltage.

Percentage of voltage to that of normal.	Percentage of total watts to that of normal voltage. Carbon.	Tantalum.	Tungsten.
85	72·5	75·5	77·5
90	81	83·5	84
95	90	92	92
100 (normal)	100	100	100
105	110·5	109	108
110	121·5	117·5	117

Watts per Candle of Lamps Operated at 85 *to* 115 *per cent. of Normal Voltage when Mean Hemispherical Candle-Power is Carbon* 3·1 *Watts per Candle, Tantalum* 2·1 *Watts per Candle, and Tungsten* 1·25 *Watts per Candle.*

Percentage of voltage to that of normal.	Watts per mean hemispherical candle power. Carbon.	Tantalum.	Tungsten.
85	5·5	3 18	1·76
90	4·5	2·73	1·57
95	3·73	2·39	1·4
100 (normal)	3·1	2·1	1·25
105	2·61	1·86	1·13
110	2·23	1·66	1·03

In glancing over the tables given it will be seen that with the exception of resistance the minimum and maximum points reached in performance when the E.M.F. changes are nearer to that of normal with metal than with carbon-filament lamps. Whereas, at 85 per cent of normal voltage a carbon lamp's resistance is 100·24 per cent. of that secured at normal voltage, that of the tantalum lamp is 95·5 per cent., and of the tungsten lamp 93·5 per cent. At 110 per cent. of normal voltage the per cent. of resistance to that at normal is 99·81 with a carbon lamp, 102·5 with a tantalum lamp, and 104 with a tungsten lamp.

On account of the different characteristics of the resistance of the carbon, tantalum and tungsten lamps the current is naturally affected in such a way that at 85 per cent. of normal voltage it is reduced 15 per cent. with carbon lamps, 11 per cent. with tantalum lamps, and 9 per cent. with tungsten lamps, and at 110 per cent. of normal voltage the current of the carbon lamp is increased to 10 per cent., of the tantalum lamp 9 per cent., and of the tungsten lamp 6 per cent.

The resistance of tungsten and tantalum lamps is less than that of carbon lamps when operated at a voltage lower than normal, and this causes their current, as has been shown, to be higher respectively, so that their candle-power must necessarily be greater. The carbon lamp gives 41 per cent., the tantalum 50 per cent., and the tungsten 55 per cent. of its rated candle-power when operated at 85 per cent. of normal voltage, and 168 per cent., 148 per cent., and 141 per cent. candle-power, respectively, when run at 110 per cent. of correct voltage. This shows that the light delivered by metal-filament lamps is much less affected than that from cellulose-filament lamps by variation of voltage. It is a matter, however, which cannot be brought out too strongly. Referring to the table showing variation of candle-power compared to variation of voltage, it is shown that a drop of 5 per cent. from normal voltage causes a reduction of 25 per cent. in the illumination received from the carbon-filament lamp, 19·5 per cent. in that received from the tantalum lamp, and only 18 per cent. in that given by the tungsten lamp. A rise of the same percentage above normal causes an addition to candle-power of 31 per cent. with carbon lamps, 23 per cent. with tantalum lamps, and 19 per cent. with tungsten lamps.

The increase in total watts is less with metal than with carbon-filament lamps operated above voltage. Burning at an electrical pressure 5 per cent. high, the energy consumed is increased 10 per cent. in a carbon lamp, 9 per cent. in a tantalum lamp, and 8 per cent. in a tungsten lamp.

The watts per candle do not vary as much with tantalum and tungsten lamps as they do with carbon when the voltage is changeable. Not only are the metal-filament illuminants far more efficient, but their percentage of change in watts per candle is much less when compared to carbon-filament lamps when run at a fluctuating voltage. Taking the specific consumption of the cellulose lamp as 3·1 watts per candle, the tantalum as 2·1 watts per candle, and the tungsten as 1·25 watts per candle at 100 volts, the respective specific consumptions would be 5·5 watts per candle, 3·8 watts per candle, and 1·76 watts per candle at 85 volts, and 2·23 watts per candle, 1·66 watts per candle, and 1·03 watts per candle at 110 volts.

When the electrical pressure is unsteady, the performance of both the metal-filament lamps mentioned herein is certainly most gratifying. The nearer the results obtained at varying voltage come to that secured at normal, the more the troubles will be diminished of the generating stations and of the persons using electricity for lighting purposes. With every recent development of a new lamp a marked improvement has taken place in this respect.

We can deduce the values of the coefficient n for the carbon, tantalum, and tungsten lamps, the results for which were given in the third table of the second of the above articles. For the carbon-filament lamp, the total percentage fluctuation in candle-power was $(131-75)=56$ per cent. for a pressure fluctuation of 10 per cent., or $n=5·6$.

For a 20 per cent. pressure fluctuation, the percentage fluctuation in candle-power was $(168-56)=112$ per cent., or, as before, $n=5·6$.

This confirms the law, deduced by Hirschauer, that the total percentage fluctuation in candle-power is equal to the product of the total percentage pressure variation and the exponent n for any percentage variation in pressure.

For the tantalum lamp the values of the exponent n are 4·25 and 4·2, and for the tungsten lamp the values are 3·7 and 3·7 for 10 per cent. and 20 per cent. total pressure fluctuation respectively.

Thus the results obtained from an analysis of Loring's table confirm the conclusion of Hirschauer for the above types of lamps, and, furthermore, the values of the exponent n obtained from the same table agree well with those values given by Hirschauer. The full-line curves in Fig. 3 are reproduced from the article by Hirschauer, but the dotted-line curves have been plotted from the results obtained by Loring. These curves show the total percentage fluctuation in candle-power (f) as a function of the percentage pressure variation (p), and the law for any one of these curves is $f=n\times p$, where n is the exponent of e in the formula for candle-power.

ELECTRIC HEATING BY ALTERNATING CURRENTS

A SPECIFICATION of some interest amongst those published last Thursday by the British Patent Office is that numbered 25,411 of 1906 by Mr. A. F. Berry, describing improvements in electrically heated apparatus suitable for cooking, boiling, ironing and other purposes. The specification is given in a slightly abridged form below:—

This invention relates to electrical heating apparatus of the induced-current type, and particularly to that kind of apparatus in which heat is produced in a plate, support, oven wall or partition, heating screen or other like body (hereinafter referred to for brevity as a hot plate) by the action of alternating current flowing through the external current-carrying portion of a secondary circuit, the other or internal portion of which (hereinafter called for distinction the secondary element) is wound upon a magnetic core and has a secondary current induced in it by the action of a primary alternating current of higher voltage passing from a source of electric supply, such as ordinary supply mains, through a primary conductor wound upon the same core and hereinafter called for distinction the primary element. In apparatus of this kind, where the hot plate forms part of the secondary circuit, and this circuit forms a single turn of metal, so that the current flowing therethrough is of very great strength and low voltage, a considerable amount of heat is liable to be transmitted by conduction from the hot plate to the secondary element, and thence to the primary element through the connecting portion of the secondary circuit that is between the hot plate and secondary element, and which is necessarily of large section, whereby the resistance of the primary element is increased, and heat is also radiated from and so lost through the said connecting portion of the

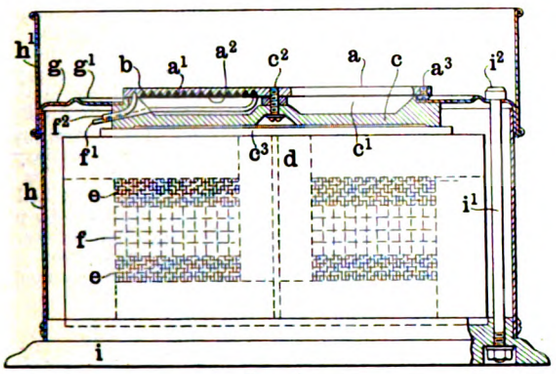

FIG. 1.

circuit, with the result that the efficiency of the apparatus is reduced, and the hot plate may also be less uniformly heated than is desirable.

Now an object of the present invention is to improve the efficiency of apparatus of the kind referred to, and to increase the uniformity of heating over the whole surface of the hot plate by modifying the external current-carrying portion of the secondary circuit, so that it can be made of reduced cross-sectional dimensions, thus minimising its heat-conducting and radiating powers, and, consequently, the heat loss referred to. Further objects of the invention are to improve the relative arrangement of the conductors forming the primary and secondary elements, so as to improve the power-factor of the apparatus, and also to so generally improve the construction of the apparatus as to render the same very durable in use. To this end, according to the present invention, a part of the current-carrying portion of the secondary circuit (hereinafter called for distinction the supplementary secondary element) connected in series with the secondary element of the apparatus is composed of a conductor which may be wound, coiled, or otherwise arranged in one or more layers in the closest possible proximity to, but insulated from, a plate, or a number of rings, of conducting metal arranged to constitute a tertiary circuit in which currents are induced by the alternating current traversing the supplementary secondary element, which thus becomes a primary element thereto, the said conductor being disposed so that the whole of the said plate, or the rings, becomes or become uniformly heated, or practically so. The cross-sectional dimension of the conductor is such as to lessen the tendency for heat to be conducted from the tertiary circuit through the supplementary secondary element to the connecting portions of the conductor, and thence through the secondary element to the primary element on the magnetic core whilst the apparatus is in use, and at the same time to permit the employment of comparatively large secondary currents at low voltage, say for example of the order of between five and ten volts, and still larger currents in the tertiary circuit. By casting the conducting metal constituting the tertiary circuit or hot plate of the desired shape, and with the metal suitably distributed, and so as to come into the closest possible proximity to the supplementary secondary element, the said tertiary circuit or hot plate will be heated both by current induced in it by the supplementary secondary element, and also by heat conducted to it from the supplementary secondary element, which may be covered in so as to protect it from the cooling and oxidising action of the external air, and to stiffen it mechanically.

The apparatus, which thus comprises primary and secondary elements on a magnetic core, and a heating portion consisting

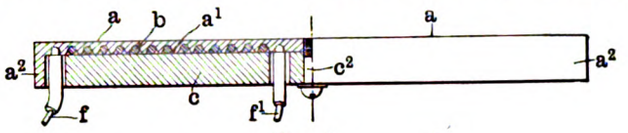

FIG. 2.

of a supplementary secondary element and a tertiary circuit or hot plate, may be constructed in various forms.

In the accompanying illustrative drawings, Fig. 1 is a central vertical section, with parts removed, showing one construction of apparatus embodying the present invention, and suitable for heating kettles, saucepans, and other vessels. The supplementary secondary element with the hot plate constitutes the tertiary circuit, with which it is combined. Figs. 2, 3, and 4 are part sectional elevations illustrating modified forms of the supplementary secondary element and hot plate in central vertical section and plan, another construction of hot plate with supplementary secondary element. Fig. 5 shows a construction of apparatus embodying the present invention suitable for use as a laundry iron, being a sectional elevation.

In the example shown in Fig. 1, the hot plate *a* consists of a thin, circular plate or disc, *a*, of conducting metal, as, for instance, muntz metal, but preferably of metal, for example, iron or steel, on the underside of which is located the supplementary secondary element *b*. This element consists of a spirally wound inductive coil or conductor comprising several convolutions, arranged in the same plane, and formed of wire of ordinary circular section, as shown in Fig. 1, or of strip material arranged with the sides of the metal strip at right angles to the plane of the disc *a*. The conductor forming the supplementary secondary element *b* may be wound or coiled outwards from the centre of the plate or disc *a*, or conversely from the centre towards the outer edge thereof.

For the purpose of maintaining the conductor of the supplementary secondary element *b* in proper relative position to the tertiary circuit, and for obtaining the maximum conversion of electrical energy therein into useful heat energy, the plate or disc *a* of the latter circuit may advantageously be formed on its underside, as shown in Fig. 1, as by casting or turning, with a spiral groove, a^1, corresponding more or less to the section or part section of the conductor *b* forming the supplementary secondary element, and into which groove the conductor can be wound and secured. A convenient manner of effecting this is to first insulate the conductor *b* with a covering of suitable material capable of withstanding heat, for example, with berrited asbestos, composed of a thin layer of asbestos paper saturated with the insulating material known

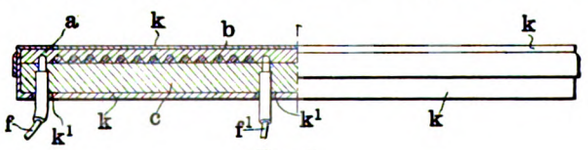

FIG. 3.

in commerce as "berrite," and then wind the same into the said grooves in a lathe with the aid of a guide plate comprising a number of spring sectors. Or it may be insulated subsequently to its being wound in place, as, for instance, by enamelling or coating it with a suitable composition; for the latter purpose the groove a^1 in the plate *a* in which the conductor is to be wound may be coated with some appropriate vitreous enamel or the like, and after it has hardened, the bare conductor is placed in position therein, and the remainder of the groove filled with the material constituting the enamel, and the whole raised to the requisite temperature to cause the conductor to be embedded in and secured in position by the enamel. Or the conductor may be embedded in the material constituting the enamel whilst the same is in a powdered condition, and within the groove, the said material being afterward fused by heat to securely fix the conductor in place and insulate it from the plate *a*.

Digitized by Google

A protective plate, a^2, of sheet metal, for example, iron, steel, or the like, is then secured, as by screws a^3, to the lower side of the plate a, so as to hold the supplementary secondary element b firmly in place, and protect it from the cooling and oxidising action of the external atmosphere. The supplementary secondary element b thus constituted may be supported by an asbestos or asbestos-covered carrier, c. In the example shown in Fig. 1, the carrier c is shown as composed of a recessed block of insulating material, above which is directly located the plate a^2, the space c^1 between the said carrier c and plate a^2 being filled with material, for example, mica dust, that is a bad conductor of heat. The block c is secured to the hot plate a by a set screw, c^2, and the whole is firmly held upon the iron core d carrying the primary and secondary elements e and f by a stamped flanged metal ring, g, that is adapted to fit firmly over the outer portion of the block c, and tightly over the top of a casting, h, enclosing the said

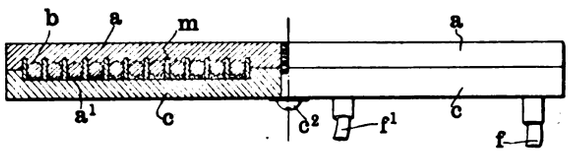

FIG. 4.

core with primary and secondary windings, the whole being secured tightly together and to a wooden or other base, i, by bolts, i^1. A ring, c^3, of asbestos or like badly-conducting material may be placed between the block c and core d, and the heads of the bolts i^1 are insulated from the ring g by washers i^2 of insulating material. The hot plate a extends a short distance above the ring g, which, when stamped to the shape shown, to impart strength thereto, has the annular recess g^1 therein filled with insulating material, for example, the material commercially known as uacolite, to form a smooth flat surface. The portions f^1, f^2 of the secondary conductor connecting the secondary element f to the supplementary secondary element b are led through the recess in the block c, and are preferably insulated as shown. e^1 is a switch for controlling the circuit of the primary winding e. h^1 is a draught excluder of thin sheet metal, arranged to closely fit the stamped ring or lid g. The plate a^1, instead of being made of sheet metal, may be made of thicker metal, say, of the thickness of the hot plate, a, so as to form a duplicate tertiary circuit, the two plates wholly embracing or surrounding the said supplementary secondary element b, so as to further enhance the efficiency of the apparatus.

In Fig. 2 the insulated supplementary secondary element b rests directly against the asbestos block or carrier c, and against the underside of the hot plate a, which is flanged at

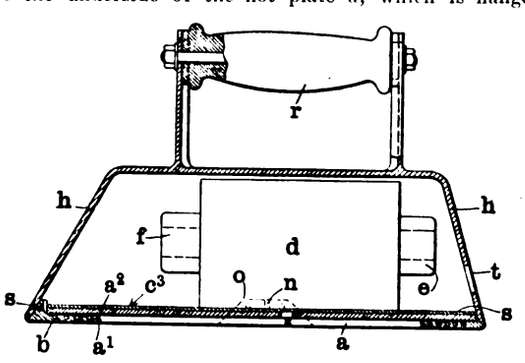

FIG. 5.

a^2 so as to embrace and confine the wound conductor and the block or carrier c in place. In Fig. 3 a hot plate, a, is shown, in which the conductor b is wound as above, and a carrier, c, of asbestos, fireclay, or the like then placed in position next to the conductor, and the whole confined within a divided metal casing, k, that may be polished or nickel-plated at the top, and the separate parts of which are brazed or soldered together whilst under pressure. The apertures k^1, through which are passed the leads f, f^1 that connect the supplementary secondary element b to the secondary element e in the case h (Fig. 1), may be left free to serve as blow-holes until after the apparatus has been tested, when they may be sealed in any suitable manner, such as by enamel. In the same way, a duplicate tertiary circuit may be provided and secured in place in lieu of the carrier c. As an alternative to the modes above alluded to, for constituting the spiral groove a^1, a spirally wound partition of strip brass may be employed, incorporated in a mould so that the top or tertiary circuit can be cast thereon. A hot plate thus produced is shown in section in Fig. 4, wherein m are the portions of the brass strip forming the partitions, a the hot plate cast thereon, and b the wire or conductor forming the supplementary secondary element. Or the wire b forming the supplementary secondary element may be threaded through brass or other metal tubing, which may be placed in or against the hot plate, or coiled to form a hot plate, as will be understood without illustration. The supplementary secondary element may comprise more than one layer of spirally-wound conductor, and in some cases the tertiary circuit, instead of being formed as a solid plate, may be perforated. Another figure (not reproduced here) showed a hot plate embodying both of these features, the secondary element comprising two layers of spirally-wound conductor. Also, for some purposes, as for a heat radiating screen or plate, the tertiary element may be formed of a series of metal rings, or rectangular or other shaped frames of different sizes spaced apart one inside the other, and connected together by connecting bars. The hot plate, instead of being a non-magnetic metal such as muntz metal or brass, or of unlaminated magnetic metal, such as iron or steel, surrounding, or partly surrounding, the supplementary secondary element as hereinbefore described, may be made partly of non-magnetic and partly of magnetic metal, as shown, for example, in Fig. 4 hereinbefore referred to, where the top portion of the plate a is of iron, and the lower portion, formed by the spiral partition, m, of brass.

In the further example of apparatus embodying the present invention shown in Fig. 5, the hot plate a is arranged to form the bottom or sole of a laundry iron, and is made of any usual shape in outline, its upper surface being formed with a continuous groove, a^1, for the reception of the insulated conductor forming the supplementary secondary element b, which is held in place by the protective metal plate a^2. To the upper side of the plate a^2 is secured a layer, c^3, of insulating material, such as asbestos or uacolite, upon which the core d carrying the primary and secondary elements e and f is secured, it may be by a winding of wire n passed around lugs o on the top of the hot plate a. The core with windings is enclosed in a casing h, for example, of cast aluminium, which is provided with ventilating holes q, and provided with a handle, r, the said casing being secured to the hot plate, as by screws s. t is a hole in the casing h for the reception of a nipple for attachment of a flexible cable to the primary winding of the apparatus. The primary and secondary elements e and f with magnetic core d may be common to a number of supplementary secondary elements with hot plates, as in the case of cooking apparatus designed for use as a boiler, griller, oven, and so forth, and of laundry irons, switches being provided for controlling the connection between the several supplementary secondary elements b thereof, and the main secondary element f. The main secondary element f in apparatus constructed as described may consist of several turns, and is or may with advantage be placed between two portions of the primary element e, or between two primary elements, so as to increase the power-factor of the apparatus. The details of construction can be variously modified.

The claims are as follows:—

1. Electrical heating apparatus of the induced-current type as herein set forth, wherein the current-carrying portion of the secondary circuit includes an element which is supplementary to the main secondary element upon a magnetic core, and acts as a primary element to a tertiary circuit forming the heating device proper, so that current flowing in the aforesaid supplementary secondary element will uniformly heat the tertiary circuit by induction as well as by conduction, substantially as set forth.

2. In electrical heating apparatus, according to the preceding claim, a hot plate of electricity and heat-conducting material, the under or upper surface whereof is subject to the uniform inductive effect and heat radiation of an insulated element wound and located in the closest possible proximity to the lower or upper surface thereof, substantially as set forth.

3. In electrical heating apparatus, according to the preceding claims, a hot plate in which the inductive winding or conductor is confined within a groove or grooves in the hot plate, fashioned in any of the ways hereinbefore described.

4. Electrical heating apparatus, according to the preceding claims wherein the conductor forming the element for heating the hot plate is wound within a spiral or other groove or recess formed in the hot plate, and is held in such groove or recess by a plate or cover that serves primarily to protect it from the action of the external air, substantially as described.

5. Apparatus, according to Claim 1, comprising primary and secondary elements on a magnetic core, and a heating portion comprising a supplementary secondary element in circuit with the first-mentioned secondary element and a tertiary circuit or hot plate, the whole combined to form a single heating block or device, substantially as described.

6. For electric heating apparatus, according to Claim 1, a combined hot plate and inductive winding in close contact therewith, constructed substantially as hereinbefore described with reference to certain of the accompanying drawings.

7. Electrical heating apparatus of the kind herein referred to having its several parts constructed, arranged, and adapted for use substantially in the manner hereinbefore described with reference to certain of the accompanying drawings.

AN ITALIAN WATER-POWER STATION

THE large water-power generating station at Trezzo is one of the most important installations of its class in Italy, and embodies some distinctive features, especially as regards the arrangement of the hydraulic

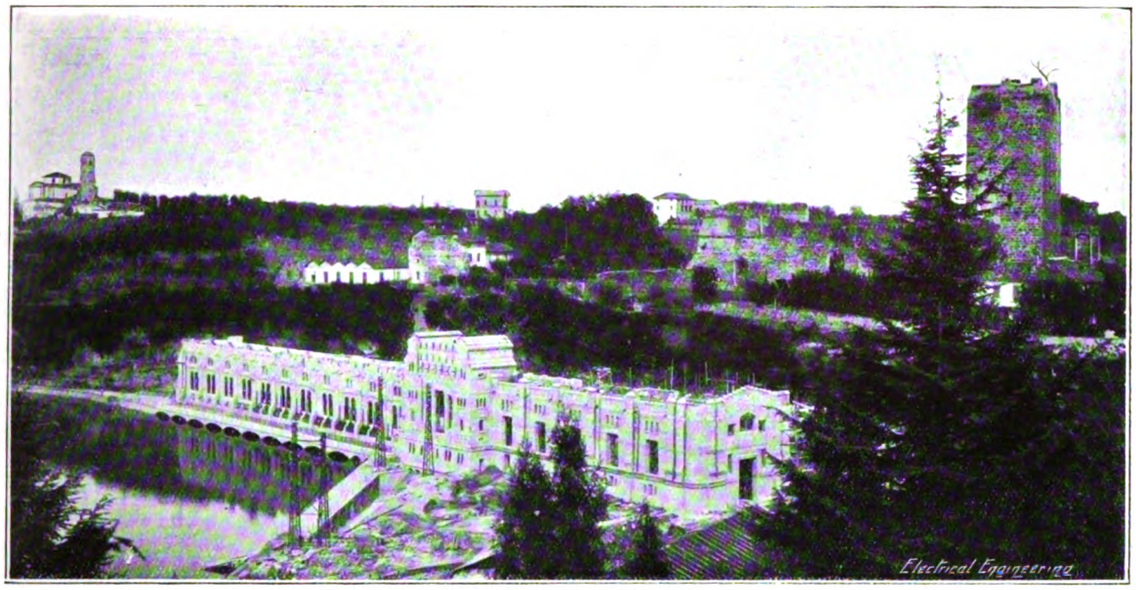

Fig. 1.—General View of Power-House.

portion of the equipment and the greater amount of attention paid than is often done to the architectural features of the power-house. The station building, which is shown in Fig. 1, is situated close to the old castle of Trezzo, on a narrow peninsular of land, round which flows in a sinuous course the river Adda.

In contradistinction to many water-power undertakings, there are no separate intake works, nor any intake canal nor pipe line, as the power-house is on the river bank itself, a short distance above the dam. The water, after having passed through the low fall turbines, is taken through a pair of tunnels about 100 metres in length, and discharges on the other side of the peninsular into the river. A fall of 6 to 8 metres is available. The dam, which it is unnecessary to describe in detail, lies obliquely across the river on the side of the peninsular where the power-house is situated, just above the sharp bend of the river, and a canal, 12 metres wide, with a lock, connects the upper and lower portion of the river for purposes of navigation. Just behind the power-house a discharge basin running its whole length has been excavated, of

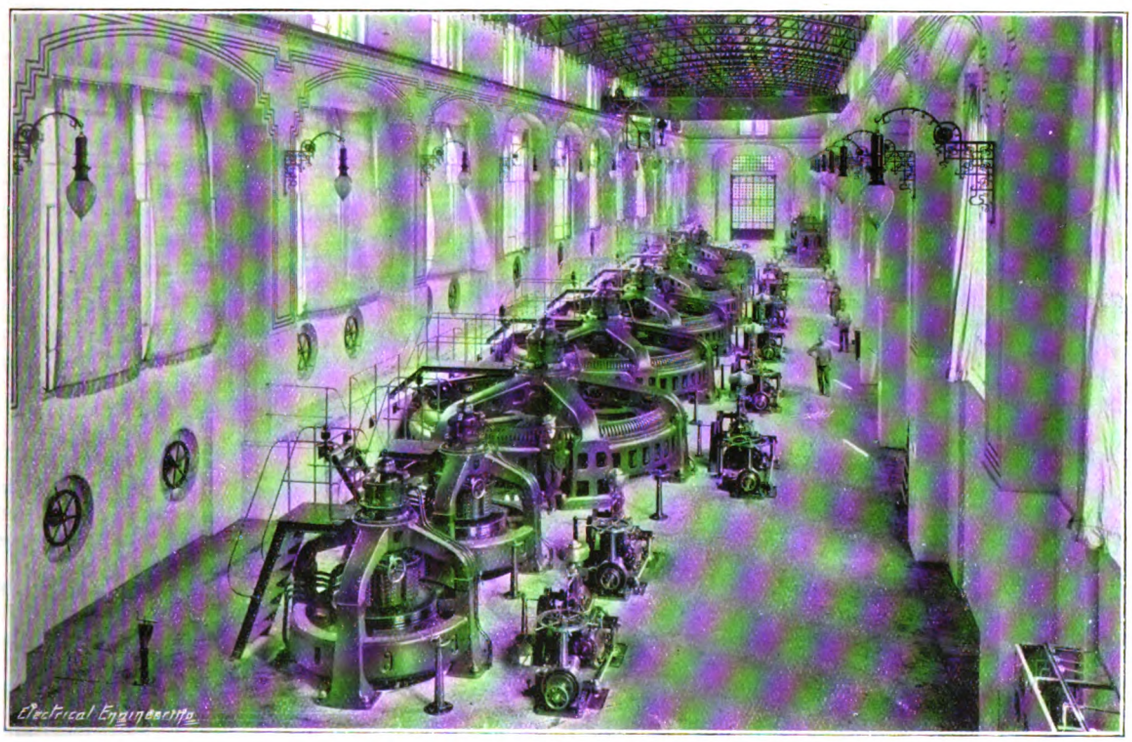

Fig. 2.—View of Part of Interior of Power-House from Switchboard Gallery.

Digitized by Google

a width varying from 15 to 22 metres, in which the height of the water ranges from 2·5 to 5·5 metres. The discharge tunnels from the basin are 90 metres in length and 10 metres in diameter, and are 30 metres apart from centre to centre.

The initial equipment at the station comprises nine main 1,000 kw. generating sets, and the necessary separately driven exciters. When complete the station

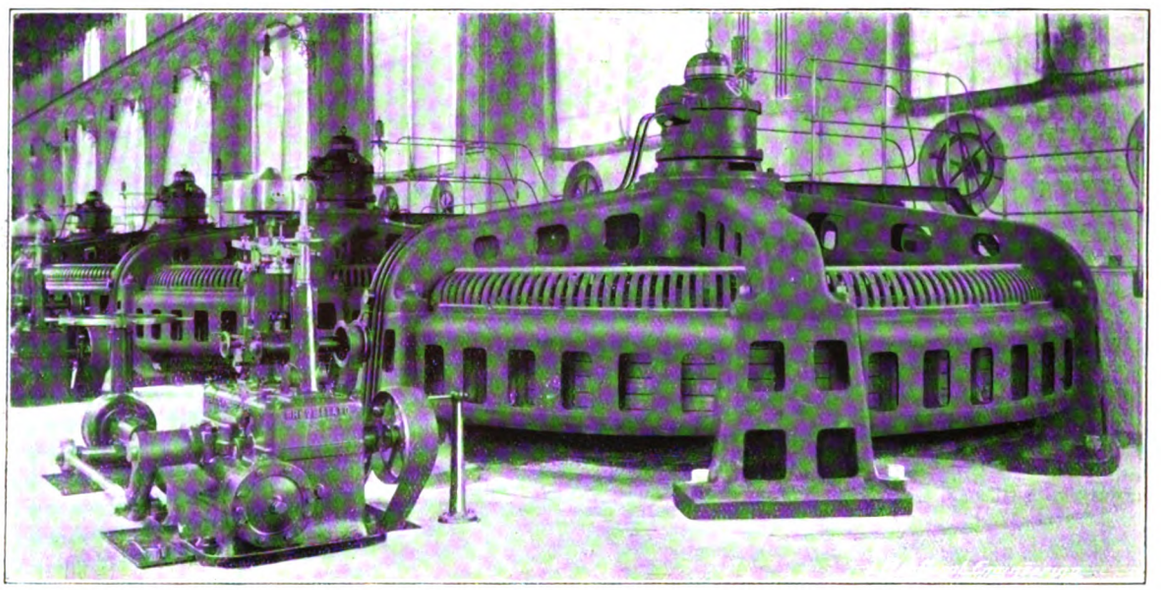

FIG. 3.—1,000 KW. VERTICAL SHAFT ALTERNATORS.

will contain twelve generators, of which ten will be for the supply of alternating current at 42 cycles, while the remaining two will be for a frequency of 50 cycles. These latter are intended for the supply of current to the Società Bergamasca d'Elettricità, and those of the lower frequency for the distributing network of the Hydraulic Power Co. of Trezzo. The water consumption of the large turbines is given as

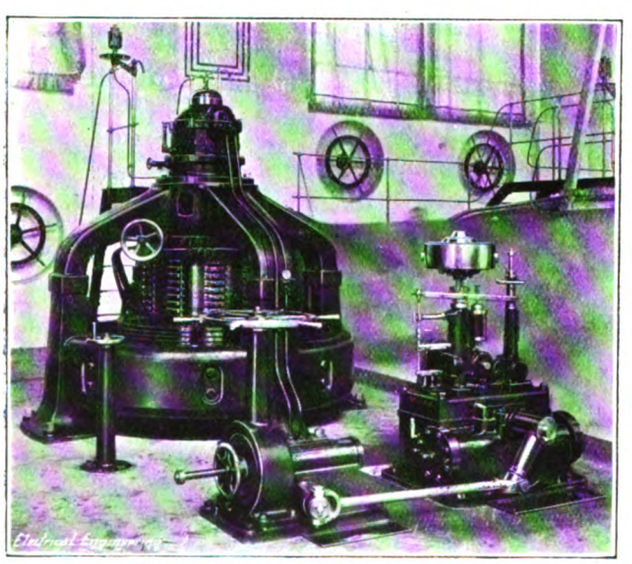

FIG. 4.—TURBINE DRIVEN EXCITER.

16,000 to 17,000 litres per second, and that of the exciter turbines as 3,000 to 4,000 litres per second. They run at speeds of 105 and 190 r.p.m. respectively, and are designed to develop their full load with a head of water varying from 6 to 8 metres. Each unit consists of two water-wheels, mounted one above the other on the same vertical shaft, a practice often made use of to facilitate obtaining a sufficiently high speed when only a low head of water is available. One of these wheels takes in water from below, and the other from above, so that they both discharge into a single channel between them. The lower wheel is subjected to the total head, and its reaction serves to take a part of the weight of the revolving system. The upper wheel, on the contrary, has the pressure of the water between its runner and the top of its case lightened by means of a syphon tube in communication with the discharge channel. Appropriate guides in the space between the wheels direct the water into the right direction.

The rotors of the alternators are coupled rigidly to the turbine shafts, and are supported from bearings at the top. A view of part of the interior of the machine room is seen in Fig. 2, and Fig. 3 gives a more detailed representation of the alternators. The appearance of the line of generators is undoubtedly imposing, and the general effect is distinctly enhanced by the simple but effective scheme of interior decoration of the building. The alternators were supplied by the Unione Elettrotecnica Italiana, and are of the internal revolving field type, with a stator diameter of 6 metres. The stator of each machine is constructed in two parts, and is carried on six feet mounted on reinforced concrete foundations. There are two bearings; that at the top, as already remarked, is a thrust bearing, while the lower one serves simply as a guide bearing. The total weight of the revolving mass is about 24 tons. The stator core is constructed with open slots. The 42-cycle alternators are wound for 13,800 volts, and the 50-cycle machines generate at 7,000 volts. The windings consist of former-wound coils retained in the slots by wooden wedges, and have all been required to withstand an insulation test of 20,000 volts between the conductors and earth.

The laminated poles of the revolving field are mounted on the heavy cast-iron body of the rotor, and carry windings of bare copper strip insulated with paper. The total moment of inertia of the revolving parts is given as 250,000 kgm². The upper bearing has a ball thrust, and runs in oil. It acts also as a guide bearing by means of a white metal bush, and is water cooled. The lower bearing, close to which are mounted the slip rings for the exciting current, is provided with a similar bush. Both bearings are lubricated from a lubricator mounted above, and the oil passes first through the upper bearing and then through a channel in the shaft to the lower bearing.

Digitized by Google

There are two exciter sets driven by separate 240 h.p. turbines. One of these is shown in Fig. 4. They have eight poles, and are rated at 1,250 amperes at 130 volts at 190 r.p.m. The general arrangement of the bearings and their lubrication is similar to that of the large sets. The commutators are above the armatures for ease of access.

In addition to the hydraulic machinery described above, a supplementary steam plant is provided in the right-hand wing of the building, as seen in Fig. 1, consisting of four 1,000 kw. sets, driven by horizontal steam engines, and supplied by a battery of six boilers. The object of this plant is to make up in winter for the insufficiency of the flow of the river Adda. The switchboard gallery is placed in a raised position between the hydraulic and steam machine rooms, so that a good view of both can be obtained. The switchgear is naturally divided into two sections for the 42-cycle and 50-cycle plant respectively. It follows the usual cellular type of construction, in which the various bus bars, instrument transformers, high tension switches, &c., are separated from one another by cement partitions. The current from the 42-cycle generators passes through the machine oil switches and instrument transformers to a machine bus bar in the form of a ring, which can be sectionalised so as to cut out any one machine panel that may be required. The water and steam-driven 42-cycle machines are all connected up to this board, which has provision for 14 sets, including future extensions. From this ring machine bar connections are taken from two diametrically opposite points to what may be termed the distributing bus bars. By this means the distributing bars, which, however, are not laid out in the form of a ring, can be fed from either end, and here, again, provision is made to isolate any panel. A further coupling bar is provided, by which the two sets of feeding connections can be coupled together if required. It will be seen that this arrangement is very flexible, but it involves the use of a very considerable number of sectionalising switches. The control boards are of the "desk" type, with flush type instruments mounted in the inclined panels and the switch and rheostat handles in front.

Amongst the outgoing overhead lines radiating from the station one is for the transmission of energy to the electricity company of Monza, and terminates at a transforming station belonging to the Conti Co. Another line is carried in the direction of Gorgonzola, and branches out into three portions, leading respectively to Crema, Pioltello, and Crescenzo. An unusual feature of the system is the employment on certain short branch sections of the transmission lines of iron wires for the transmission. The branches in question are taken from the main 13,800 volt. They are only a few kilometres in length, and are only for the transmission of loads of less than 100 kw. Under these conditions the somewhat greater inductive drop due to the use of iron is not sufficient to be of consequence, and an appreciable economy in the cost of installation is obtained. Another distributing company supplied from the Trezzo station is the Società della Martesana, which was established solely for this purpose.

Electric Testing Stations in London.—The Highways Committee of the L.C.C. have received as a deputation the subcommittee appointed by the conference which was convened last year by the Hackney Borough Council to consider the arrangement of joint action before the Board of Trade relative to the intention of the L.C.C. to prescribe fees in respect of duties performed by their inspectors in visiting testing stations established in the County of London by electric light undertakers under the provisions of special Acts or Orders. The sub-committee was appointed to take all necessary steps to oppose the establishment of testing stations, principally on the ground of the large and unnecessary expense which would have to be incurred.

A NEW SURFACE-CONTACT SYSTEM

A NEW surface-contact system, for which considerable advantages are claimed, is being developed by Mr. D. Suchostawer, of Vienna, and an English syndicate is being formed in connection with the system. No actual line has as yet been equipped, but experiments have been conducted with a working model embodying the leading features. Full details of the working of the system are not available for publication at the present time, but we understand that the principal directions in which advantages are claimed are as follows:—

The danger of a "live" stud is reduced to a minimum by the use of a gravity pull-off, and by a complete leakage trap. The studs are of small area, and project very slightly above the paving, and the switching movement is very simple. The depth required for the stud or pick-up boxes and the line wire is but a few inches below the street surface, so that no special excavation is needed to accommodate them, the excavation for the tramway structure sufficing. The cost of the studs is low, every part being adapted to manufacture by simple machine tools on the interchangeable principle. The cost per mile of single line is said to compare favourably with that of a well-built overhead system, but for a double line it may be somewhat higher. The magnetising current needed for the pick-up is very small, owing to the employment of a good effective magnetic circuit in both stud and car magnet. The cost of maintenance may be expected to be low, because of the simple character of the movement, the substantial design of the parts, and the ease of examination and replacement thereof.

The system, which has been favourably reported on by Mr. H. M. Sayers, is claimed to be suitable for the third rail for railway work, as well as for street tramways.

Faraday House.—The annual dinner of the Faraday House Old Students' Association, which had been fixed for the 21st inst., has been indefinitely postponed in consequence of the death of the wife of the President-elect.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the Institution on Thursday:—*As Member:* Dr. E. Rosenberg, c/o British Westinghouse E. & M. Co., Ltd., Trafford Park, Manchester. *As Associate Members:* W. B. Bayliss, H. M. Boydell, L. G. Clark, J. E. Elliott, H. N. Fullarton, H. M. Fulton, E. W. Heather, S. M. Hopewell, A. H. L. Lucas, J. M. McGown, C. R. Whipple. *As Students:* H. Autton-Carter, H. A. Bailey, G. F. Barbour, B. G. Bellamy, D. Betts, J. R. Boyer, R. V. C. Brook, W. Brown, J. Cunliffe, A. R. Dunton, W. G. Edwards, A. Gardner, S. Ghosh, R. D. Gifford, A. Y. Jarrett, L. M. Jockel, J. H. C. Kann, V. Kilvert, N. Martin, A. Mizzi, B. F. Mulholland, S. G. Nottage, H. J. K. Osborn, H. L. O. Parish, C. A. Pilson, F. H. Pullum, A. W. Puttick, J. P. Quinn, N. S. Sim, L. Solomon, H. A. J. Stanton, M. Swift, F. E. Windross, M. W. Wood.

Wireless Telegraphy in the Navy.—According to the *Naval and Military Record* a considerable increase is being made in the staff of wireless telegraph operators in the Navy. At present there are, it is believed, about three hundred efficient wireless operators in the fleet, and another hundred are about to be placed under instruction. The course for these men on board ship after their preliminary instruction lasts sixty days. They begin by sending and receiving groups of letters and words, and have the instruments and their uses explained to them. After ten days they go on with twenty days of simple exercises in sending and receiving short messages on two days a week, the training class in one ship talking by "wireless" to the training class on board another ship in the same fleet. Cypher messages are also interchanged. Then for another twenty days they go into a more advanced lot of messages, and are taught how to get their instruments rapidly into adjustment, and how to maintain and repair them. They also start to read Poldhu messages, and to increase the pace of both sending and receiving until they are finally examined for their general fitness. A smart wireless telegraphist should be able to signal at the rate of about twenty-five words per minute after such a course, and this meets the needs of the fleet at present. A rearrangement of the telegraphist and signal ratings has been made in order to avoid the demand for wireless operators depleting the ordinary signal branch of the service.

SOME NEW MOTOR SWITCH-GEAR

THE accompanying illustrations represent some special switchboards for the control of motors, which have recently been supplied by the Adams Manufacturing Co., of Bedford. In Fig. 1 a special board for the control of two large motors is shown.

It will be seen that for each motor a double-pole switch is provided, together with two single-pole porcelain handle fuses, an ammeter, and a motor-starting and speed-regulating switch. This latter is fitted with automatic no-volt and overload release, and is of the double-lever type, which permits of the motor being started, and its speed varied over a wide range, by means of shunt regulation with the use of only one handle. This method secures an absolutely perfect interlock between the starter and the field regulator, and effectually prevents the possibility of attempting to start the motor while any resistance is in series with the field coils.

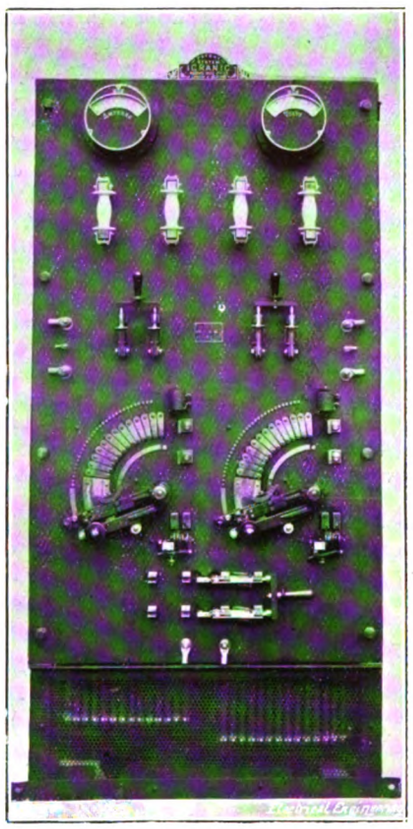

FIG. 1.—CONTROL PANEL FOR TWO MOTORS.

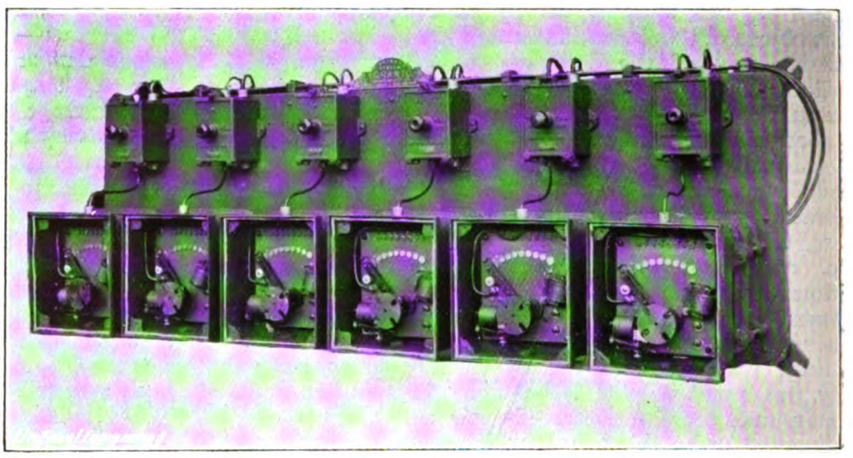

FIG. 2.—SPECIAL ENCLOSED MOTOR SWITCHES, WITH COVERS REMOVED.

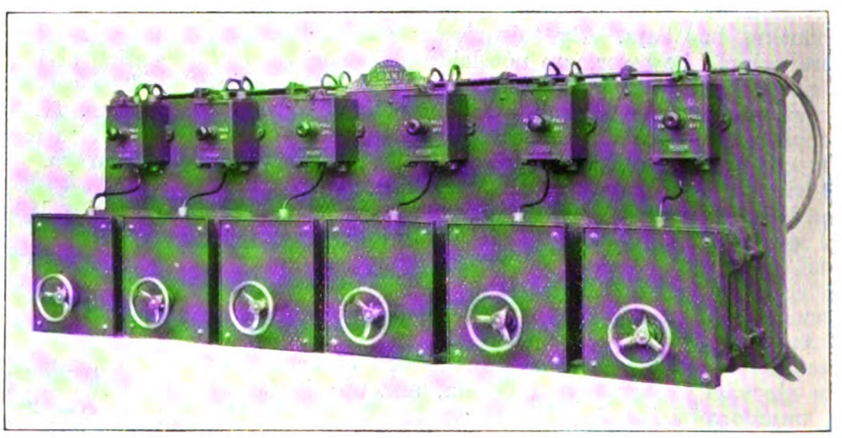

FIG. 3.—ENCLOSED MOTOR SWITCHES, WITH COVERS IN PLACE.

At the bottom of the panel is a double-pole change-over switch, whereby the load may be changed over from one motor to the other at will. The starting and regulating resistance is contained in a strong ventilated iron box, which serves also as a support for the panel. Figs. 2 and 3 show a group of six ironclad speed-regulating resistances of a new type, which the company have introduced to obviate the difficulties which are presented when series speed-regulating switches are required to be used in positions where it is necessary that they should be absolutely waterproof. In this apparatus the resistance is entirely enclosed in a cast-iron casing, fitted with gills, in order to increase the radiating surface. The resistance, therefore, does not depend at all upon a current of air through it to carry off the heat. As a matter of fact, the air never comes into contact with the resistance material at all, but only with the outer surface of the cast-iron case. As a consequence, this type of resistance may be installed not only in positions which are damp, but might be used even in positions where the resistance is liable to occasional immersion in water, or to have the water dashed over it, and this makes it peculiarly suitable for colliery work, and for breweries, and for mineral water manufacturers, as well as for use on shipboard.

The board illustrated has recently been supplied for use in the bottling stores of a large brewery, where water is even more plentiful than in other parts of a brewery. It will be observed that the switch is contained in one cast-iron box, which is provided with glands through which the connections can be made, while the resistance is mounted behind the switch-box, and consists of gilled cast-iron plates of the type described above.

Proposed Subways in Vienna.—According to the *Railway Gazette*, the Austro-Hungarian Ministry of Commerce is considering the construction of an underground electric railway for linking together the district post offices of Vienna, of which there are between 60 and 70. The proposal is for a tunnel 25 ft. below the surface, with a height of 5 ft. and a breadth of 4 ft. 6 in., the stations being situated, of course, under the post offices. A motor van and three cars, each of the same capacity as an ordinary post van, will form the train, which it is proposed to run at about 20 miles an hour.

Railway Electrification in Brazil.—According to an American Consular Report, the increase in suburban railway traffic of Rio de Janeiro has been so great as to call for some solution of the problem of providing adequate facilities for the large population which depends for transportation upon these trains. The number of passengers carried in the suburban trains increased from 12,600,000 in 1901 to 19,250,000 in 1906, an increase of about 52 per cent. It has been proposed that the suburban lines be electrified and plans are now being made to that end. The mileage will probably be about 20 miles, and the present estimate places the cost of the work at about $3,500,000, but it is thought probable that it cannot be done for less than $5,000,000. Three years is to be the time limit for the completion of the work. The plan specifies that trains are to run on a schedule providing a three-minute service, or 20 trains per hour, accommodating 40,000,000 passengers per year.

THE LOSSES IN POLE SHOES DUE TO ARMATURE TEETH

A PAPER by Messrs. T. F. Wall and S. P. Smith, which was read and discussed last week at the Newcastle Local Section of the Institute of Electrical Engineers, described the results of some experiments made to determine the loss in dynamo-electric machines due to the pulsations of the flux set up in the pole shoe by the movement of the armature teeth across the pole face. The way in which these losses arise can be seen from Fig. 1, which shows the distribution of the flux in the air-gap when the machine is running light. From this figure it is at once obvious that the flux density at any point on the pole face will vary according to the position of the armature teeth relative to that point; consequently, as the teeth move across the pole face, the flux in the shoe will pulsate. The magnitude of these pulsations depends chiefly on the value of the mean flux density over the whole pole

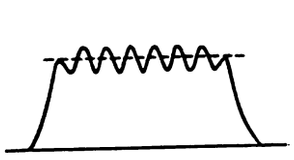

FIG. 1.—FLUX DISTRIBUTION ON NO-LOAD.

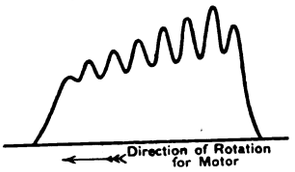

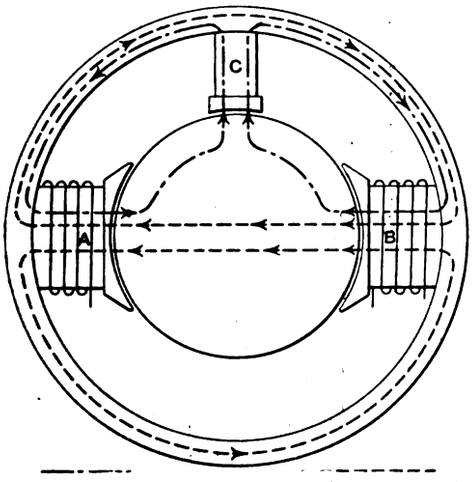

FIG. 2.—FLUX DISTRIBUTION ON LOAD.

surface, and on the relation between the slot-opening and the air-gap. The E.M.F.'s set up by the flux pulsations produce corresponding eddy currents, and these, in turn, tend to damp out the fluctuations. The damping action is mainly dependent on the frequency of the pulsations, the thickness of the laminations (if any), and the nature and temperature of the iron. Further, the presence of a current in the armature has a large influence on these losses, as may be gathered from Fig. 2, which illustrates the distorting effect of the armature current on the field and its corresponding effect on the magnitude of the flux pulsations.

Under the assumption that the flux pulsates according to a sine law, the calculation of these losses has been carried out by Potier and Rüdenberg. The flux pulsations are probably not sinusoidal, however,* and have, consequently, a larger form factor than a sine curve, whence it is to be expected that the theoretical formula given by these investigators would give results less than those obtained by experiment. It will be presently seen that this is actually the case.

The experiments made by the authors are based on the assumption that the whole of the energy loss, caused by the pulsating flux, is dissipated as heat, and the method consists in measuring the heat thus dissipated. This was done by determining the amount of energy—supplied from an external

Flux distribution when A and B have like polarity.

Flux distribution when A and B have unlike polarity.

FIG. 3.—DIAGRAM OF EXPERIMENTAL MACHINE.

and measurable source—that must be expended in order to obtain the same conditions of heating as when the actual losses are present In other words, the heating due to eddy currents is imitated by artificial heating. It was of the highest importance, therefore, to make certain that all other forms of heating were identical in the two cases. This was done as follows:—

The experimental machine was a 5-h.p. dynamo with commutating poles, and had four main poles. Two of the main poles, which were diametrically opposite, were used for the production of the flux, the other two along with all the commutating poles being removed. The experimental pole shoe was specially designed for these experiments. This was made of massive wrought iron, and so arranged that the gap could be varied at will. The experimental pole is denoted by C in Fig. 3, whilst A and B represent the main poles. Suppose now that A and B are excited in such a way that A becomes a N pole and B a S pole. The flux will then pass directly from A to B, and the *experimental pole* C *will be free from flux*, provided the magnet system is symmetrical with regard to it. Under these conditions, therefore, no eddy currents will be induced in the experimental pole shoe. Suppose now that the current in one of the exciting coils be reversed, the poles A and B will then have the same polarity, and the pole C will now form a return path for the flux issuing from A and B; further, whilst A and B have large pole shoes in comparison with C, it is at once obvious that the flux density in the experimental pole shoe may be made to assume high values.

In both the above cases, however, the heating due to the exciting current in A and B is precisely the same, provided the current is kept constant throughout. It will thus be seen that when A and B have unlike polarity, the heat in the pole shoe C is solely due to the heating of the machine; whilst when A and B have like polarity, the heating of the pole shoe C will be due to exactly the same causes as before, together with the additional heating caused by the eddies and hysteresis produced by the flux pulsations in the shoe. Hence it may

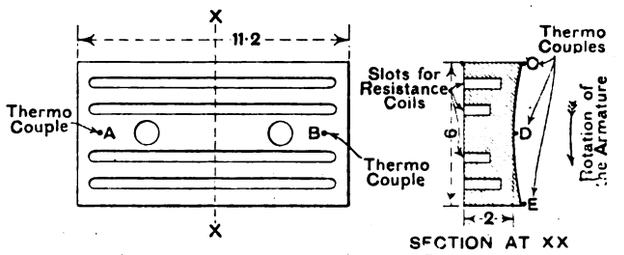

FIG. 4.—THE EXPERIMENTAL POLE SHOE. (DIMENSIONS IN CM.)

justly be concluded that the difference of temperature of the pole shoe in the two cases is due to, and is therefore a measure of, the losses caused by the pulsations of the flux in the shoe. The experiment, therefore, resolves itself into finding out to what dissipation of energy this temperature-difference corresponds. This was done as follows. In the experimental pole shoe, Fig. 4, slots were cut, and in these slots resistance coils were laid. Each slot contained two coils, which could be connected non-inductively in series or parallel, as desired. Further, since the plane of the coils was perpendicular to the pole face, any possible flux, due to the current in the resistance (or heating) coils, which may have been present, was in the worst possible direction for producing any effect which might vitiate the results when it was desired to heat the shoe artificially. When the main poles were of opposite polarity, and consequently no flux went through the experimental pole, current was sent through these coils, and, by suitably adjusting this current, it was possible to make the temperature of the shoe the same as that produced by the eddy currents when the main poles had the same polarity and the flux went through the experimental pole. When this equality of temperature was reached, the power supplied to the heating coils was measured, and this power was then taken as equal to the loss of energy produced by the flux pulsations—an assumption which the authors now proceed to justify.

From the drawing in Fig. 4, it will be seen that the resistance coils are completely embedded in the pole shoe, so that all the heat developed by these coils must be absorbed by the pole shoe, to be afterwards dissipated from its surface. To prevent as much as possible a transfer of heat, the pole shoe was insulated from its core by a sheet of mica. The temperature of the pole shoe was measured by means of thermo-couples, balanced on a potentiometer. There were five thermo-couples in all, which were made by simply soldering copper wires on the shoe, whilst an iron wire soldered to the shoe served as a common terminal to all the couples. In this way it was possible to explore the temperature-distribution over the whole

* G. W. Worrall and T. F. Wall, *Journal Institution of Electrical Engineers*, vol. 37, 1907, p. 148.

Digitized by Google

shoe, both when it was heated by the losses and when it was heated artificially. This was important, since the validity of the equivalence of the artificial heating to the heating by the eddy losses depends chiefly on the distribution of the temperature being the same in the two cases.

The order of each experiment was as follows. The machine was allowed to warm up with flux (and therefore eddy currents) in the experimental pole shoe, then, after attaining a steady temperature, the E.M.F.'s of the thermo-couples were balanced. After this, the current in one of the exciting coils was reversed and at the same time artificial heating was applied by means of the resistance coils; then, after one to two hours, the temperature would have again become steady, and the thermo-couples could be balanced. This had to be repeated, by varying the heating current in the resistance coils, until sufficient points were obtained for drawing a curve containing the point corresponding to the potentiometer readings with flux in the pole shoe.

The first series of experiments was made to find the law connecting the eddy losses in the pole shoe with the flux density. The results are shown plotted in Fig. 5. The losses in each

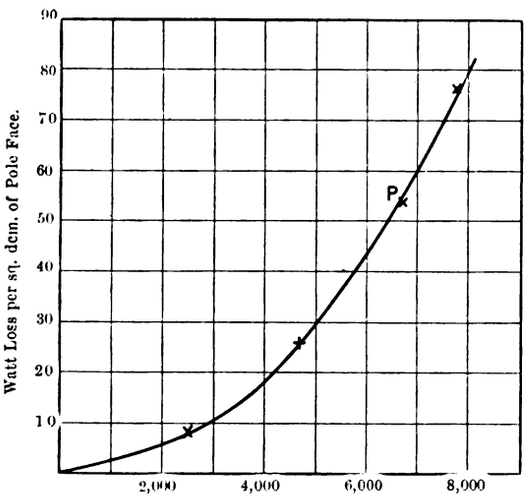

FIG. 5.—CURVE SHOWING RELATION BETWEEN LOSSES IN POLE SHOE AND FLUX DENSITY IN AIR-GAP.

Experiments A { Air-gap constant $\delta = 1{\cdot}9$ mm. Speed constant $n = 580$. Armature current = 0.

case have been reduced to the "losses per square decimetre of pole shoe face," and are given in watts (area of pole shoe face $= 1{\cdot}12 \times 0{\cdot}6 = 0{\cdot}67$ dcm.^{2}).

The equation for the curve is—

$$W_B = kB_l^{2\cdot1} \text{ watts per sq. dcm.}$$

where k is a constant.

If these losses are calculated from Potier and Rüdenberg's theoretical formula, they will be found to be considerably lower than the above. The following is an example of the method for determining a point, P, on the curve of Fig. 5. After four hours' running with a flux density in the gap of 6,700, readings were taken for the five thermo couples, and the average value was 26·9. The connections were then changed, and the shoe warmed by the resistance coils, and readings were taken at intervals of 1½ hours of the potentiometer and of the watts supplied. A curve was then plotted with the mean values of the potentiometer readings for the five thermo-couples as abscissæ, and the corresponding watts consumed in the resistance coils as ordinates. Thus a curve is obtained for the heating of the pole shoe, which now serves as the calibration curve for the particular experiment in question. Taking, then, the mean value 26·9 of the potentiometer readings after the four-hour runs with eddy losses, the corresponding watts from this curve are 36·5. Reducing this to the loss per square decimetre of pole face, we get for point P, when the flux density is 6,700 :—

$$\text{Eddy current loss} = \frac{36{\cdot}5}{6 \times 11{\cdot}2} \times 100 = 54{\cdot}3 \text{ watts per dcm.}^2$$

This point P is then plotted on the curve showing the relation between the losses and the flux density (see Fig. 5).

The second series of experiments was devoted to finding the relation between the pulsation losses in the pole shoe and the speed of the armature.

The several points were obtained in the same way as the points in the previous series of experiments, except that in the present case the only variable was the speed.

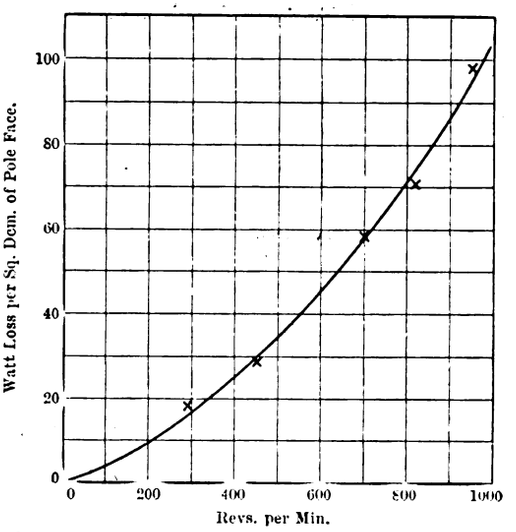

FIG. 6.—CURVE SHOWING RELATION BETWEEN LOSSES IN POLE SHOE AND SPEED OF ARMATURE.

Experiments B { Air-gap constant $\delta = 1{\cdot}9$ mm. Flux density constant $B_l = 5{,}800$. Armature current = 0.

The results of these experiments are shown by the curve of Fig. 6. The equation of this curve is—

$$W_n = k\left(\frac{Z\,n}{60}\right)^{1\cdot5} \text{ watts per dcm.}^2,$$

where Z = number of armature teeth = 53, n = speed in revs. per min., and k is a constant.

The object of the third series of experiments was to find the effect of the ratio of the length of the air-gap to the slot-opening on the eddy current losses in the pole shoes. To keep the flux constant whilst the gap was varied the following device was used. The exciting current in the field coils was kept constant throughout, and the gap was varied by inserting pieces of cardboard between the pole shoe and the pole core. By this means both the magneto-motive force and the reluctance of the

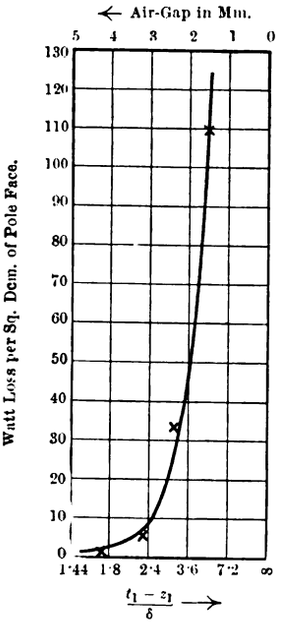

FIG. 7.—CURVE SHOWING RELATION BETWEEN LOSSES IN POLE SHOE AND RATIO SLOT-OPENING TO AIR-GAP.

Experiments C { Speed constant $n = 900$. Flux density constant $B_l = 6{,}000$. Armature current = 0.

magnetic circuit (neglecting any alteration in the leakage coefficient brought about by the above change) were kept constant, consequently the flux must remain constant. That this was actually the case was confirmed by the ballistic galvanometer.

Digitized by Google

The gap was thus varied from about 6 mm. to a mean value of 1·5 mm., but it was found that the losses were imperceptible when the gap was greater than about 4 mm.

It is not of much interest, however, to know how the losses vary with the length of the air-gap without at the same time knowing the relation to the opening of the slot and the width of the tooth; for upon this relation the losses depend, as was stated before. The curve in Fig. 7 is plotted from the results of these experiments. The equation of this curve is—

$$W_\delta = k\left(\frac{t_1 - z_1}{\delta}\right)^{3\cdot5} \text{ watts per dcm.}^2;$$

where—

t_1 = tooth-pitch at armature circumference, z_1 = tooth-width at armature circumference, $t_1 - z_1$ = slot-opening at armature circumference, δ = mean length of air-gap (measured in same units at t_1 and z_1), and k = a constant.

An idea of the magnitude of the heating may be gained from the fact that, with the smallest gap (1·5 mm.), it became impossible to hold the hand on the experimental pole shoe after the machine had been running a few minutes.

All the previous experiments were carried out when the machine was running without current in the armature. It is also of importance, however, to know what effect the load has on the eddy losses set up in the pole shoes by the fluctuations in the field caused by the teeth.

The current was sent through the armature as follows: When running without flux in the experimental pole, the machine was driven by a motor, and current was simply passed through the armature from an external source. The armature being wave-wound, with the brushes at 90° (geometrical) apart, no E.M.F., of course, was induced between the brushes due to the rotation of the armature in the field, so that the armature winding acted simply as an ohmic resistance. When running with flux in the experimental pole shoe, the machine ran as a motor, and was loaded until the same current flowed in the armature, as in the previous case. The exciting current was maintained constant throughout.

The curve of Fig. 8, which is plotted from the results obtained from the fourth and last series of experiments, shows how the eddy losses in the pole shoe increase as the load increases, which is what we should have predicted on account of the distortion of the field.

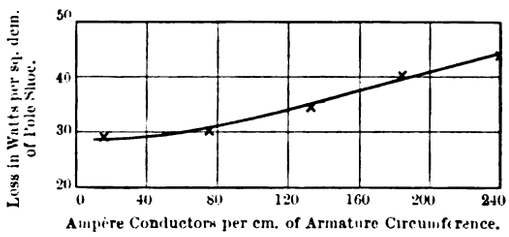

FIG 8.—CURVE SHOWING RELATION BETWEEN LOSSES IN POLE SHOE AND LOAD CURRENT.

Experiments D. { Air-gap constant $\delta = 1·9$ mm. Flux density constant $B_l = 4,700$. Speed constant $n = 600$.

The readings given by the thermo-couples in this series of experiments showed clearly the distortion of the field under the pole shoe by the fact that one of the pole tips (C) becomes much hotter than the other (E).

CONCLUSIONS.

Summarising the results given by the above experiments, the following equation is obtained for the losses in pole shoes due to eddy currents induced by the pulsations in the field set up by the armature teeth:—

$$W_p = k\left(\frac{t_1 - z_1}{\delta}\right)^{3\cdot5} B_l^{2\cdot1}\left(\frac{Z\,n}{60}\right)^{1\cdot5} 10^{-11} \text{ watts per sq. dcm. of pole face;}$$

where k is a constant depending on the iron, &c., and is equal to 0·046 in the present case.

Far more can be learnt from the curves directly, however, than from such an equation, which can be nothing further than a comparison. Moreover, it is much better to know how to avoid these losses than how to calculate them, and to this end the above curves form a comparatively safe guide. Undoubtedly, the most important of them all is the curve showing the relation between the losses and the ratio of the slot-opening to the length of the air-gap (Fig. 7). This curve—which was taken for a fairly high flux density in the gap (6,000) and a moderately high speed (900)—shows that, provided the ratio slot-opening to air-gap does not exceed 1·5, the losses in the shoe are practically zero. Even when this ratio is as high as 1·8, the eddy losses are only some 3 watts, and probably the designer's practical rule of keeping this ratio below 2 can be accepted as about right. At any rate, this may safely be taken as the limit at which it is necessary to discard solid pole shoes in favour of laminated. In other words, unless the gap is very small, or the flux density is very great, or the speed is very high, the use of laminated shoes is not necessary—for the small increase thereby gained in efficiency does not compensate for the increased cost of construction.

Finally, the authors take this opportunity of expressing their appreciation of the valuable advice and assistance which Dr. E. Arnold has at all times so readily given, and the facilities for research work placed at their disposal in the laboratories in the Electrotechnic Institute, Karlsruhe.

DISCUSSION AT NEWCASTLE.

Dr. W. M. THORNTON (Armstrong College, Newcastle) emphasised the remark in connection with Potier and Rudenberg's formula that the flux pulsations are probably not sinusoidal, by pointing out that the effects of hysteresis would make the wave-form far from a sine curve. It would be a "spiky" wave form. He asked whether the presence of the slots for resistance coils in the experimental pole shoe would not disturb the heat-flow, and whether the thickness of the shoe would not have some effect in this connection. The results in Fig. 5 were expressed in terms of watts loss per square decimetre of pole face; to convert into English units, watts per square foot, it was necessary to multiply by 9·3. A figure of half a kilowatt per square foot of pole surface was thus easily obtained—a most important loss in practice. Referring to Fig 8, the extended importance of this loss on a loaded machine was seen: presumably the pole-face loss was increased 50 per cent. at full load. It was curious to notice that heating occurred most strongly under the pole-tip, where the field is strongest. Previous to these experimental results it might have been argued that, as magnetic disturbance giving rise to eddy currents would occur with most freedom on the lower parts of the saturation curve, the heating would be most felt at the weakest portion of the field, but this view was upset by the experiments. He would think that the constant k in the author's last formula was almost entirely dependent on the conductivity of the pole-face iron. The statement concerning the relative cost of laminated and solid pole shoes might be challenged, as there was a widespread idea that laminated pole shoes were cheaper, not dearer, than solid. He would ask if any experiments were made on the influence of the shape of the pole shoe, and the number of teeth under the shoe. There was also the influence of the shape of the pole tips and the effect of ventilation of the spaces between the poles to be noticed.

Mr. C. TURNBULL (Tynemouth) wished for information about the humming of dynamos. Mr. Wall came from Stafford, and the Stafford firm had solved the question of humming exceedingly well. With reference to the question of the cheapness of laminated poles, it would be noticed in Fig. 7 that when the ratio of slot-opening to air-gap exceeded, say, 1·8, the watts lost in the pole shoe increased alarmingly. Now, some firms are keen on making the ratio considerably over 1·5, in order to keep their slots as open as possible, cutting down lost space due to winding-insulation, and also cost of cutting the teeth. They make up for this by laminating the pole faces, and this method is, to them, cheaper.

Mr. F. O. HUNT wished to know how the thermo-couples were actually arranged on the pole. He also wished to know whether any experiments were made to check the effect of the relative curvature of the pole-face and armature-face as the air-gaps were varied. He pointed out that the question of the relative cost of machines with laminated or solid pole shoes was complicated with considerations as to whether the pole pieces were to be laminated as well, in which case Dr. Thornton was, he believed, of the opinion that the eddies due to the influence of the armature teeth were not surface effects only, but that the tufting of lines proceeded to a considerable depth below the face, and that there was, therefore, an eddying or "boiling" effect under the surface. Dr. Thornton's own recent experiments would support this view.

Mr. NYBORG mentioned in connection with pole laminations that Messrs. Lahmeyer had laminated their poles to a depth equal to from 45 to 75 per cent. of the slot pitch.

Mr. CLAGUE raised the question as to whether it was correct to take the substitutional heat of resistances, *i.e.*, heat applied internally, as a fair measure of heat required from an external source by the metal of the pole face in the course of ordinary operation.

Mr. T. CARTER (communicated) thought that the authors were perfectly correct in saying that the most important set of experiments is that summed up in the curve given in Fig. 7. Their conclusion that the ratio of slot-opening to air-gap should be less than 2, if pole shoes are not to be laminated, seems almost to preclude the use of solid pole shoes altogether, at any rate in the smaller sizes of a range of machines. For to get the ratio less than 2, either the slot opening must be small or the air-gap

Digitized by Google

large. The former means generally a large number of slots, involving great expense in notching, and a large amount of waste space in slot insulation; and the latter involves extra field copper. Mr. Carter, from his own experience, thought that the tendency is to arrive at values of the ratio increasingly in excess of 2, and so to make absolutely necessary the use of laminated pole shoes, or completely laminated poles. Mr. Carter stated that figures could be produced showing that laminated poles were actually cheaper than solid poles and pole shoes, as regards material and labour (given correct methods of manufacture). It must also be remembered that solid cast poles are very uneven in their surface, and very much more clearance between them and the field coils is required than in cases where laminated poles with accurately flat surfaces are used, so that the latter tend also to some saving in copper, other things being equal.

Mr. WALL, in reply, said that if Dr. Thornton's idea that the depth of the pulsations extended far below the iron surface was correct; then, of course, the method described fell to the ground, as no attempt at measurement could be made. The cost of laminated pole shoes appears to merge into a question of the whole of the design. As to humming, no definite experiments were made on this point by the authors, but he remembered that when the air-gap was exceedingly small the humming was excessive. This points to the fact that humming depends on the ratio of slot to air-gap. The actual arrangement of the thermo couples was as follows:—Holes were drilled at the exact centre, and the two lateral edges of the under face of the pole shoe and copper wire sweated in, a similar arrangement being followed for the upper face. The iron wire forming the common member of the six couples was fixed to one outer corner of the shoe.

A NEW CONDUIT JOINT

ONE of the chief difficulties in the design of a satisfactory conduit system has always been the provision for ensuring electrical continuity throughout the installation, and a great deal of ingenuity has been expended from time to time in devising methods which combine adequate protection in this respect with lower installation cost than can be obtained by the use of screwed conduit tubes. An inherent weakness in some of these inventions has often been that too much reliance has been placed for electrical continuity upon a close mechanical contact between two even surfaces, which was liable to be upset by

inequalities in diameter of the different fittings and such irregularities.

A new system has been brought forward by the Armorduct Manufacturing Co., under the patents of Mr. H. C. Pearson, with the object of providing reliable electrical continuity with a cost of installation not much exceeding that with ordinary socket-joint material. The accompanying illustrations show some applications of the system, which is designated as the "Witton Grip." A conduit fitting of the ordinary non-screwed type, and of the size ordinarily used, is slotted to part of its diameter, and a claw grip metal band, which is fitted with sharp projections or teeth, so as to engage the tube firmly when the binding screw is tightened home. In the closing and scraping movement which naturally results, the enamel, which would otherwise prevent electrical continuity, is automatically removed. A mechanical contact of great strength is secured, and electrical continuity is ensured.

Arrangements are being made by the company to adapt all standard conduit fittings to this principle, and at present all the ordinary fittings are available for the same.

Some tests of sample fittings have been made by the Electrical Standardising, Testing, and Training Institution, of Faraday House. In one case, five short lengths of enamelled steel tubing were connected together by two "T" pieces and two elbows, these being fitted with "Witton Grips," the total length of connected tube being 6 ft. 9 in., and its external diameter $\frac{5}{8}$ in. The resistance of this tubing, including the eight joints, was found to be as low as 0·0409 ohm, with a current of 12 amperes passing. To test the mechanical strength a 12 in. length of the same size tube was fitted with an inspection box at each end. One box was fastened and a tensile stress of 130 lb. was applied to the tube. The grip showed no signs of giving way. A further test was made on this sample to try the effect of torsion upon the joint. One box was gripped in a vice and the other twisted. It was possible to turn the latter through an angle of 270° before any slip took place in the grip.

ELECTROCHEMISTRY AND ELECTRO-METALLURGY

LAST March (Vol. I., p. 563) we published an article upon "Extensions of the British Aluminium Co." In it we referred to the large power scheme in course of construction in Inverness-shire and Argyllshire. A portion of this scheme was set in operation on Christmas Day (this Vol. p. 25), and we have now information that the Norwegian scheme at Stangfjord has also started operations. Including the old works at Loch Foyers the company have now three plants in operation for the manufacture of aluminium. They are therefore in a position to very largely increase their output. At the present price of aluminium, and even taking into account the low price of copper, for electrical purposes for equal carrying power aluminium is claimed to show a considerable saving as against copper. In electrical installations we may therefore look forward to a considerably increased employment of aluminium, and there is little doubt that the metal will be more and more largely used for manufacturing articles in which lightness of construction is of importance.

In the *English Patent* 13,696 (June 13th, 1907), a method for soldering aluminium and alloys containing aluminium is described. The surfaces of the aluminium or its alloys are first thoroughly cleaned, after which they are coated with ammonium stearate. In order to prepare this flux, stearic acid is melted, and then 30 to 40 parts of aqueous ammonia are slowly stirred into it. The surfaces to be joined, having first been covered with the stearate, are coated separately with a solder, which consists of 10 per cent. copper and 90 per cent. tin. After this the two surfaces can be soldered together either with this solder or with an ordinary solder. It appears not to be necessary for the proportions of the tin and copper in the solder to be exactly as described above.

The American production of aluminium in 1906 was 6,406 tons, valued at £1,076,250, and in 1907 it was 8,964 tons, valued at £2,393,750. Artificial graphite, which is another product of the electric furnace, was manufactured to the quantity of 2,173 tons, the value being £65,159; the production for 1907 showed a large increase, being 3,092 tons, and the value was £100,774. The total amount of copper produced in the United States in the year 1906 was 409,652 tons, valued at £37,625,070. In 1907 the production was slightly less, being 399,600 tons, but owing to the high price of copper the total value was rather greater, being £38,578,632. About 87 per cent. of the copper produced in the United States is electrolytically refined.

According to the *United States Patent* 869,114 (October 22nd, 1907), boron carbide can be produced by mixing a compound of boron, such as boron oxide, with carbon in excess, and heating it to the temperature of reaction in an electric resistance furnace. The escaping gases produce a pressure within the furnace, and this appears to help the formation of the carbide, which has a composition of B_6C. It has a metal-like fracture, and the specific gravity is about 2·7. If the temperature is not kept constant, various forms of the carbide can be produced. By slowly cooling the product contraction takes place, and caverns open up within the mass; in these large crystals may be obtained.

The ordinary etching of plates for printing is done by the action of ferric chloride and gelatine impregnated with chromic acid. There are, however, difficulties in employing the method, for example, with bronze, copper or zinc, bubbles of gas are given off, and these raise the chrome-gelatine so that sharp etchings are not obtained. It is now found that (*English*

Digitized by Google

Patent 28.319. November 12th, 1907) the chrome-gelatine acts as a diaphragm. Consequently, by making the metal to be etched the anode in a bath of any acid electrolyte, the metal becomes etched, the diaphragm showing a different permeability to the electrolyte according to whether it has a long exposure to light or not. The current employed should not be of too low a density, and should vary from 0·35 amp. per square centimetre to 2 amperes. It is also stated that the E.M.F. of the bath should not be too low, which it would hardly be with a current density of the magnitude of 2 amperes per square centimetre.

ELECTRICAL SCIENCE

British and American

Demagnetisation of Iron.—An elaborate investigation of the principal points of interest arising in connection with the method of "demagnetisation by reversals" for the purposes of magnetic testing, is described very fully in the January *Bulletin* of the Washington Bureau of Standards. The author, C. W. Burrows, used in nearly all his experiments two parallel specimens about 50 cm. long, with their adjacent ends joined by wrought-iron yokes. The magnetising coils were two long coils of 400 turns. The secondary coil was uniformly wound over the middle part of one specimen. Transformer iron, common iron, low-carbon steel, and high-carbon steel were all experimented with. The author's first endeavour is to find a satisfactory criterion of perfect demagnetisation. With this in view, the following experiment was carried out:—A specimen was demagnetised as thoroughly as possible, and then submitted for a moment to a known magnetising force, which gave it a known residual induction. Then the "apparent" induction of the substance in this state was measured; that is, the throw of a ballistic galvanometer was observed on reversing suddenly a definite small field applied merely for the purpose of the test. These operations were repeated with increasing magnetising forces, and the author demonstrates that the existence of residual magnetism in a specimen diminishes the apparent induction; and thus establishes the proposition that the criterion of perfect demagnetisation is that the induction shall be a maximum. The author now proceeds to the study of what he calls the "polarisation effect." This is the difference between the induction throw given by a completely demagnetised specimen and that given by a specimen possessing residual magnetism, the testing field reversal being the same in both tests. The polarisation effect is thus in some degree a measure of the incompleteness of any previous demagnetisating process imposed upon the specimen. In the first set of experiments the neutral iron was submitted to a field of 100 gausses, and this field was applied and removed several times without reversal. After this the apparent induction was measured, various measuring fields being used on various occasions. The conclusions are that the polarisation effect is always positive, that it increases to a maximum and diminishes to zero as the magnetising force used for measurement increases, and that the point at which the polarisation effect vanishes is rather higher than the point of maximum permeability. This critical point is shown to be an important point of the magnetic diagram by another series of experiments, in which the original strong magnetising field is given in turn different values. The author next turns his attention to the wide-spread assumption that a necessary condition for perfect demagnetisation by the method of reversals is that the demagnetising current must carry the iron from an induction greater than any previous one it has experienced down to a vanishingly small one. His experimental process consists in demagnetising a strongly, definitely magnetised specimen by a series of reversals, whose initial amplitude is taken lower and lower in different experiments, the final amplitude being always extremely small. The apparent induction was measured after each demagnetising series at that field value which was known by previous experiments to give the maximum polarisation effects. The author found, for all the materials he used, that there is a critical force for the amplitude of the initial demagnetising reversal. There is no advantage, in respect of perfection of demagnetisation, in carrying the reversal fields higher than this critical demagnetising force, whatever value the original high magnetising force may have had. The author finds a very similar theorem for demagnetising reversals that start at the same initial amplitude, but are stopped short of vanishing amplitude at different values of field. The Paper then proceeds into an investigation of the effect of varying the frequency of the magnetising reversals, and many diagrams are given summarising the observations. The author's principal conclusion is that the effects recorded are in great measure due to the magnetic shielding effects of the eddy currents induced in the outer layers of the specimen.

Continental

Damping and Resistance in Condenser Sparks.—The laws governing the relation between p.d. and effective current in sparks are discussed by A. Heydweiller, in the *Annalen der Physik*, No. 1. The generally accepted approximate law is $v=a+b/i$, where v is the d.p., i the current, and a and b constants. In oscillating discharges through a low resistance, a is the decisive term, and its measurement is of considerable importance. When the resistance is high, a becomes negligible. The author protests against the misuse of the terms "resistance" and "apparent resistance" in connection with sparks. The former can only mean the resistance of an equivalent solid conductor, and this may be defined either: (*a*) from the damping, or (*b*) from the joule effect, or (*c*) from the relation between v and i. The "apparent resistance," again, has a well-known meaning in alternate-current engineering, and cannot be applied to sparks without ambiguity. The various definitions do not give consistent results. Thus, in air, the damping due to a spark is independent of capacity, and inductance, but not so in a solid conductor. As regards practical questions, the author recommends large, slightly curved electrodes, with a gap of 1 or 2 cm. This gives little damping when the "spraying" is suppressed. . .

Motion of Electrons.—In No. 1 of the *Annalen der Physik* G. A. Schott discusses the mass of electrons and the manner in which it varies when the acceleration varies in a very sudden manner. At low speeds, the mass is practically constant, but a greater mass is associated with an electron when its speed is very high, and this increase of mass may exert a disturbing and complicated effect upon the equations of motion. The theory of Abraham and Sommerfield does not give a clear definition of this mass. If quite sudden changes of speed are excluded, Lorentz's theory gives an exact expression for the mass, not only when the electrons are regarded as rigid, but also when they are flattened out in a direction at right angles to their motion. The usual expression for the radiation pressure applies when speeds beyond the velocity of light are excluded. Otherwise every sudden change of acceleration, or of the curvature of the path, produces subsequently a change in the radiation pressure. The latter is only calculable when the previous history of the electron is known, since it depends upon waves previously emitted. Discontinuities of an order higher than the first produce no effect on either the mass or the radiation pressure. But all this supposes that the electron has left the place of discontinuity by at least a few diameters.

The Interpretation of Spectrum Lines. W. Ritz develops his theory of spectrum lines further in *Bulletin* No. 271 of the French Physical Society. He acknowledges that acceleration cannot be the factor which governs spectrum lines, since, as Rayleigh has shown, it affects the square of the frequency, whereas the observed laws of spectrum lines only imply the frequency itself in the first power. The latter condition may be fulfilled either by supposing that only the speed and the displacement ("elongation") intervene, which is very improbable, or that the determining factors are the acceleration and the speed, but not the displacement. This would make the force proportional to the speed, a relation with which we are familiar in the electron theory of magnetism. Assuming the theory of the internal molecular field produced by magnetic filaments of different lengths, Balmer's law, and the structure of the series is immediately explained. A simple field gives the hydrogen lines. A new parallel field gives a new set of frequencies differing from the old frequencies by a constant amount. This relation is very exact, and may be carried to the fifth or sixth decimal. An external magnetic field produces the Zeeman effect, and triplets, quadruplets, and even Lohmann's sets of 15 components may be deduced from considerations of motion of the molecules.

Magnetic Hysteresis in Rotating Fields.—According to Baily, there is no hysteresis in a rotating magnetic field when that field is very strong. This important result has been confirmed in a more elaborate manner by P. Weiss and V. Planer, who describe their experiments in *Bulletin* No. 271 of the French Physical Society. They used the method adopted by Blondel and Carpentier, but substituted for the permanent magnet an electromagnet, and operated upon a thin iron or nickel disc suspended parallel or at right angles to the axis of rotation of the field. Thus they were enabled to measure both the rotational and the alternating hysteresis. The hysteresis, as usual, was found to be proportional to the couple exerted, and independent of the speed. The field was as intense as 10,000 gauss. In iron and nickel, the rotational hysteresis passes through a maximum and then decreases to zero as the field is increased. At the maximum, the rotational hysteresis is just half the maximum alternating hysteresis. In feeble fields, on the other hand, the rotational surpasses the alternating hysteresis. It is not simply twice the latter, as alleged, but varies from four times down to zero. A field of 7,300 gauss suffices to annul the rotational hysteresis in pyrohotine. This field is also the "chief demagnetising field."

Bournemouth Tramway Purchase.—With reference to the proceedings in the High Courts between the Bournemouth Corporation and the Poole and District Electric Traction Co. (ELECTRICAL ENGINEERING, Vol. II., p. 623), the Corporation has decided to appeal to the House of Lords against the decision of the Court of Appeal (given in ELECTRICAL ENGINEERING, January 30th, p. 170).

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 6th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1906 Patents

25,411. A. F. BERRY. Electrically-heated apparatus for cooking. This specification is printed in full on page 235.

28,628. F. CLARK & J. VLASTO. A controller or starting switch for electric motors, in which the starting resistances are arranged on the axis of the controller, in order to provide the field for the magnetic blow-out and to obviate the use of connections to external resistances. Special arrangements for cooling are provided. Five claims, six figures.

1907 Patents

6,266. THE BRITISH ELECTRIC PLANT CO. & OELSCHLÄGER. Relates to an arrangement of commutating poles on dynamo-electric machines, in which the magnetic circuit of the commutating poles consists of a ring concentric with, and close to the armature, and on which the compensating winding is wound, so as to produce consequent poles at each neutral zone, where short pole-shoes are attached. Magnetic leakage is decreased, and ventilation improved by this device. Three claims, six figures.

7,279. ANGOLD & MAXIM ELECTRICAL COMPANY. An improvement on the type of arc lamp, described in Spec. No. 23,012, 1906. (This specification was printed in full in ELECTRICAL ENGINEERING, Vol. II., page 634.) To obtain a better contact the carbons are gripped by spring-pressed contacts in the feeding tubes, and are thrust down mechanically instead of being allowed to fall by gravity.

9,337. B. NORTH & R. POHL. Improvements in electrolytic meters, in which the quantity of current passing is measured by the change in volume of the electrolyte decomposed by the current. Two or three liquids are used in a two-arm tube; an electrolyte, a measuring liquid, and, if necessary, a separating liquid between the two. The liquids in contact, which must not affect each other chemically, are kept from mixing only by their difference in specific gravity. The measuring tube is inclined for the purpose of increasing the length of scale for a given vertical height. Other minor improvements are included. Seven claims, four figures.

1,003. THE LANCASHIRE DYNAMO & MOTOR CO., LTD., F. G. WARBURTON & A. H. KELSALL. Relates to the field control of flywheel buffer machines for equalising the load on a generator. The armature of the auxiliary machine is connected directly across the mains, but its field winding is in series with the main circuit, and is provided with a diverted shunt, the value of which is automatically altered by variation of main load or speed of auxiliary machine. On a sustained overload this prevents the auxiliary machine from taking an increased current from the generator, and also gives a higher accelerating rate on diminished load. Four claims, three figures.

16,251. A. P. HINSKY. A tubular conduit for electric wires, composed of fibrous material, impregnated with an insulating and preservative substance, and with the outside corrugated circumferentially to render flexible. Two claims, four figures.

20,948. SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*). The use, in transmission systems, of a special earthed conductor, which is connected to the middle or neutral point of the generators or transformers, and is carried in proximity to the line wires. The bare wire is electrically connected to the iron poles or iron insulator pins, or is buried under the poles. It is claimed that the advantages of earthing are obtained without the usual disturbances in adjacent telephone lines, due to leakage currents taking place, as all leakage currents are taken up by the said wire. Two claims, two figures.

24,028. WOLFRAM LAMPEN AKT. GES. Tungsten filaments are decarbonised by heating them in a mixture of dry hydrogen and dry air or oxygen, *i.e.*, a dry process instead of a wet one as formerly. The amount of oxidation of the tungsten itself is lessened. One claim.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

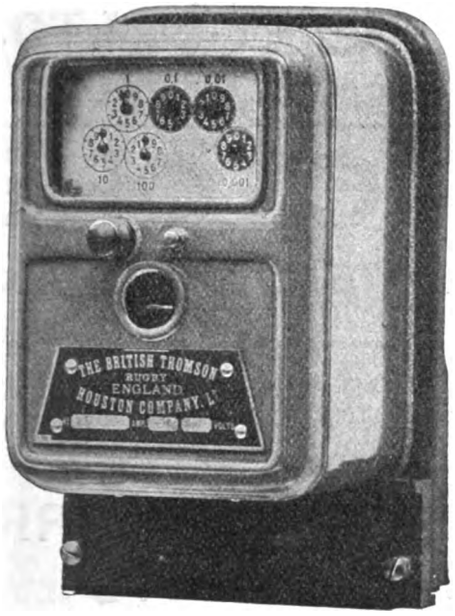
22,920, HATFIELD. Electrolytic cells.
23,016, MACKIE. Dynamo-electric machines for train lighting.
24,084, SMITH. Magnetic compasses.
28,724, OLIVER. Mechanical cars for electrical traction purposes.

1907 Patents

1,197, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Treatment of boron.
1,264, MIURA. Electrical accumulators.
1,356, GANZ & CO. EISENGIESSEREI UND MASCHINENFABRIKS AKT.-GES. Devices for regulating pressure of alternating-current generators.
1,457, MILCH. Control of induction motors.
1,517, MORCOM & WALSHE. Choking coils for testing.
1,608, RADCLIFFE & RADCLIFFE. Mechanical stokers.
1,699, PRATT. Treatment of copper for refining the same.
1,713, ECKSTEIN & HEAP. Fuses.
1,759, RAYMOND-BARKER & AMALGAMATED RADIO-TELEGRAPH CO. Radio-telegraphy.
1,765, PARSONS & CARNT. Methods of securing strips in grooves.
1,781, RAVENSHAW, MIDDLETON & TOWNSEND. Magnetic clutches.
1,866, DRUMMOND. Steam generators.
2,138, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Brush holders for dynamo-electric machines.
2,294, BROWN. Rotary steam generators.
2,417A, CHAMBERS & BENNETT. Electric ignition switches.
2,459, WALKER. Dynamo-electric machines.
2,815, BEST. Safety terminals for electric accumulators.
2,937, CHAMBERS & BENNETT. Apparatus for making and breaking the current in explosion engines.
3,254, VENNER & GRIESBACH. Time switches for electric circuits.
3,483, ELECTRIC IGNITION CO. & HALL. Ignition coils of automobiles.
3,915, REYNOLDS. Electrical-heating apparatus.
4,158, MONARD. Apparatus for operating points and signals.
4,182, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Protective devices for electric circuits.
4,574, OPPERMANN. Secondary batteries.
4,738, ALLGEMEINE ELEKTRICITÄTS-GES. Electric rock drills.
5,066, HANN, INGLE, & DRAKE & GORHAM, LTD. Electric couplings or connections.
5,219, ROYAL-DAWSON. Commutators in internal-combustion engines.
5,334, EISENSTEIN. Production of undamped electrical oscillations.
5,575, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Manufacture of incandescing bodies in electric lamps.
6,057, BILL. Overhead conductors for electric tramways.
6,242, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Systems of electrical distribution employing vapour rectifying devices.
6,716, SIEMENS BROS. DYNAMO WORKS, & WILSON. Dynamo-electric machines.
6,929, SIEMENS & HALSKE AKT.-GES. Electric telegraphy.
7,726, BLACK & THOMPSON. Incandescent vapour lamps.
7,785, KITSEE. Duplexing telegraph lines.
8,205, FOSTER. Relay mechanism for indicating instruments.
8,240, DAMSEAUX. Sockets for incandescent electric lamps.
8,788, RILEY, SEYMOUR, & PERKINS. Automatic signalling.
9,851, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Maximum demand indicators.
10,007, SIEMENS BROS. DYNAMO WORKS & POYNDER. Method of altering the working speed of polyphase motors.
11,072, MARGULIS. Plates for electrical accumulators.
11,673, VON AMMON. Commutators for electrical machines.
13,175, WATKINS, BOLSTER, & GOODSELL. Electric selecting apparatus for telephones.
14,221, MALSON. Electric fuses for use in blasting.
17,947, FALLEK. Automatic electrical gong-ringing device for electrical street railway cars.
19,626, SIEMENS BROS. & CO. (*Siemens & Halske Akt-Ges.*). Electrical locking apparatus for railway signalling.
20,947, SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*). Method of inserting former wound coils of flat copper into slotted iron cores.
23,641, HANWELL. Electric-light pendants.
25,298, DE BRAAM. Arrangements for operating automatic warning and indicating apparatus for stopping trains.
25,402, WHITNEY. Telegraph sounders.

Complete Specifications open to Public Inspection before Acceptance, under the Patents Act, 1901.

1907 Patent



5,508A, LAMME. Connection system for dynamo-electric machines.

1908 Patents

1,344, SALZER. Electrolytic deposition of chromium.
1,364, SOC. ANON. D'EXPLOITATION DES APPAREILS RATEAU. System of automatic pressure control for power installations comprising steam turbines in combination with reciprocating steam engines.
1,547, LANGE. Radio-telegraphy.

Digitized by Google

A.C.T. Induction Wattmeter.

A.C.T. INDUCTION METERS

are designed for recording the energy of either single or polyphase alternating current circuits, irrespective of the character of the loads.

Some of the advantages gained by using these meters are: remarkably low shunt loss, only 0·5 watt for meters up to 250 volts; permanent calibration; ease of adjustment and emovable pivot on spring supported jewel.

APPROVED BY THE BOARD OF TRADE.

LOCAL NOTES

ARGENTINA: *La Plata Tramways.*—The *Review of the River Plate* states that an application has been made to the La Plata municipality for a concession for fifty years for working electric tramways in that city. This new application will, it is stated, cause further delay with regard to the petition for electrification presented by the existing companies.

Telephone Extension.—The La Plata Government has given permission to the Sociedad Co-operativa Telefonica to extend its lines from Quilmes to La Plata, on the understanding that the wires will be placed underground in La Plata within a period of six years.

ASHTON: *Electricity Supply.*—Arrangements having been made with the St. Helens Corporation for the supply of electricity in this district, the current was switched on last week. At present the electrical energy is used for street lighting in a portion only of the district.

AUSTRALIA: *Large Water Power Scheme.*—The *Australian Mining Standard* states that since 1881 a scheme has been in progress for the construction of a dam below the Trawool Railway Station on the Tallarook and Mansfield line across the Goulbourn River, for the purpose of generating electricity in connection with an extensive irrigation scheme. Early in December Mr. W. H. Merz, during his visit to Australia in connection with the electrification of the Melbourne Suburban Railway, made an inspection of the river. The dam will be 1,700 ft. long and 180 ft. high, and will be sufficient to provide a depth of water of 120 feet. An inland lake will thus be formed, with an average depth of 60 ft. covering an area of 25,000 acres. The cost of the scheme is estimated at £230,000, and it is proposed that the Government shall carry out the work.

Prahran-Malvern Electric Tramway Bill.—This Bill, which has been passed by both the Victorian Legislatures, proposes the incorporation of a trust for the construction of tramways in Prahran and Malvern. The cost of the scheme will be about £76,260, but powers to borrow up to £100,000 are provided for in the Bill. The Trust is to consist of five members, a chairman (not a member of either Council) at a salary of £250 per annum, and two Councillors from each municipality, with a remuneration not exceeding £75 to be divided amongst them.

Commonwealth Telephone Service.—A proposal is now being considered by the Government to put the telephone service of the Commonwealth under one permanent head, with a view to securing greater efficiency.

BELFAST: *Whitewell & Cavehill Tramway Bill.*—The result of the poll of the ratepayers of Belfast as to whether the Bill of the Corporation for purchasing the Whitewell & Cavehill tramway undertaking as agreed for £60,000, shall be proceeded with, was a majority in favour of proceeding of 12,158. The actual figures were: for the Bill, 24,733; against the Bill, 12,575.

BOURNEMOUTH: *Trunk Telephone Service.*—At a meeting of the General Purposes Committee last week, a letter was read from the secretary to the General Post Office regarding the trunk telephone service between Bournemouth and London. It was stated that the Postmaster-General had given special attention to the unsatisfactory working of the circuits between London and Bournemouth, which, it was ascertained, was due to branches of trees having blown down on to the lines. The letter also stated that the question of providing additional trunk circuits was also receiving attention.

BRIGHTON: *Safety of Southwick Works.*—At the last meeting of the Brighton Council, the following resolution was on the agenda:—"That it be an instruction to the Lighting Committee to prepare at once and present to a special meeting of the Council a Report as to what steps have and are being taken to meet the wishes of the Shoreham Harbour Trustees in connection with the Electricity Works at Southwick, and the general safety of the building and works." When this was reached, however, it was stated that negotiations were going on, and that any resolution in the Council at the moment might have an effect upon the negotiations. The motion was therefore withdrawn.

BRISTOL: *Tramways Company's Bill.*—The Parliamentary Committee, reporting upon the Bristol Tramways Company's Bill which has been deposited in Parliament this session, points out that only one of the six tramways authorised by the Company's Act of 1904 has as yet been constructed, and that the powers under this Act will expire, as to part of the tramways on August 15th, 1908, and as to the remainder on August 15th, 1909. The present Bill seeks an extension of these powers to August, 1911, and August, 1912, respectively. The committee are of opinion that, as the companies have failed to exercise the powers conferred by their Act of 1904, the further powers now asked for, especially in relation to those areas within the city, should not be granted except on terms and conditions adequate for the protection of the Corporation. The committee, therefore, recommend opposition being made to the Bill. Among the points upon which revision of the existing terms is required is the question of purchase.

BURNLEY: *The New Tramcars.*—The recommendation of the Burnley Tramways Committee to purchase five cars similar to the recent new cars, at an estimated cost of £800 each, was strongly objected to at the Town Council meeting on Thursday. This type of car, it was stated, was known throughout the town as the "screaming car." An amendment to refer the matter back for consideration was carried by 16 votes to 15.

CANNOCK: *Provisional Order Transfer.*—The deed of transfer with respect to the Council's Electric Lighting Provisional Order has been completed and signed, and the purchase money, amounting to £450, has been paid by the syndicate acting for the Shropshire, Worcester, and Staffordshire Electric Power Company.

COLCHESTER: *Exhibition Balance Sheet.*—In a special report concerning the recent electrical exhibition, the electrical engineer said that the expenditure amounted to £200, and the receipts to £171, leaving a deficit of £29.

Vibration from Electricity Works.—Complaints having been received from the tenants of premises near the electricity works of annoyance from vibration, the Corporation has instructed the Electricity Committee to reply, that they do not admit any liability in respect of this.

CROYDON: *Tramway Supply.*—It has been found that the meters for registering the current supplied to the tramways have been working inaccurately. The current shown by the meters as being used was 1·006 units per car mile, whereas it should have been 1·29 units per car mile. The difference will amount, it is estimated, to something like £4,000 per year. At the last meeting of the Council a long discussion took place upon this matter, in the course of which it was pointed out that the great seriousness of the question lay in the fact that they had taken over the trams from the British Electric Traction Co. on the basis of the 1·006 units per car mile. One or two members raised the question as to whether the British Electric Traction Co. could not be made to pay for the extra current which they had used, and which had not been registered by the meters. In the result, no definite action was taken, but it is understood that the Electricity Committee will be approached, and asked to modify the prices at which they are now supplying the current.

DERBY: *Tramway Contractors' Penalties.*—The Tramway Committee reports that under the contract for the construction of the Ashbourne Road and Uttoxeter Road tramways, the Borough surveyor extended the time for the completion to October 24th, 1907, but, as the work was not completed until November 28th, the penalties due from the contractors amounted to £1,465. This sum has been deducted from an instalment due to Messrs. R. W. Blackwell & Co., the contractors in question.

DUNDALK: *Electric Lighting.*—A ratepayers' meeting has been held to consider a resolution urging the Council to proceed with an electric lighting scheme under its Provisional Order. The matter has been discussed for several years past now, and the resolution in question was unanimously carried.

DUNFERMLINE: *Electric Lighting Provisional Order.*—The following are the terms upon which the Fife Electric Power Company will take over the Council's Provisional Order:—(1) The Power Company to pay the Council for their Electric Lighting Provisional Order the amount of expenses incurred by them in connection with the same so far as approved by the Board of Trade. (2) The Power Company would make application for a Provisional Order authorising the transfer of the existing Provisional Order to the Fife Company; the whole costs in connection with the transfer Order to be borne by the Fife Company. (3) The Company would agree to insert a maximum price of 6d. per unit in the transfer Order, and agree on a schedule of rates to be charged consumers for lighting. (4) Detailed terms to be adjusted between Sir Alexander Kennedy, acting for the Corporation, and the Fife Company; failing agreement, subject to arbitration of the Board of Trade. Sir A. Kennedy regards this offer as a reasonable one, and recommends its acceptance subject to the approval of the Board of Trade.

EASTBOURNE: *Osram Lamps.*—The following paragraph appeared in the report of the Electrical Engineer to the Electric Lighting Committee last week:—"The result of the use of 'Osram' lamps has been to reduce the consumption of some consumers using them in place of the ordinary carbon filament lamps in a very marked degree during the past quarter. Taking the average of 17 consumers, the total number of units consumed during the past quarter was 5,297 as against 7,775 for the corresponding quarter last year, a reduction of 32 per cent.; and at the same time the light obtained has been increased by 100 per cent. or more. No doubt the use of such lamps will increase very largely, and as soon as a 200-volt lamp is placed on the market the use of such lamps will increase still more. The result will be that for a time the income will be reduced, but this will be off-set by an increased number of connections following upon the reduced cost of electric lighting."

EAST HAM: *Arc Lamp Hiring Scheme.*—The Electrical Engineer has drawn up a scheme for the hiring of arc lamps under which the Council will provide the lamps, execute the necessary wiring, supply current, and maintain the installation subject to the consumer entering into an agreement to take the current for

Digitized by Google

two years and paying the sum of £2 2s. per quarter per lamp in advance. The committee have adopted the scheme, and have decided to give it a trial. £500 is to be provided for the purpose.

EDINBURGH: *Electricity Works Assessment.*—The dispute between the Corporation and the Edinburgh Parish Council regarding the poor and school rates on the electric lighting undertaking has been settled upon the basis that the undertaking shall be assessed in respect of these rates in the future upon a deduction of 35 per cent. of the total valuation from the annual value of the undertaking. The dispute arose upon the point as to whether the Corporation should be allowed to deduct future depreciation of the plant before making the valuation, whereas the Parish Council contended that the Corporation could only deduct the average amount for depreciation in the past. The parties went to law over the matter, when it was decided that the Corporation's contention was correct. It is in consequence of this decision that the above settlement has been arrived at.

FARNHAM: *Electricity Supply.*—A communication has been received from the Board of Trade to the effect that the revocation of the Farnham Electric Lighting Order, 1905, has been postponed for three months from January 30th. Negotiations are going on between the Council and the Farnham Electric Light Company with regard to putting the order in force, but an obstacle seems to be the proposition of the company to employ overhead wires.

GLASGOW: *Tramway Extension.*—A deputation from the Coatbridge Town Council has waited upon the Glasgow Tramways Committee urging an extension of the Glasgow tramway lines to the centre of Coatbridge. Parliamentary powers will be necessary before the proposed extensions can be made.

GREENOCK: *Opening of Combined Dust Destructor and Electricity Works.*—Last Friday, a combined dust destructor and electricity works was formally opened by Provost Denholm. The destructor is a six-cell one of the Horsfall make, and the hot gases from it are carried through the combustion chamber of a B. & W. water-tube boiler, which is supplemented by coal-fired boilers. The steam pressure is 200 lb. per sq. in. D.C. current is generated by two 250 kw. Belliss-Westinghouse sets, one of which is a three-wire 2×250-volt machine, and the other generates at 500 volts. Two rotary converters are used to supply A.C. current to an outlying district. The station is also connected by trunk cables to the main electricity works, the output of which during last year was about three million units. Mr. J. A. Robertson is consulting and resident engineer to the Greenock Corporation, and the work has been carried out to his specification. We hope to publish a fuller description of the works in our next issue.

HULL: *Resignation of the Chairman of the Electricity Committee.*—At the monthly meeting of the Hull City Council on Thursday, a discussion took place upon the minutes of the Electric Light Committee, which recommended the purchase of three Lahmeyer dynamos. An amendment was moved recommending that the electrical engineer be authorised to prepare a specification for the dynamos required, and that tenders should be invited only from British firms. This amendment was carried by two votes, and, in consequence, Mr. Hanger, the Chairman of the Electric Light Committee, expressed his intention of resigning. Subsequently, Mr. Hanger agreed to remain in office until the question of installing the new machines has been settled.

KIRKCALDY: *Tramway Intercommunication Results.*—Since the scheme for mutual running powers between the Kirkcaldy tramway system and the Wemyss Tramway Co. was put into force on November 17th, 1907, 30,000 additional passengers have been carried upon the Kirkcaldy tramway service up to January 22nd than had been carried during the corresponding period of last year. The receipts have increased by £145, and the saving in expenses owing to the lower car-mileage was £180, making a total increase of £325.

LEEDS: *Municipal Reserve Funds.*—At a meeting of the Corporation on Thursday, a resolution was moved that a Committee be appointed to consider what amount of reserve should be provided in addition to the sinking fund in connection with the tramways, electricity, and other undertakings of the Corporation, the committee to have power to obtain expert opinion and visit such places as they might deem advisable, and to report to the Council. An amendment was moved that the power to call in expert opinion and to visit other places be deleted. Other amendments having been proposed, the original resolution was carried by 27 to 19 votes.

LITTLE HULTON: *Provisional Order Transfer.*—The District Council have decided that the Lancashire Electric Power Co. be permitted to supply electricity to Messrs. E. Bennis & Co.'s works, subject to the completion of the Council's proposed transfer to the company of their Provisional Order.

LONDON: *London County Council.*—At its meeting on Tuesday, the Council decided to proceed with the electrification of the Brixton Road to Camberwell Green tramways, on the overhead system, at a cost of £34,910, of which full particulars were given in our last issue. The Highways Committee stated that they hoped to undertake the electrification of the tramways from Nine Elms Lane to East Hill, Wandsworth, during the financial year 1908-9. The cost of road work is estimated at £158,050, and the committee desired that expenditure amounting to £7,000 be now authorised, in order to facilitate diversions of mains, &c. Under standing orders the report was adjourned for one week.

Hackney: The Draft Home Office Regulations.—The Electric Lighting Committee have received a letter from the Fulham Borough Council asking what action is proposed to be taken with reference to opposing the Home Office regulations for the use of electrical energy in factories and workshops, and being represented at the proposed inquiry to be held at the Caxton Hall, Westminster. The committee report that objections to these rules and regulations have already been lodged with the Home Secretary on behalf of the Council, and that the Town Clerk and Borough Electrical Engineer will represent the interests of the Council at the inquiry.

Islington: London Electric Power Bills.—The Parliamentary and General Purposes Committee recommend petitions being lodged against the London and District Electricity Supply Bill, the London Electric Supply Bill, and the Great Eastern Railway (General Powers) Bill. They hold that the latter should be opposed with a view to preventing the supply of electrical energy by the company at any future time along the line of the Tottenham and Hampstead Junction Railway, of which the Great Eastern Company are joint owners. The Borough Council has endorsed the committee's views on these Bills, and also adopted the proposal that a petition should be presented against the L.C.C. (Tramways and Improvements) Bill, with a view of securing an amendment for a road widening. It has further been decided to petition against the Highgate Hill Tramway Bill, on the ground that the rights of the Council as the highway authority are entirely ignored.

Lambeth: London Electric Power Bills.—The Borough Council decided at the meeting on Thursday to take no action in regard to the three London Electric Bills.

Marylebone: Consulting Engineer's Fees.—The Electric Supply Committee report that the commission paid to Mr. Arthur Wright, consulting engineer, up to date, is £24,614.

Poplar: Oil, &c., Costs.—At the meeting of the Borough Council on Thursday, the electrical engineer reported that the total cost for the current year for oil, waste, engine and boiler house stores will not exceed £155, which is no more than was expended when the undertaking was supplying 3,000,000 units per annum less. The figures for the current year in this respect, with the addition of water, will be 0·01d. per unit, which is unique for this item, and is only achieved by five local authorities and three companies in the United Kingdom.

LOUGHBOROUGH: *Half-year's Statistics.*—The report of the Electricity Committee for the December half-year shows a loss upon the net revenue account of £335. The expenditure amounted to £1,215, and the receipts to £880.

MIDDLESEX: *Edgware-Willesden Tramways.*—The final section of the Middlesex County Council tramways from Edgware to Willesden Junction Station has been completed, and the Board of Trade inspection will take place shortly.

MONMOUTH: *Condition of Distributing Mains.*—Mr. A. W. Blake, the Borough Electrical Engineer, has presented a report in which he recommends that a complete and careful test of each existing section of the low-tension distributing network be made as soon as possible, and records taken of each test, in order to find out definitely where the faults are, and the best way to repair them. He points out it is quite possible that in many places the faults may be repaired without much expense, but in other places he anticipates that complete renewal of the cable will be the only cure for the present unsatisfactory condition of affairs. It is impossible for him to give reliable estimates, but he will endeavour to do so when all the tests have been obtained. Meanwhile he suggests that £200 worth of new cable should be purchased, although the amount required might possibly be greater.

NELSON: *Electricity Supply Charges.*—At a meeting of the Electricity Committee on Thursday representatives of the Brierfield District Council attended and made an application for a reduction in the charges for electricity supplied to their district. The committee agreed to consider the application at the end of the financial year.

ORMSKIRK: *The Electric Lighting Order.*—A letter has been received from the Board of Trade pointing out that, as the Council's Electric Lighting Order granted in 1900 contains no provision for the transfer of the powers, the Board is not prepared to approve of any arrangements for such a transfer. The letter added that, unless the Council could satisfy the Board of Trade that the powers under the Order will shortly be exercised, the Order will not be allowed to remain in force any longer.

SLEAFORD: *Electrical Exhibition.*—An electrical exhibition, which has been organised by the Electricity Department, will be held on February 19th, 20th, and 21st.

WALSALL: *Tramway Accounts.*—The annual accounts of the Walsall Corporation tramway undertaking show a net profit for the year ended December 31st, 1907, of £4,305, which it is recommended shall be transferred to the reserve fund, which already stands at £10,986. The total revenue was £27,356, and

Digitized by Google

the working expenses £15,265. The number of passengers carried was 4,860,764, the average revenue per car mile 10·63d., and the working expenses 6d. per car mile.

Electricity Accounts.—The balance sheet of the electrical department for the past year shows a loss of £89, compared with a profit of £703 during the previous year. The increased price of coal is given as the main cause of this result, other contributory factors being increased payment on capital account, and the reduced price of current.

WEDNESBURY: *Electricity Supply.*—At a meeting of the Town Council last week, the action of the Electricity Committee in its negotiations with the Midland Electric Corporation for Power Distribution, reported in our last issue, was approved.

WEST HAM: *London Electric Power Bills.*—The Legal and General Committee recommend that petitions be presented against the London and District Electricity Bill, the London Electric Supply Bill, and the Great Eastern Railway Bill. In regard to the first-named measure, the electrical engineer reported to the committee that there were still, with as much force as ever, the old arguments. Relative to both Bills, the tramways manager reported the necessity of protection as to the breaking up of the tramways and compensation for any dislocation of tramway traffic. In their report on the Great Eastern (General Powers) Bill, the Council's solicitors said it was entirely outside the purpose for which a railway company was incorporated that it should have power to sell electricity. The provisions would give the company power to compete extensively with the Corporation's electricity undertaking, and, further, as the company could not be compelled to give a supply to anyone, it was safe to assume that they would only supply in cases where a profit would be likely to be made, leaving the unprofitable supplies to be given by the authorised electrical undertakers.

WESTHOUGHTON: *South Lancashire Tramways.*—The South Lancashire Tramways Co. has offered to transfer to the Council the powers which the company possesses to construct tramways in Westhoughton, and which will otherwise expire in July. A sub-committee has been formed to confer with the Bolton tramways committee concerning the proposition.

WORCESTER: *Hiring Out of Motors, &c.*—The Electricity Committee recommend that the Corporation should join the Hastings Corporation in urging the necessity of legislation enabling local authorities owning electricity undertakings to hire houses upon the hire-purchase system, as also to hire out motors.

YORK: *Electricity Accounts Deficiency.*—At the last meeting of the City Council, the Lord Mayor in reply to questions regarding the deficit of £8,809 upon the electricity undertaking, stated that the major portion of it arose in connection with the working, and the remainder was an overdraft upon the banking account through credit being given to consumers.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ABERTILLERY.—The Local Government Board inquiry into the application of the District Council to borrow £10,000 for electric lighting purposes was resumed on Thursday. Mr. Lloyd, of Messrs. Medhurst & Lloyd, consulting engineer, said it was proposed to erect 191 street lamps, and to employ overhead wires wherever practicable. The estimated cost of the scheme was £10,362, and he anticipated that the receipts would balance the expenditure at the end of the first year. In fact, he anticipated it being necessary to apply for an additional loan in about eighteen months' time. There was some opposition on behalf of the ratepayers' association. The inquiry was concluded.

ASTON.—A scheme for the extension of the electricity works at a cost of £25,213 has been approved.

Tenders are invited for a 2,000 kw. turbo-alternator with condenser, air, and circulating pump. Full particulars from Mr. R. Foster, Borough Electrical Engineer, fee £1 1s., returnable, and tenders to the Town Clerk by February 17th.

AUSTRALIA.—The *Australian Mining Standard* states that the Commonwealth Treasurer announces that the Postmaster-General has made urgent appeals to him for additional funds, amounting to £102,418, for development in telephone and telegraph services. In New South Wales ordinary telephone extensions call for £34,000; special trunk lines from Sydney to Wollongong, Katoomba, and Gosford, £6,598; and Sydney-Tenterfield extension of telegraph line to meet the Queensland line, £11,960—a total of £52,558. Victoria requires £33,240 for underground telephone extension; Queensland wants £5,526; and South Australia £11,094.

BARKING.—The Council invite tenders for the supply and delivery of electrical sundries, carbons, meters, &c. Full particulars from the Electrical Engineer's office, East Street, and tenders to the Town Clerk by February 25th.

BELFAST.—Tenders are invited by the Corporation for the supply of low-tension cable during the twelve months ending March 31st, 1909. (See advertisement this week.)

In connection with the alternative schemes which have been received by the Belfast Board of Guardians for the lighting of the Abbey Sanatorium at White Abbey, Mr. W. W. Lackie, electrical engineer to the Glasgow Corporation, has received permission to advise.

BLACKBURN.—The Electricity and Tramways Committee invite tenders for the supply of the following stores during the year ending March 25th, 1909:—General stores (including paints, varnishes, &c.), iron brass castings, bolts, bars, &c.; timber; glass; insulating material; tools, brushes, &c.; oils, &c.; wrought-iron pipes; house service fuse boxes, switches, &c.; motors; motor starting switches; screwed tubes for inside wiring. Specification and forms of tender from the Borough Electrical Engineer, and tenders to the Chairman of the Electricity Committee by February 15th.

Montague Street Baptists, Blackburn, have decided to erect a new church. Mr. F. J. Parkinson, of Blackburn, is the architect, and electric lighting will be adopted.

BOURNEMOUTH.—An additional electric lift is to be provided on the West Cliff.

BRISTOL.—The Docks Committee invite tenders for the supply, delivery and erection, and maintenance for 12 months after they have been in use, of electric cables for the supply to Avonmouth Docks. The tenders are also to include the construction, delivery, erecting in place, fitting, completion, and testing and the maintenance for 12 months after they shall have been taken into use of the electric lighting installations, complete in all details, for the various buildings, railway yard, wharves, &c., at the Royal Edward Dock, now in course of construction at Avonmouth. Specifications, &c., from the Secretary of the Docks Committee (fee £5, returnable), and tenders to 19 Queen Square, Bristol, by February 17th.

BURNLEY.—At the Town Council meeting on Thursday, the Chairman of the Electricity Committee submitted a resolution, which was passed without criticism, that a 750 kilowatts steam generator at a cost of £6,835, and a motor-driven centrifugal pump for cooling and condensing purposes at a cost of £265, be obtained. The Town Clerk was also directed to apply to the Local Government Board for their sanction to the borrowing of the necessary money, and to the repayment of the money within a period of twenty-five years.

DARWEN.—The tender of Mr. O. C. Burnley for advertising on the Darwen electric cars shortly expiring, the Council have decided that fresh tenders be obtained.

GRAVESEND.—Stores are required by the Electricity Department as follows:—Small coal, engine stores, oil stores, lamp stores, carbons, and meters. Specifications, &c., from the Borough Electrical Engineer, and tenders to the Town Clerk by February 17th.

GLASGOW.—The Tramways Department invite tenders for the supply and erection of two movable bridges over the Forth and Clyde Canal at Dalmuir and Kilbowie. Full particulars from the General Manager, 46 Bath Street, Glasgow, and tenders to the Town Clerk by April 13th.

HANDSWORTH.—Tenders are invited for (*a*): 315 kw. generating set, (*b*) feed-pump economiser and pipe work, (*c*) switchgear for 315 kw. generating set. Full particulars from Messrs. Kennedy & Jenkin, 17 Victoria Street, fee £3 3s., returnable, and tenders to the Town Clerk by March 4th.

HOLYHEAD.—A Local Government Board inquiry was held last week into an application by the Urban District Council to borrow £3,000 for electric lighting purposes. In dealing with the figures relating to the works, the inspector pointed out that whereas the loan sanctioned amounted to £20,000, the capital expenditure was £24,213. There was a bank overdraft of £998, but he could find no reference to the remaining £215. As none of the officials appeared to be in a position to give an answer to this question, and the electrical engineer stated he did not know, the inquiry was adjourned, the inspector stating that he would come down again when a proper statement had been prepared for him.

ILFORD.—Tenders are invited for the supply and delivery of a 1,000-kw. steam generator, watertube boiler, &c. Particulars from the Council's Electrical Engineer, and tenders by February 28th.

LEEDS.—Tenders are invited for the supply of steam coal for the generating set for six, nine, or twelve months' supply. The consumption is approximately 500 tons per week; also for the supply of household coal and delivered at the various offices and depôts as required. Particulars may be obtained from the General Manager, at the Tramway Offices, City Square, Leeds, and tenders should be sent to the Town Clerk not later than February 21st.

The tramways Committee invite tenders for the supply and erection of steel and currugated iron buildings at their depôt in Sovereign Street. Full particulars from the General Manager (fee £2 2s., returnable).

LEIPSIG.—The Town Council has decided to erect electric lighting and power works at a cost of £1,000,000.

LONDON: *Bermondsey.*—Tenders for the supply of the following stores during the year ending April 1st, 1909, are invited:—Arc lamp carbons and brushes, cable and fuzing

Digitized by Google

material, conduits, electricity meters, demand indicators, and main fuses, engine oils, meter boards, street frames and covers and joint boxes. Full particulars from the Electrical Engineer, and tenders to the Town Clerk by February 17th.

Battersea.—The Council invite tenders for the supply of stores as follows, for the year ending March 31st, 1909 :—Oils, engine room stores, coal, carbons for arc lamps, electricity meters, service joint boxes, ironmongery, tools, &c. Particulars from the Electrical Engineer, Electric Light Station, Lombard Road, Battersea, and tenders to the Town Clerk by February 18th.

Hammersmith.—The following stores are required for the Electricity Department during the twelve months ending March 31st, 1909 :—Arc lamp gloves, &c., brooms and brushes; electrical goods; files; fire bricks; clay and lime; gauge glasses; insulated wires; metals; meters; oilman's goods; packing and jointing materials; screws and tools. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 19th.

Fulham.—The Guardians invite tenders for electrical requisites, among other supplies, for the year ending March 31st, 1909. Samples and patterns can be inspected at the Guardians' offices, 129 Fulham Palace Road, Hammersmith, between 10 and 12 and 2 and 4 o'clock. Tenders to the Clerk not later than February 27th.

Islington.—The Borough Council invite tenders for the supply of the following stores during the year ending April 1st, 1909 : Engine-room stores, &c., arc lamp carbons and globes, oil, transformers and accessories, &c.; electricity supply meters, prepayment meters, cables; electrical sundries; lamps, brushes, arc lamp parts, &c.; terminal service and network boxes. Particulars from the Town Clerk, to whom tenders by February 18th.

Tenders are also invited by February 25th for (*a*) one 1,500-kw. steam-turbine alternator, &c., (*b*) water-tube boiler, conveyor, &c. (See advertisement this week.)

Southwark.—The Borough Council decided at its last meeting to extend the feeder cable in Walworth Road to the end of Sutherland Place, at a cost, including provision of pillar and switchboard, of £180, and, having regard to the low price of copper, to invite tenders at once.

LOUGHBOROUGH.—An application is to be made to the Board of Trade for sanction to borrow £5,000 in respect of the electricity undertaking.

MANCHESTER.—The Electricity Committee invite tenders for the supply, delivery, and erection at the Stuart Street generating station of four water-tube boilers and accessories. Full particulars may be obtained from the Secretary of the Electricity Department at the Town Hall, fee £1 1s. returnable, and tenders to the Chairman of the Department by February 25th.

NELSON.—The Town Council has decided to obtain tenders for the supply of oilskins for the light railway drivers and of uniforms for inspectors, drivers, and conductors. A sub-Committee was appointed with full authority to act.

NEWCASTLE EMLYN.—The question of providing an electrical installation is under discussion by the council.

RAWTENSTALL.—Tenders are invited for the supply, delivery, and erection at the Electricity Works of an overhead travelling crane, and of a battery of accumulators, automatic reversible booster, and accessories. Particulars and tender forms may be obtained from the offices of Messrs. Lacy, Sillar & Leigh, 2 Queen Anne's Gate, Westminster, S.W., fee £2 2s. returnable, and tenders to the Town Clerk by February 21st.

REDDITCH.—A Local Government Board inquiry was held last week into an application by the Council to borrow £1,500 for the extensions to the electricity undertaking. £1,000 is for cables, and £500 for meters.

SALFORD.—An application is to be made to the Local Government Board for sanction to borrow £20,000 for tramway purposes.

The Tramways Committee invite tenders for an additional electric light installation at the Central Depot in Frederick Road, Pendleton. Full particulars from the General Manager, 36 Blackfriars Road (fee £1 1s., returnable), and tenders to the Town Clerk by February 17th.

STALYBRIDGE.—The Stalybridge, Mossley, Dukinfield, and Hyde Joint Electricity Board have decided to apply for sanction to borrow £20,223 for additional plant at the generating station, and £5,000 for the purchase of transformers to meet the increasing demand.

SWANSEA.—Tenders are invited for the supply and delivery of motors and starting switches during the ensuing year. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by February 21st.

SWINDON.—The Electrical Engineer has reported with regard to the advisability of extending the plant at the generating station in order to meet the increasing demand, and the committee have instructed him to prepare plans, specifications, and estimates of the proposed extensions.

TORQUAY.—In consequence of the increased demand of the tramway company, the council is in doubt as to whether it will be possible to extend the present electricity works. The only alternative seems to be the revival of the scheme put forward a year or two back for a new station at Upton, which, it is estimated, will cost about £20,000. A report is being prepared by the Corporation's Consulting Engineer.

WIMBLEDON.—The Corporation invite tenders for the supply and erection of the undermentioned plant at their electricity works, and are prepared to accept tenders subject to the sanction of the Local Government Board being obtained for the necessary loan :—(*a*) A 1,000 kw. turbo-alternator, with condensing plant; (*b*) two water-tube boilers, economisers, pipe-work, and feed pump; (*c*) high-tension main switchboard and switchboard gallery. Forms of specification and tender, with the general conditions, may be obtained from Mr. H. Tomlinson-Lee, the Borough Electrical Engineer, Electricity Works, Durnsford Road, Wimbledon (fee £1 each specification, returnable), and tenders to the Town Clerk by February 18th.

WORCESTER.—A Local Government Board inquiry has been held into the application by the City Council to borrow £10,000 in connection with the electricity undertaking. During the proceedings, it was stated that this sum was required for extensions to the boiler-house, and to a smaller extension in connection with the pump-house. The boiler-house extension, however, it was not proposed to carry out this year. The inspector thereupon stated that the Local Government Board was not prepared to sanction a loan for the boiler-house extension until it was necessary to carry out the work, but asked for the expenditure upon the two sections to be worked out, and that upon the pump-house to be submitted to him.

TENDERS RECEIVED AND ACCEPTED

"ARON" TAXIMETERS.—The General Electric Co., Ltd., have received through the Federation of Associated London Cab Proprietors a contract for the supply of one thousand taximeters for horse-drawn cabs, and during the present month a number of these instruments will be seen on vehicles plying for hire on the London street. This taximeter is made by the manufacturers of the well-known electricity meter, and has been approved by Scotland Yard, besides passing the severe tests of the National Physical Laboratory. The General Electric Co. have also received a number of orders for these taximeters from other cab proprietors in London and the provinces. Special arrangements have been made at the company's works at Southwark, Hammersmith, and Kilburn for the fixing and adjusting of the instruments.

DERBY.—The tender of the Otis Elevator Co., Ltd., has been accepted for the supply and erection of an elevator at the new power station at £150.

LONDON: *London County Council.*—The Council has received the following tenders for the laying of cable ducts in connection with the electrification of the Caledonian Road tramways :—Dick, Kerr & Co., Ltd. (accepted), £3,375 17s. 8d.; Clift Ford, £3,754 14s. 10d.; W. Muirhead & Co., £3,748 4s. 1d.; D. R. Paterson, Ltd., £3,804 8s. 11d.; Westminster Construction Co., Ltd., £3,881 10s.; John Mowlem & Co., Ltd., £4,069 4s. 5d.; Greig & Matthews, £4,196 19s. 5d.; Callender's Cable & Construction Co., Ltd., £4,200 11s. 3d.; Reed Bros., £4,559 7s.; Fry Bros., £4,741 15s. 3d.; J. A. Ewart, £4,811 3s. 10d. For the supply of low-tension cables required for the work, the following tenders were received :—Johnson & Phillips, Ltd., £4,020 18s. 4d.; British Insulated & Helsby Cables, Ltd., £4,056 18s. 3d.; Western Electric Co., £4,070 2s. 2d.; Siemens Bros. & Co., Ltd., £4,093 17s. 9d.; W. T. Henley's Telegraph Works Co., Ltd., £4,118 16s. 10d.; Callender's Cable & Construction Co., Ltd., £4,148 16s. 3d.; W. T. Glover & Co., Ltd., £4,401 16s. 11d.; Union Cable Co., Ltd., £4,768 18s. 10d.

The Council has also accepted the tender of Pfeil & Co. at £94 10s. for a power-driven lathe for the electricity undertaking.

Chelsea.—The Borough Council has accepted the tender of the Alliance Electrical Co., Ltd., to carry out quarterly inspections of the electric light installation in the pubic baths for 10s. 6d. per annum.

Holborn.—The Board of Guardians has accepted the tender of J. W. Gray & Son for the following work :—To repair, reinstate, and keep the telephonic installation in working order for twelve months from the date of completion as per specification, £36 net; to provide and fit extra 15-line switchboard in the apartments of the workhouse master, £2 10s.; to undertake, after the expiration of the first year, the maintenance of the installation, £5 5s. per annum.

Hackney.—The Public Libraries Committee have received the following tenders for inter-communicating telephones at the Central Library :—Higgins & Griffiths, £53 10s.; Fryer & Co., £40; J. H. Golding, £33 7s.; Smith & Co. (provisionally accepted), £26 18s.

Stepney.—The Borough Council has placed an order with

Digitized by Google

W. & T. Henley's Telegraph Works Co., Ltd., whose tender was recently accepted for the annual supply of cable, for a size not specified in the contract (7/18 concentric paper insulated lead-covered cable) at £98 per mile, subject to the rise and fall in the market prices of copper and lead.

EAST HAM.—The Town Council have received quotations from the United Car Co. and Milnes, Voss & Co. for providing and fitting roof coverings to five or alternately ten tramcars, and have accepted the quotation of Milnes, Voss & Co. for covering ten cars at £90 per car.

GLASGOW.—The Electricity Committee recommend the acceptance of the tender by Messrs. Willans & Robinson, Ltd., of £32,043 for two 400 kw. turbines with "Centraflo" condensers and Dick-Kerr alternators.

SWANSEA.—The tender of Messrs. J. & D. Jones, of Swansea, has been accepted for the erection of a stores and test-room at the electricity works.

WORCESTER.—The following tenders have been accepted:—The Electric Construction Co., 400 kw. generator, with Bellis & Morcom engine, £2,262; W. H. Allen, Son & Co., condenser, air, and circulating pumps, £925; Phœnix Dynamo Manufacturing Co., balancer, £125.

COMPANIES' MEETINGS AND REPORTS

ANGLO-AMERICAN TELEGRAPH.—The half-yearly report shows that the total receipts from July 1st to December 31st, 1907, including the balance of £24,142 19s. 3d. brought forward from the last account, amounted to £235,935 4s. 9d. The traffic receipts show a decrease of £7,798 as compared with the half-year ended December 31st, 1906. The working expenses of the half-year amounted to £73,456 11s., being a decrease of £3,049 12s. 10d. as compared with the corresponding period of 1906. The sum of £20,000 has been added to the renewal fund, leaving a balance of £142,478 13s. 9d. Quarterly interim dividends of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, were paid on November 1st last, absorbing £52,500, leaving a balance of £89,978 13s. 9d., out of which the directors recommend the proprietors to declare final dividends of £1 5s. per cent. on the ordinary stock, £1 10s. per cent. on the preferred stock, and £1 per cent. on the deferred stock, payable on February 8th, amounting together to £87,500, making a total distribution for the year ended December 31st, 1907, of £3 10s. per cent. on the ordinary stock, £6 per cent. on the preferred stock, and £1 per cent. on the deferred stock. The balance of £2,478 13s. 9d. will be carried forward to the next account. The renewal fund has been debited with £90,000 as a provision on account of depreciation of the securities, and this sum has been deducted from the cost of "sundry securities" in the balance sheet and carried to a depreciation account.

At the meeting on Friday the report and accounts, given in our last issue, were adopted. With reference to the loss in traffic receipts of £8,000, Mr. F. A. Bevan, the chairman of the company, who presided, said that whilst commercial receipts had diminished, there was a very large increase in Press news. Referring to wireless telegraphy and the fact that the Marconi Company now accepted private messages at 7½d. per word as against 1s. per word charged by the Anglo-American Company, the chairman stated that he was not informed how much business was transacted; and although it was early to judge of results, they appeared to have suffered no diminution in consequence. Even assuming that the Marconi Company could deal with their traffic as quickly as the cable companies, he pointed out that there were sixteen cables across the Atlantic, each of which could send messages from both ends at the same time. He did not believe that the Marconi Company could work at this rate; and even if they could, they could only deal with 1/32 of the whole traffic.

BRUSH ELECTRICAL ENGINEERING.—A general meeting of the 4½ per cent. perpetual debenture-holders was held on Thursday to approve a resolution approving the scheme for consolidating the company's debenture stock, which, as pointed out last week, at present consists of £125,000 first and second debentures into £237,000 new 4½ per cent. consolidated stock, and the issue by public subscription of a further £112,500 of similar stock. Owing to the absence of the necessary quorum, the meeting was adjourned for a week. A meeting of the holders of the £125,000 4½ per cent. second stock was afterwards held, and after some discussion it was decided to adjourn this meeting also for one week in order to ascertain the decision of the first debenture-holders.

CENTRAL LONDON RAILWAY.—The ordinary general meeting was held on Wednesday last, Sir Henry Oakley, chairman of the company, presiding. The report and accounts given in our issue for January 30th were adopted. In going through the accounts, the chairman stated that there had been no alteration in the capital powers, although they anticipated having to spend about £50,000 upon the completion of works already undertaken; but this expenditure would not be incurred at present. There was, however, the question of dealing with the £25,300 which stood in the accounts as Parliamentary expenses. This sum had been incurred in connection with the various proposals before Parliament to extend the line, but the Board had now come to the conclusion that, for the present, it was not expedient to go on with this proposition. He thought the amount in question was clearly a revenue charge, and must be so allocated. Fortunately, they had put on one side about £10,000 per annum as a reserve fund, and the Board proposed that the amount of £25,300 should be charged against this, thus leaving a balance of £72,000. With regard to the loss upon the sale of the original locomotives, the Board had decided to treat this as a capital loss, and as part of the original construction of the line. Dealing with the loss in the number of passengers carried, Sir Henry Oakley said this had puzzled the Board so much that they had conferred with all the best men available in order to see whether it could be assigned to any special cause. Eventually the omnibus companies were negotiated with, and arrangements come to that if the Central London retained its twopenny fare, the fares upon the omnibus routes would be increased so that they did not encroach upon the company's main business, namely, the twopenny fare. So far their experience of this arrangement showed indications that they were regaining a portion of their passengers previously carried to and from Tottenham Court Road, and which they presumed had been transferred to the omnibus companies by the attraction of the penny fare. This was one step they had taken towards improving their business. Another step was an arrangement with the Baker Street and Waterloo Railway, and the Charing Cross, Euston, and Hampstead Railway, for through booking. These arrangements had practically opened a new source of traffic, for the number of passengers carried from off these lines amounted to from 10,000 to 12,000 per day. They were also in treaty with the City and South London Company for a similar arrangement, and also the Great Northern, Piccadilly, and Brompton Railway. In connection with the latter, however, there were physical difficulties at the Holborn station which would involve a large expenditure before the arrangements could be carried out. Under all the circumstances he thought that the small diminution of £4,000 in their net result was not, on the whole, to be very much deprecated.

CITY & SOUTH LONDON RAILWAY.—The ordinary general meeting was held on Tuesday, Mr. Stuart Wortley, K.C., M.P., presiding. He stated that the half year under review was the first during which the extension to Euston had been opened, and their traffic receipts showed an increase of £6,376. Against this, however, had to be set items of £1,135 for extra debenture interest, £3,750 for new interest on the 1903 preferred stock, and £1,381 interest on other borrowed money. In addition, they had ceased to receive the interest from the contractors on money raised by the company, making a sum of £9,592 extra charges, which they had to meet in consequence of the opening of the new line. The number of passengers carried had increased by 18 per cent., and the receipts per passenger had been 1·78d. against 1·79d. for the corresponding period of last year. The rate of increasing traffic during the first weeks of the opening of the new extension had not been maintained, but this he attributed to the wet summer of last year, and the fact that in consequence people were not tempted to take advantage of the facilities for visiting the open country, which the Euston extension afforded in connection with the other railways which it joined up with. Further, the electrification of the London County Council tramways in the north of London must lead them not to expect so great a share of this traffic in the future as they had had in the past, especially in respect of traffic created by the exhibitions at the Agricultural Hall. He hoped, however, that they had now seen the worst effect of municipal competition between Moorgate and Islington. The report and accounts given in our last issue were adopted.

DUBLIN UNITED TRAMWAYS.—At the meeting last week the report and accounts, given in our issue for January 30th, were adopted. The chairman, Mr. W. M. Murphy, stated that the gross receipts were £170,851, compared with £138,818 of the corresponding half-year of 1906, an increase of more than 23 per cent. The cost of working had increased by only 16 per cent. He had to point out, however, that they had now nearly reached the end of their cheap coal contract, entered into more than two years ago, and that for future supplies they would have to pay an increase of 5s. per ton. The balance of revenue over working expenses was nearly £20,000 more than in 1906, namely, £86,348, which, together with the £1,200 brought forward, left an available balance for distribution of £21,200 in excess of the balance available in the second half of 1906. The net sum available, after all charges were made, was £13,000. In order to provide for the reconstruction of a portion of the line to Blackrock it was proposed to appropriate £10,000. Dealing with the complaint of overcrowding during the rush hours of the day, Mr. Murphy, in order to dispose of any feeling that the public of Dublin were not as well provided for as they ought to be, pointed out that there was more tramway accommodation in Dublin in proportion to the population than existed in any other city in the United Kingdom.

Digitized by Google

GREAT NORTHERN & CITY RAILWAY.—The report and accounts, given in our last issue, were adopted at the half-yearly meeting on Thursday. The Earl of Lauderdale, chairman of the company, who presided, stated that for the first time since the line had been opened it had failed to show a steady progress in receipts and passengers carried. The falling off in passengers was 358,749 compared with the corresponding half-year, and the gross receipts had been decreased by £785. Whilst not attempting to disguise their disappointment at the set-back in the company's progress, the directors wished to state that nothing had occurred in the system or its working to account in any way for the falling off; the diminution was almost absolutely due to the opening up of new routes. While the Great Northern, Piccadilly Brompton Railway and the City & South London Railway to King's Cross were partly responsible, the most important factor had been the competition of the London County Council tramways. In July, 1907, the electric tramway service to Highbury had been inaugurated, and from that date onwards there had been a steady decline in the number of passengers carried. The fares had been increased, but it had only resulted in checking the decrease in revenue. Had they continued at the old fares they would have had a loss of £2,000 instead of £785. The one unsatisfactory feature of the competition by the London County Council tramways was the feeling that the undertaking was not carried on upon a commercial basis, and that too low fares were being charged. He did not think the company could increase its fares in the face of the present competition, but he could only hope that they had seen the lowest point of their passenger traffic.

LONDON, BRIGHTON & SOUTH COAST RAILWAY.—At the ordinary general meeting on Wednesday last week, the chairman, Lord Cottesloe, was asked what attitude the company intended to take up with regard to the conversion of electric traction of the East London Railway, of which undertaking the London, Brighton & South Coast Railway is a lessee. The chairman replied that he thought the Brighton Company had quite enough to do at present in connection with their own electric scheme, especially as this might possibly lead to further work of this description upon their own lines in the future.

NATIONAL TELEPHONE.—The report of the half-year to December 31st, 1907, shows that the income amounts to £1,387,189, as compared with £1,241,843 for the corresponding period of 1906, being an increase of £145,346. The working expenses for the half-year amount to £780,332, compared with £710,492 for the corresponding period of 1906, an increase of £69,840. The net result for the half-year (after deducting the Post Office royalties amounting to £132,621 2s. 2d. is a profit balance of £474,236, as compared with £412,851 for the corresponding period of 1906, or an increase of £61,385. The rentals carried forward for unexpired terms of running contracts amount to £1,168,389, compared with £1,057,806 at the corresponding period of 1906, an increase of £110,583. Out of the available balance of £369,888 shown by the net revenue account, the board recommend the payment for the half-year of a dividend at the rate of 6 per cent. per annum on the first and second preference shares, 5 per cent. per annum on the third preference shares, 6 per cent. per annum on the preferred stock, and 6 per cent. per annum on the deferred stock and new shares, less income tax in all cases. It is also proposed to transfer £145,000 to the reserve fund account, and to carry forward the balance of £10,438. The sum of £545,752 has been expended on capital account during the half-year in the erection of 18,405 additional exchange and private stations, and in the construction of underground works. The meeting will be held on the 20th inst.

NORTH-EASTERN RAILWAY. The half-yearly report for the period ended December 31st, 1907, shows expenditure upon electric train working of £17,467, compared with £17,035 during the corresponding period of 1906. No separate figures are given for receipts from the electrically-worked lines.

SMITHFIELD MARKETS ELECTRIC SUPPLY.—The report for the year 1907 shows gross profit amounting to £5,195, compared with £5,135 8s. 8d. of last year, and net profit £3,337, compared with £3,172, an increase of £165. This balance it is proposed to carry to the general reserve fund. The directors regret that they are still unable to recommend the payment of a dividend for the reasons already given at the last meeting of the shareholders. [This refers to the uncertainty as to the attitude of the City Corporation at the expiry of the company's Provisional Order.] The output of the station shows an increase over the previous twelve months, but the high price of coal during the latter half of the year has had a material effect on the profits. The directors have been successful in obtaining a reduction of £700 in the rating of the company's generating station, the full benefit of which will accrue during the current year. The meeting will be held on the 21st inst.

SOUTH-EASTERN & CHATHAM RAILWAY.—At the half-yearly meeting last week, the Chairman, Mr. Cosmo Bonsor, stated that the passenger receipts continued to decrease considerably. During the half-year to December 31st, 1907, they had carried 2,250,000 fewer passengers than in the corresponding half-year of 1906, and the reason for this was the competition of the electric trams in the London suburban district, where the decrease in traffic mainly took place. He was afraid they would have to recognise that they could not meet this competition, and, consequently, the only thing to do was to make economies.

PARLIAMENTARY INTELLIGENCE

BELFAST CORPORATION AND CAVEHILL TRAMWAYS.—In the House of Commons on Monday, Mr. Devlin asked the Chief Secretary to the Lord Lieutenant of Ireland a number of questions regarding the proposed purchase of the Cavehill and Whitewell Tramways Co.

Mr. Birrell, in a printed reply, said that the Local Government Board had no information in regard to the matters of fact alleged in the question, but it had been furnished by the Town Clerk of Belfast, with the following statement on the subject:—A plebiscite was taken in regard to the proposed purchase of the Cavehill and Whitewell tramways, and it resulted in favour of the confirmation of the agreement for purchase by a majority of 12,158 votes. The Corporation have no information as to any connection between Messrs. White & Company and the British Electric Traction Company, and all dealings of the Corporation in reference to the purchase of the tramways were with the Cavehill and Whitewell Tramways Company alone. The cost of reconstruction and electrification had been estimated at over £40,000, in addition to the £13,523 paid for the old horse line. Two members of the Council are shareholders in the Cavehill and Whitewell Tramways Company. One of them, Mr. Robert Dunlop, is a director of that company. Neither he nor the other shareholder took any part or voted in the Council on the negotiations for the purchase by the Corporation. Mr. Nance was chairman of the Cavehill and Whitewell Tramways Company previous to 1904, but then resigned his chairmanship and parted with his shares, severing his connection with the company. The last balance sheet of the company showed the capital outlay on the old line as £13,523 odd, but did not state the traffic receipts for the 48 weeks ending December 6th last. When the line is worked by the Corporation, in conjunction with their own tramways, it is expected that there will be a considerable increase without corresponding additional outlay, and that the line will be a paying one. Mr. Birrell continued that the matters referred to in the questions would be rather for the consideration of the Parliamentary Committee before whom the Bill would come than for the Board.

DUBLIN AND CENTRAL IRELAND ELECTRIC POWER BILL.—The Dublin Corporation has decided to petition against this Bill, in spite of the fact that there is a protecting clause already in it.

LONDON ELECTRIC POWER BILLS.—The London and District Electricity Supply Bill was read a second time in the House of Lords on Monday. The Barking Urban District Council has petitioned against this Bill. *The Times* states that the London Liberal members of Parliament have decided to form sub-committees, one of which is to deal with the question of electric power supply in the metropolis.

NATIONAL PHYSICAL LABORATORY.—In the Parliamentary papers last week a notice appeared stating that a copy has been presented of the report of the Committee appointed by the Treasury to inquire generally into the work now performed by the National Physical Laboratory, together with a Treasury minute dated February 1st, 1908, recording their lordships approval of the recommendation contained in the report of the majority of the Committee.

PETITIONS AGAINST BILLS.—The Lancashire Electric Power Co. have petitioned against the Burnley Corporation's Bill.

PROGRESS OF ELECTRIC BILLS.—The Doncaster Corporation Bill, and the Leeds Corporation Bill were read a second time in the House of Commons on Monday. The following Bills have been read a first time in the House of Lords:—South Wales Electrical Power Distribution; the Keighley Corporation; King's College, London (transfer); London and District Electricity Supply; London County Council Tramways.

RADIO-TELEGRAPHIC CONVENTION.—In reply to a question in the House of Commons by Mr. Arthur Lee on Wednesday last week, The Postmaster-General stated that the formal ratification of the Radio-Telegraphic Convention on behalf of Great Britain had not yet been deposited. It would be necessary, however, in order that advantage might be taken of the provision as to the exemption of stations, that notice of the reservation of the right of exemption should be given before March 31st. He saw no reason why the decision of Great Britain to ratify the Convention should be modified, in view of newspaper statements as to the possible action by other countries. As a matter of fact, there was an understanding that the Convention would not be ratified without simultaneous ratification by certain other Powers, but these did not include the United States.

The British Association.—The following are among those who have been elected by the Council of the British Association to be presidents of sections at the meeting of the Association to be held in Dublin in September next, under the general presidency of Mr. Francis Darwin, F.R.S.:—Section A (Mathematical and Physical Science), Dr. W. N. Shaw, F.R.S., Director of the Meteorological Office; Section B (Chemistry), Prof. F. S. Kipping, F.R.S., Professor of Chemistry in University College, Nottingham; Section G (Engineering), Mr. Dugald Clerk, M.Inst. C.E.

MISCELLANEOUS CITY NOTES

BUENOS AYRES GRAND NATIONAL TRAMWAYS.—An interim dividend of 2s. 6d. per share, less income tax, has been declared upon the 5 per cent. cumulative preference shares.

MONTREAL LIGHT, HEAT & POWER CO.—Subscriptions are being invited for $400,000 4½ per cent. first mortgage bonds. The bonds are for $1,000 each, and are payable, principal and interest, at the Bank of Montreal, London. The list closes to-morrow.

OXFORD ELECTRIC CO.—The directors recommend a dividend of 7 per cent. for the year 1907, including the interim dividend of 2½ per cent. paid in September.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The transfer books and register of members of this company will be closed from the 15th to the 28th February (both days inclusive).

S. P. SYNDICATE.—A prospectus has been issued of this company, inviting subscriptions for £6,500 in £1 shares. We give some particulars of the objects of this company on another page. The list closes on February 21st.

TELEGRAPH CONSTRUCTION & MAINTENANCE CO.—A dividend of 10 per cent., together with a bonus of 2½ per cent., in addition to the 5 per cent. (already paid), making 7½ per cent. for the year 1907, has been declared.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—A statement has been issued to the effect that an Advisory Committee, consisting of Mr. Edwin Waterhouse (Chairman), Mr. Spencer Phillips, Mr. Marlborough Pryor, Mr. Thomas Skinner, and Mr. John Akroyd, with Mr. Lynden Macassey as secretary, has been formed for the purpose of considering, in conjunction with the board and Messrs. Speyer, a scheme dealing with the profit-sharing secured notes and the financial requirements of the Underground Electric Railways Co. of London (Ltd.). A similar committee has been formed in Amsterdam, and it is further understood that one is being formed in New York. The board hope to be able to publish the scheme at an early date.

NEW PUBLICATIONS

"Proceedings of the American Institute of Electrical Engineers," February. (New York: The Instutution.) 50 cents.

"Science Abstracts," Section A Physics, Section B Electrical Engineering, January, and Index. (London: E. & F. N. Spon, Ltd.) 1s. 6d.

Leeds Local Section of the Institution of Electrical Engineers.—A very successful smoking concert was held by the section on Thursday last at the Hotel Metropole, Leeds. Mr. G. D. Aspinall Parr was in the chair, and an excellent programme of music had been arranged by Mr. T. Harding Churton.

Breach of Contract for Electricity Supply.—On Tuesday, in the King's Bench Division of the High Court, Mr. Justice Ridley delivered judgment on the legal point as to defendants' liability, raised in the case of Bourne and Another v. the Marylebone Borough Council (see ELECTRICAL ENGINEERING, February 6th, 1908, page 204). His lordship said that it was not for a breach of the statutory obligations that the action was brought, but for breach of the alleged contract. It was for not performing a contract for which due consideration was given, namely, that current at 240 volts should be supplied by the defendants to the plaintiffs by the first week of September, 1905, and for not performing another contract for providing current at 200 volts. On the finding of the jury, he held that the plaintiffs were entitled to judgment for the agreed sum of £500 and costs.

Telegraph Traffic.—For the third time this year we have to announce the interruption of the cable between Trinidad and Demerara, in consequence of which the latter colony is entirely cut off from telegraphic communication. The Indo-European land lines were down between Kertch and Odessa on the 6th inst., and were repaired on the same day. Another interruption occurred between Berlin and Warsaw on February 7th, and this was put right on the 8th inst. The Hanekin route ceased working, but was restored on the 10th inst. The Fao and El Arich routes have also again given out. On the 10th of this month, we learned that the cable between Tangier and Cadiz and between Pathurst and Bessao were not working. Owing to the revolutionary conditions in Hayti, telegraphic messages for towns inland cannot be accepted. Owing to the unfortunate occurrences in Portugal, the Telegraph Conference, which was to have been held in April, has been postponed till the 1st of May, but the exact date of assembly will be notified later. The message to Congress of the President of the United States contained a recommendation to prohibit the use of the mail, telegraph, and telephone service for gambling operations in stocks. Captain Larnder is now in command of the cable-ship *Mackay-Bennett*, belonging to the Commercial Cable Company. The late commander was Captain Schenk. The cable steamer *Henry Holmes*, belonging to the West India and Panama Telegraph Company, was last heard of at Jamaica. Telegraph offices have been opened at Brookin, Surrey; Canvey Island; Forncett St. Mary, Norwich; Alexandra Park, Glasgow; Hundred House, Brecon; Medomsley, Newcastle-on-Tyne; Levenhall, Musselburgh; St. Tudy, Bodmin; East Harnham, Salisbury; and at Yeolmbridge, Launceston.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £61 10s. to £62 10s. per ton (last week £63 to £63 10s. per ton).

CABLE MAKERS' ASSOCIATION.—Messrs. Charles Mackintosh & Co., Ltd., 1 and 3 Golden Lane, London, E.C., inform us that they are now members of the Cable Makers' Association.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—At the Court House, Wandsworth, last week, William Robert Pether, consulting engineer, 94 Fernlea Road, Balham, London, and 124 Chancery Lane, W.C., was up for public examination. The unsecured liabilities were stated at £468, and there were said to be no assets. He ascribed his failure to being unable to realise money on shares which he held in the X Electric Accumulators Co., Ltd., which company was promoted by a Mr. Oppermann. The company had not been a success. It had not paid a dividend, and the shares were not of marketable value.

The Electric Installation Co. is to be wound up voluntarily. The liquidator is Mr. J. Mather, 8 King Street, Manchester.

Notice is given of an intended dividend in the bankruptcy of Albert Dickinson, electrical engineer, 3 Barden Grove, Armley, Leeds. The last day for receiving proofs is February 28th, and the trustee is Mr. J. Bowling, 24 Bond Street, Leeds.

APPOINTMENTS AND PERSONAL NOTES

A discussion took place in the Cheltenham Town Council upon the recommendation that the salary of the City Electrical Engineer, Mr. W. J. Bache, be increased from £400 to £500 per annum. After several amendments had been moved the question was referred back to the committee.

At the annual dinner of the staff and employees of the Swansea Improvements and Tramways Co., last week, the General Manager, Mr. David James, was presented with a gold watch by the employees.

TENDERS INVITED.

CORPORATION OF DUNDEE.

ELECTRICITY SUPPLY DEPARTMENT.

E.H.T. 3-Phase and Direct Current Switchboards, Sub-Station Converting Machinery and Apparatus.

New Carolina Port Main Generating Station and Sub-Stations.

THE ELECTRICITY COMMITTEE OF THE CORPORATION OF DUNDEE are prepared to receive Tenders for the SUPPLY and ERECTION complete of the following:—

Section (a)—E.H.T. and D.C. Switchboards, for Carolina Port Main Generating Station.
,, (b)—Converting Machinery and Apparatus for Carolina Port Main Generating Station.
,, (c)—E.H.T. Switchboard for Dudhope Sub-Station.
,, (d)—Converting Machinery for Dudhope Sub-Station.
,, (e)—E.H.T. and D.C. Switchboards for Clepington Sub-Station.
,, (f)—Converting Machinery for Clepington Sub-Station.
,, (g)—E.H.T. and L.T. Switchboards for Lochee Sub-Station.
,, (h)—Converting Machinery for Lochee Sub-Station.

Copy of General Conditions, Specification, and Forms of Tender, together with drawings, may be had on application to the undersigned on deposit of a sum of Three Guineas (£3 3s.) and a deposit of One Guinea (£1 1s.) for each extra copy if required. Deposit fees will be returned only on receipt of complete specifications and drawings sent.

Only Tenderers quoting for complete sections will be considered.

Tenders endorsed, "Tenders for E.H.T. and L.T. Switchgear and Converting Machinery" to be forwarded to W. H. Blyth Martin, Esq., Clerk to the Corporation, City Chambers, Dundee, and to be in his hands by first post, Monday, 2nd March, 1908.

The Corporation do not bind themselves to accept the lowest or any tender.

H. RICHARDSON, M.I.E.E.,
Engineer-in-Chief.

Corporation Electricity Department,
Dudhope Crescent Road,
Dundee.

SUMMARY

REVIEWS of the following books appear in this issue: "Steam and Exhaust Pipes," by R. McGregor; "The New Matriculation Light," by R. W. Stewart; "The Metric and British Systems of Weights, Measures, and Coinage," by F. Mollwo Perkin; "Notes on the Use of Electricity for the Garrison Artillery," by J. R. J. Jocelyn; "Electric Light and Power," by E. E. Brooks and W. H. N. James; "Electric Wiring and Fitting for Plumbers and Gas-fitters," by S. F. Walker; "The B. I. Handbook"; "English Prices and French Equivalents," by H. P. McCartney. (Page 259.)

AN electrically-driven scene-shifting equipment has been installed recently at Wyndham's Theatre. A single motor is employed, which drives a long shaft at a constant speed. The separate winding drums by which the cloths, &c., are raised and lowered derive their motion from this shaft by an arrangement of clutches and gearing. (Page 261.)

AN article by a contributor describes a system which he recommends for house wiring departments of small central stations, dealing particularly with the way in which the work should be booked and the various repairs entered up. (Page 262.)

A NEW combined refuse destructor and electricity works in Greenock embodies some new features in destructor design, among which is a device for automatically opening and closing the charging door of the destructor furnace—so that the charging is accomplished without manual labour and with an absence of dust—and a well-designed system for supplying the furnaces with forced draught and ventilating the clinkering floor. The new works contains coal-fed boilers as well as destructor boilers; at present the plant capacity is 1,500 kw., and the station, which will eventually supply the greater part of the load at Greenock, is capable of considerable extension. (Page 263.)

A SMALL gas-engine-driven generating station has been opened recently at the "First Garden City," Letchworth. (Page 267.)

AN article by Mr. C. C. MONCKTON calls attention to the need for the accurate standardisation of wave-lengths in view of the impending international control of wireless telegraphy, and describes a method for their measurement. (Page 268.)

A POWER installation in the south of Sweden, remarkable for the special construction of the supports for a long span in the transmission line, is described. (Page 269.)

A LONG and somewhat detailed appendix dealing with the electrical industry in Spain is attached to a Consular Report, just issued, upon the trade and com-

Digitized by Google

merce of Spain during 1906. Attention is drawn to the absence of any noteworthy British enterprise in the application of electricity in Spain, the whole of the business being practically in the hands of Germany, Switzerland, France, United States, and Belgium. A strong appeal is made to British financiers and investors to give greater attention to the still numerous opportunities afforded for the remunerative investment of capital, and a suggestion is made that the Institution of Electrical Engineers or some representative combination of British manufacturers should take steps to have an investigation made by someone acquainted with Spain, into the great openings which that country undoubtedly affords. (Page 270.)

MR. J. S. PECK'S Paper on Protective Devices for High-tension Circuits, on which reports of the discussions in London and at Manchester have already been given, was further discussed at the Dublin Local Section of the Institution of Electrical Engineers last Thursday, when experiences in dealing with voltage surgings in lines of various descriptions were given by central station, tramway, and telephone engineers. One of the speakers described a special form of Wurts arrester for continuous-current circuits. (Page 271.)

IN a further discussion, in Glasgow, of Mr. J. F. C. SNELL'S Paper on the cost of power supply for industrial purposes, several additional figures of the costs of private plants were quoted. Mr. STOTHERT stated that the cost of electric power at Messrs. Babcock & Wilcox's Renfrew works was 0·45d. per unit, including an allowance for depreciation. Mr. NEWINGTON gave a case in which the cost of running a suction-gas plant came to 1·13d. per unit (including all capital charges, but not rent) as against 1·2d. charged by the Corporation previously. Mr. J. A. ROBERTSON pointed out that the total cost of electric energy in a shipyard, whether the energy was bought or from a private plant, came to but a small percentage of the wages bill; in a particular case in Greenock the wages came to £135,000 annually and the power only £4,000. Mr. Snell, in the course of his reply, said that since writing his Paper more than a year ago, the price of oil fuel had risen from 42s. 6d. to 82s. 6d. per ton. (Page 272.)

A NEW petrol-electric railway car is being taken into use on the Delaware and Hudson Railway in America. An eight-cylinder petrol engine drives a specially constructed interpole generator, which supplies current to two traction motors mounted one on each truck. A feature of the control is the variation of the generator voltage. (Page 273.)

THE accounts of the Central Electric Supply Co. for 1907 show a surplus of £5,042; those of the Kensington & Knightsbridge Electric Lighting Co., £9,854; the St. James's & Pall Mall Co. has a surplus of £28,375; the London Electric Supply Corporation, £34,613; the Notting Hill Electric Lighting Co., £11,000; and the Westminster Electric Supply Corporation, £28,313. (Page 274.)

A PAPER was read by Mr. B. HOPPS last Thursday, before the Rugby Engineering Society, on the London motor omnibus problem, in which attention was drawn to the petrol-electric system designed by the British Thomson-Houston Co. (Page 275.)

A LARGE electric lift has been constructed in New York for taking cars in and out of the new tunnels under the Hudson River. (Page 276.)

AN article in an American contemporary by BELA VALATIN compares the performance of a certain American single-phase 15-cycle experimental locomotive with that of the 3-phase locomotives of the Italian State Railways. (Page 277.)

THE annual dinner of the General Electric Co. was held on Saturday last. (Page 278.)

A PAPER read by Mr. E. F. ALEXANDERSON recently before the American Institute of Electrical Engineers described a new form of single-phase traction motor, to which the name of series-repulsion motor was given. The windings resemble those of a series motor. When starting, the armature is short-circuited, and the full secondary voltage of the transformer is impressed upon the "inducing" and exciting stator windings, but when running part of the power is introduced in the stator, and part in the rotor. (Page 279.)

A SHORT article reviews the controversy occasioned by the action of the Board of Trade in suggesting that the official Board of Trade audit of electricity supply companies' accounts should be dispensed with. (Page 281.)

A VERY complete equipment for measuring the horse-power at the road wheels of automobiles has been installed by the Automobile Club of America. (Page 282.)

Under ELECTROCHEMISTRY and ELECTROMETALLURGY, we abstract two articles which show how the advent of electrical energy made the artificial production of diamonds possible, and incidentally helped to throw light upon the manner in which they are formed in nature. A multi-voltage dynamo for electroplating purposes, with two commutators, each connected with half of a double winding on the armature, is described. Each set of brushes may be connected with separate plating tanks, which can thus be operated independently. To increase the voltage, the two sets run in series. Reference is also made to the reduction of nitrates with copper electrodes, to an improvement in the electrolyte of the alkaline accumulator, and to the dividend announcement of the Electrochemische Werke of Berlin. (Page 283.)

Under ELECTRICAL SCIENCE, in the British and American Section, are notes on some new experimental data regarding positive electrons in atoms, and on some formulæ for self-inductance. In the Papers abstracted in the Continental Section, CLERC and MINET describe a new electric furnace, CATHIARD shows how to use a flame as a rectifier, and DUFOUR brings forward some more magneto-optic anomalies suggestive of positive electrons. (Page 284.)

AS the result of a decision in the courts last week, the purchase by the Corporation of the horse tramways in Oxford will take place upon "old iron" terms, and not upon the basis of a going concern. The arbitration proceedings, which were interrupted on the first day for this point to be determined, will shortly be resumed. (Page 284.)

The new patent specifications published last Thursday by the Patent Office include two relating to filaments for electric lamps by the BRITISH THOMSON-HOUSTON Co., and another by the same firm describes a new type of overload cut-out. GANZ & Co. have patented a device for the pressure regulation of alternating-current generators, and Mr. MILES WALKER has a new method of reducing the voltage between adjacent commutator bars of armatures of high-speed machines. (Page 285.)

THE Bournemouth Corporation have rejected the auditor's recommendation that a reserve fund should be established in connection with the tramways. Arrangements for permanent tramway intercommunication between Bradford and Leeds, using Mr. Spencer's extensible gauge truck, are now under consideration. The accounts of the Dublin Corporation Electricity Department for the year ended March 31st, 1907, show a debit balance of £1,720, after providing for £23,700 repayment of loans and interest. The Ealing Corporation has instructed the Borough Surveyor and Electrical Engineer to submit an estimate of the cost of constructing a short length of tramway upon the Dolter surface contact system. The Finchley Corporation has rejected a recommendation instructing the Finance

Digitized by Google

Committee to inquire what the annual amount would be for a reserve fund in connection with the electricity undertaking. The accounts of the Liverpool Corporation lighting and tramways undertakings show a net surplus of £27,500 and £27,793 respectively, after meeting capital charges, both of which amounts it is proposed to transfer to the Borough fund. At the Court of Common Council last week it was stated that although there are about 9,000 electric lighting street boxes in the City of London, only three small accidents have occurred in connection with them during the past three years. The arrangements at Edinburgh in connection with the use of sewage water for condensing purposes at the McDonald road power station are now practically complete. The Sunderland Corporation have discontinued the supply of electrical energy to the works of Sir J. Laing & Sons, in consequence of there being a debt of £2,300 for current. (Pages 287-289.)

The date for receiving tenders for cable, &c., in connection with the supply of electrical energy to the Avonmouth Dock district by the Bristol Corporation has been extended to February 27th. The following Corporations intend making applications to the Local Government Board for loans for electricity works extensions:—Burslem, Dartford, Stoke-on-Trent, and Wigan; the Hull Corporation invite tenders for three 500-kw., 2,250-volt, continuous-current generators; the Handsworth Urban District Council require a 350-kw. generating set; and the Manchester Corporation require four water-tube boilers and accessories for the Stuart Street generating station. (Page 289.)

The Hastings and District Tramways Company's report shows a balance of £13,767 available for distribution. At the meeting on Monday the Chairman stated that although very little was known of the Dolter surface contact system when the company adopted it, the line was now working in such a manner as to lead the directors to hope for fairly good results. The net profit of the Imperial Tramways Company in 1907 amounted to £26,125; the Lanarkshire Tramways show a sum of £15,252 available for distribution; the Newcastle & District Electric Lighting Company have made a net profit of £19,922; and the Bristol Tramways and Carriage Co. have a net revenue of £85,347. An adjourned meeting of the debenture holders of the Brush Electrical Engineering Co. was held on Friday, when the resolution to modify the Company's debenture stock was declared to be lost. A poll is to be taken on the 27th inst. At the meeting of the Metropolitan District Railway Co. last week, Sir George Gibb stated that the directors' proposals with regard to capital were the only ones which would put the company upon a sound basis again. In order to dispel any idea that the working costs on the District Railway were extravagant or excessive, he gave some figures of the working expenses on other London tube railways. At a special general meeting of the South Wales Electric Power Distribution Co. last week, the Bill now before Parliament dealing with the transfer of the company's stations, &c., was approved. At a special meeting of Edmundson's Electricity Corporation, a special committee of shareholders appointed last July was presented; the acceptance of the resignation of the present Board, and the issue of £250,000 prior lien debentures is recommended; the co-operation of Mr. J. S. Highfield and Mr. Stanley Beeton is also advised. A circular has been issued by Messrs. Bruce Peebles & Co. informing the shareholders that it has become necessary to call a meeting for the purpose of putting the company into voluntary liquidation with a view to reconstruction. (Pages 290-294.)

Sir John Gavey, C.B., has been appointed Consulting Engineer to the Post Office. The salary of Mr. A. L. C. Fell, Chief Officer of the L.C.C. tramways, has been raised from £1,500 to £1,750. (Page 292.)

The announcement that Messrs. Bruce Peebles and Co., Ltd., have decided to go into voluntary liquidation has probably given more occasion for surprise to the shareholders of that company than to the electrical engineering public generally. The reports and accounts of the company for the year 1906 showed a net profit, available for distribution, of nearly £46,000; 6 per cent. dividend was paid on both the preference and ordinary shares, and sums were also carried to a special preference shareholders' reserve fund, and the general reserve account, which brought these funds to totals of £11,556 and £27,000, respectively. The previous year's dividends had been 6½ per cent. on both classes of shares, but this slight falling off could hardly have been taken as presaging a disaster in a year's time. A closer examination of the position of the company, however, showed that the amounts outstanding in unpaid accounts on both sides of the balance sheet were extremely large, and it was clear that there was some lack of working capital, as the issue of £100,000 in debentures was decided upon. For this purpose the borrowing powers of the company were increased to £200,000, and as the share capital was £300,000, the total would have represented half a million. It is now evident that further working capital must have been needed very urgently, for, as a consequence of their inability to make the further issue of debentures owing to the stringency of the money market, the company has been obliged to go into voluntary liquidation. It has been currently reported for some time, in electrical engineering circles, that a fair proportion of the company's capital was locked up in shares in other companies, received in part payment for contracts, and the admission is now made that it is not possible to realise advantageously the securities in which the company is interested. At a meeting of the company on Monday the shareholders will be asked to appoint Mr. A. W. Tait (one of the directors) and Mr. J. A. Robertson Durham (the nominee of the creditors) as joint liquidators. The directors have done wisely in selecting Mr. Tait for this arduous task, as it was largely due to his energies as one of the liquidators of Ferranti, Ltd., that this old firm was satisfactorily reconstructed a few years ago. Doubtless, Messrs. Bruce Peebles will continue for many years to manufacture the small motors and the La Cour motor-converters with which they have been so successful, and will show more restraint in the future in entering on the more ambitious form of contracts to which apparently their present unfortunate position is to no small extent attributable.

Combined refuse destructors and electricity works had at one time fallen into disrepute with electrical engineers, chiefly on account of the dust arising from the refuse itself, and from the products of combustion as they were raked out of the furnace. Another criticism levelled against destructor stations was the unavoidable variations in the calorific value of the refuse, and the uncertainty of the steam supply in consequence. Both of these objections are to a large extent overcome in the dust destructor station at Greenock described in this issue. It represents a great improvement in destructor design. Each cartload of refuse is emptied into a charging tub as it comes in, and this can be raised by an electric crane, and either emptied directly into the furnace, or kept for a time on the charging

Digitized by Google

platform. The action of charging takes less than a minute, and practically no dust is evolved. On the clinkering floor a certain amount of dust is unavoidable, but this is at some distance from the engine-room. From the chimney itself there must also be some dust, but by ensuring proper combustion this can also be reduced to a minimum, and the system of forced draught employed in the Greenock destructor should assist in this direction. The use of these forced draught fans should also be of help in endeavouring to keep the steam pressure regular. At Greenock, as the steam which the destructor will furnish will ultimately be only a small proportion of the whole steam required, it should be possible to burn the refuse as it comes in, and to keep the destructor always working at an even load throughout, leaving the coal-fired boilers to take the peaks. When used in this way, if the new plant comes up to anticipation, the question of economy is easily settled. It is admitted that a destructor is the best way to dispose of town refuse, so that the question to be decided is whether the interest and sinking fund on the cost of fitting boilers to the destructor plant, to which must be added a percentage for depreciation, and the cost of maintenance, is less than the value of the steam delivered to the engines of the electric power plant. If so, the combined plant at Greenock should prove a success. The results of the first year's working will be awaited with interest.

WE regret to hear that Mr. Hall-Edwards, Surgeon-Radiographer to the Birmingham General Hospital, has suffered amputation of an arm in consequence of serious X-ray burns. This deplorable occurrence serves to draw attention once more to the dangers which menace all those who, in the practice of their profession, have to spend part of each day in the neighbourhood of X-ray tubes in action. It is necessary to distinguish between the acute inflammation of the skin which can be produced by a single excessive dose of the rays, and the chronic, slowly developing condition which results from often-repeated exposure to small doses. It is the latter which is the special bane of X-ray workers; the former is nowadays almost unheard of, as a result of a better appreciation of the magnitude of dose at which danger begins to threaten. The pain and suffering experienced by the subjects of chronic X-ray dermatitis are very serious; the fingers become cracked and ulcerated, and no ointment or other application seems to have the least good effect in healing these sores. Subsequently the tissues of the fingers waste, the knuckles become stiff, and the hands are rendered useless. In bad cases the sufferer cannot wash or dress himself, and becomes almost helpless, while the intense pains continue night and day. Unfortunately, there are many medical men all over the world who have suffered and are suffering more or less seriously from the results of exposure to X-rays. At the Congress of Physical Therapeutics, held at Liège three years ago, we were much impressed at seeing that there was hardly a member of the X-ray section of the Congress who did not carry scars or wounds produced by chronic exposure to X-rays. Since these dangers have been more fully realised, precautions of a systematic kind have been adopted, and have tended to reduce the dangers very considerably. Gloves and aprons of dense material, lead or glass screens for the tubes have now come into general use, but there are many instances of injury to the hands which developed in the earlier days of X-rays, and now are beyond repair.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, FEBRUARY 20TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly, W. Among the Papers down for reading is the following:—"Effects of Self-Induction in an Iron Cylinder when traversed by Alternating Currents," by Prof. Ernest Wilson.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, S.W. Papers to be read:—(1) "Electrical Power in Railway Goods Warehouses," by H. Henderson. (2) "Electric Power in Docks," by C. E. Taylor.

FRIDAY, FEBRUARY 21ST.

Electro-Harmonic Society.

8 p.m. Concert (ladies' night) at the Bechstein Hall, Wigmore Street, W.

Institution of Mechanical Engineers.

8 p.m. Annual General Meeting at Storey's Gate, St. James's Park, London. The following Paper will also be read and discussed:—"Tests of a Live Steam Feed Water Heater," by Prof. John Goodman.

Royal Institution.

9 p.m. Evening Discourse by Sir Oliver Lodge on "The Ether of Space."

SATURDAY, FEBRUARY 22ND.

Birmingham and District Electric Club.

7 p.m. Meeting at the Municipal Technical School, Suffolk Street, Birmingham. Paper to be read:—"The Electrodeposition of Silver," by T. J. Baker.

Central Technical College Old Students' Association.

7.15 p.m. Annual General Meeting and Dinner at the Trocadero Restaurant, Piccadilly, W.

MONDAY, FEBRUARY 24TH.

Institution of Electrical Engineers: Students' Section.

7 for 7.15 p.m. Annual Dinner at the Holborn Restaurant, London.

Institution of Electrical Engineers: Newcastle Local Section.

8 p.m. General Meeting at the Armstrong College, Newcastle-on-Tyne. Paper to be read:—"Electric Power in Docks," by C. E. Taylor.

Liverpool Chamber of Commerce.

8 p.m. Address on Wireless Telegraphy by Signor G. Marconi.

TUESDAY, FEBRUARY 25TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology, Whitworth Street. There will be a discussion in conjunction with the Manchester and District Junior Gas Association upon "Gas v. Electricity for Illuminating Purposes."

WEDNESDAY, FEBRUARY 26TH.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. Meeting at 92 Victoria Street, Westminster. Paper to be read:—"Wattmeters and their Connections," by J. C. Connan.

FRIDAY, FEBRUARY 28TH.

Physical Society.

5 p.m. Meeting at the Royal College of Science, Imperial Institute Road, South Kensington. Paper to be read:—"Contact Potential Differences Determined by means of Null Solutions." By S. W. J. Smith and H. Moss.

SATURDAY, FEBRUARY 29TH.

Institution of Electrical Engineers: Students' Section.

10 a.m. Visit to the Brimsdown power station of the North Metropolitan Electric Power Co.

Destruction by Fire of the Eiffel Tower Wireless Telegraph Station.—On Tuesday afternoon the shed containing the wireless telegraph apparatus at the foot of the Eiffel Tower was destroyed by fire. It is stated that the outbreak was due to a short circuit which occurred during some experiments that were in progress. The tower itself and the aerial are uninjured, but as the apparatus has been destroyed, communication with Casa Blanca will be interrupted for some time. The building was a temporary one, and a decision had already been arrived at to replace it by a permanent underground station at the base of the tower.

REVIEWS OF BOOKS

Steam and Exhaust Pipes. By R. McGregor. 22 pp. 9¼ in. × 12 in. 39 illustrations. (London: *The Electrical Times.*) 1s. 6d.

Modern power-stations, although of good design and construction as regards their boilers and engines, are frequently defective as to the steam distribution, and the author of this book brings before his readers some typical examples of what he considers should be the true methods to be adopted when arranging the steam-pipe system of generating stations. In the preliminary chapters, the drainage of the steam range is fully considered, and the best methods of ensuring freedom from water in both the steam piping and engine cylinders. Superheated steam has a most important bearing on the drainage requirements of a steam range, as with a dry superheated steam there is not so much danger of getting water in the pipework, but still efficient means must be taken to provide for what water there does happen to be, and this is obtained by the placing of steam traps in front of every stop-valve on the range, and also the provision of separators at convenient intervals. Steam piping subjected to great temperatures will elongate so much as ⅜ in. in 10 ft., and due provision for this must be made in the range by means of expansion stuffing boxes in some cases, or by the more modern practice of placing bends at some suitable position. When vibration occurs in a pipe range, it may be due to instability of the engine and cylinders, or to the pulsating flow of the steam causing a surging action to take place; so sharp bends should be avoided, and the steam-pipes arranged so as to get as straight a flow as possible.

With the general arrangement of the pipework, the author deals very fully. He does not approve of the practice of double and ring steam mains, and advocates that when the boiler-house runs parallel to the engine-room, the steam range can act as an equaliser, and its dimensions be kept down; but the steam range must be 15 to 20 per cent. larger in diameter than the maximum engine or boiler branch. "Minor" details of design—the subject of lagging, radiation losses, scale in the pipes, isolating valves, and general arrangement of drains and blow-down pipes, and the feed-water service—are dealt with, but some of these details are so important that it would have been better if more emphasis had been given to them. The general arrangements advocated in the book are extremely well advised, and, if adopted by station engineers, there should be far fewer blown-out joints and accidents than at present. The writer has given prominence to features which are frequently overlooked in everyday work, and are not usually referred to in text-books. In practical work, arrangements are generally a matter of compromise, and the best method is that which contains the fewest imperfections, but certain vital points admit of only one treatment, and the author endeavours to point these out. The low price of the book is in its favour.

The New Matriculation Light. By R. W. Stewart. 282 pp. 7 in. by 5 in. (London: W. B. Clive.) 2s. 6d.

This is a very good introductory text-book of light. It contains the ordinary matter found in all the elementary text-books on the same subject—mirrors, prisms, lenses, simple optical instruments, photometry, and dispersion—but the matter is not treated in quite the ordinary way. In fact, an attempt is made to blend practical work with the theoretical, and to this end simple experiments illustrative of the text are suggested to the student and fully described. These experiments require nothing more than spectacle lenses, bits of looking-glass, and pins, and if the home student will only do them, as well as read about them, they will make preparation for the matriculation examination rather less of a cram than it usually is. Quite apart from examination preparation, the clear diagrams of the rays through optical instruments, and the pages on colour and dispersion, will be helpful to those requiring for any purpose just a little knowledge of light.

The Metric and British Systems of Weights, Measures, and Coinage. By Dr. F. Mollwo Perkin. 83 pp. 5½ in. by 8½ in. 17 illustrations. (London: Whittaker and Co.) 1s. 6d.

As Dr. Perkin says in his preface, this exposition of the metric system is the outcome of experience in teaching the use of that system of units, and is intended to be placed in the hands of students of chemistry, physics, engineering, or general elementary science. Whatever be our views upon the practicability of an immediate adoption of the metre and the gramme in this country, to the exclusion of existing cumbrous methods, it is undeniably essential that every student should acquire a good working knowledge of the system. It would probably be much easier to teach children to think in metric units before they had acquired a familiarity with British measures, but as things are there is ample demand for a book such as this before us, intended to introduce the conception of these units at a later stage. The treatment of the subject is clear, and, in addition to tables, some curves (or rather straight lines) for conversion of British and metric quantities are given which should prove of use. The book, however, contains more than this, as chapters are also included on methods of finding specific gravities, which, in addition to familiarising the student with some of the more elementary methods of making measurements of the quantities he has been dealing with, presents excellent examples to enable him to realise the relations of the different kinds of units. Although not, strictly speaking, coming under the head of the metric system, information is also given as to the relation of the three thermometric scales in common use, and the conversion of English money into foreign decimal currencies, and here again useful diagrams are given. An excellent series of tables involving even the most out-of-way units is contained in an appendix. We note here that "knot" is used as synonymous with the nautical mile, although we believe this word, strictly speaking, signifies the unit of speed for ships, and the spelling "naut" should be employed as an abbreviation indicating the unit of distance. The units adopted by the United States Bureau of Standards are also given with their metric equivalents. We do not often see these equivalents in handbooks, and such literature among the usual conversion tables, and we do not think it is very generally realised that the British and American units are slightly different. The equivalent of the two kinds of inches, for example, are respectively 25·39954113 mm. and 25·4001 mm. The different thermal units are also explained, but, naturally, electrical quantities do not come within the scope of the work.

Notes on the Use of Electricity for the Garrison Artillery. By Col. J. R. J. Jocelyn. 227 pp. 7¼ in × 4⅜ in. 160 illustrations. (London: Wyman & Sons). 1s. 6d.

This book is designed for the use of regimental officers and non-commissioned officers whose duties may bring them in contact with electrical appliances. It commences with several sections on elementary principles, which are then followed by practical informa-

Digitized by Google

tion as to the general uses to which electricity is adapted to the artillery, descriptions of the gun-plug, firing-key, and the Webb charge and discharge key, which are all used in connection with guns fired by electricity. The different kinds of batteries, electric tubes, and firing gear, searchlight and incandescent lights, and telephone receivers are also dealt with. The book is well written, and comprises a deal of matter which should be useful for the purposes for which it is intended.

Electric Light and Power. By E. E. Brooks and W. H. N. James. 372 pp. 7½ ins. by 4¾ ins. 230 illustrations and 17 plates. (London: Methuen & Co.) 4s. 6d.

THIS book is primarily intended for students of electrical engineering. The commencing chapters deal with magnetic lines of force, and the student is shown in a simple manner the effect of magnetism and its relation to electric currents. A number of experiments are described, and illustrations are given to enable the student to obtain a clear impression of what may be called the first steps in theoretical electrical knowledge. Following the subject of magnetism, the authors deal with the electric circuit, and show how different electrical measuring instruments act under the influence of the current, and define the different terms used in electrical science. In Chapter 4 the subject of resistance is considered, and its measurement and effect are discussed. The subject of Chapter 6 is induction coils and transformers, and their general construction and action are clearly defined. The authors then proceed to deal with continuous current generators. They do not in this chapter introduce the unnecessary difficulties which characterise the terminology of many writers, but keep prominent the two distinct ideas of magnetisng force and magnetic field. These chapters show the action of the brushes and their relative positions on the commutator, in relation to the load and voltage of the machine. The subject of lighting circuits, with all their different methods of connection and requirements, is fully dealt with, together with the construction of different kinds of incandescent and arc lamps. Chapter 11 deals with the construction of different kinds of measuring instruments and methods of testing circuits, whilst the concluding chapters consider primary cells and accumulators, including the construction of their electrodes, method of charging, and general instructions for their testing and maintenance. This work is founded on the actual experiences of the authors, gained by some years of technical instruction, and clearly expresses in a manner which is easily grasped the more simple facts connected with electrical phenomena and their applications.

Electric Wiring and Fitting for Plumbers and Gasfitters. By Sydney F. Walker. 157 pp. 7¼ in. by 5¾ in. 94 illustrations. (London: Scott, Greenwood & Son.) 5s.

IN the unlikely event of our employing a plumber or gasfitter for electric wiring and fitting, we should give the preference to one who had not read Mr. Walker's book.

The B.I. Hand-book. 568 pp. 7¼ in. by 4¾ in. (Prescot: British Insulated and Helsby Cables, Ltd.) 7s. 6d.

IN this new publication a great deal of general information is included which is likely to be of use to the electrical engineer, as well as a description of the principal manufactures of British Insulated and Helsby Cables, Ltd. Much of the general information is, of course, already public property, and is simply repeated in a convenient form, but a quantity of hitherto unpublished matter of a technical nature is also given. About 100 pages are devoted to particulars and specifications of cables and wires of all sorts, and here the details are much fuller than in the average cable manufacturer's catalogue. A number of forms of feeder pillar fuse-boxes, &c., are illustrated and described, including the "Prescot" pillar (described in ELECTRICAL ENGINEERING, Vol. I., p. 519). Succeeding sections deal with tramway poles and overhead material, noiseless paper pinions, electric welders (see ELECTRICAL ENGINEERING, Vol. I., p. 791), annealing furnaces, and hydraulic pumps. Particulars are also given of the Mordey-Fricker electrolytic prepayment meter, of which the company are the manufacturers, a considerable number of patterns of insulators for overhead lines are illustrated. Details are also given of all kinds of material and tools for overhead line construction. Other articles dealt with are mine exploders, golf balls, and telephone and telegraph apparatus. The second portion of the book commences with data required for the calculation of transmission systems, including well-arranged tables, formulæ, and graphic methods for ascertaining losses. A very full description is given of the Merz-Price patent protective gear, and the tables of the Engineering Standards Committee for insulation of cables are reproduced, together with very complete tables of copper conductor and wire gauges. A good deal of information regarding overhead lines and poles is given which is not found in the ordinary pocket-book. A few pages are devoted to suggestions on the best method of arranging apparatus and wiring a telephone exchange, and a digest of the new Patent Act (reprinted from ELECTRICAL ENGINEERING, September 19th, 1907), is given. The Institution wiring rules are also reprinted, and all the Board of Trade and Home Office Regulations affecting electrical engineering are given. A good deal is included that is not in the ordinary pocket-book, while much of the useless matter which is inserted into most pocket-books from a mistaken idea of completeness has been wisely omitted. The printing and binding are excellent, and a well-arranged index enhances the utility of the publication.

English Prices with French Equivalents. By H. P. McCartney. 95 pp. 4 ins. by 3 ins. (London: E. & F. N. Spon.) 1s.

THIS pocket-book consists entirely of a series of tables giving the equivalents in francs per 100 kilos of prices per lb. in English money. The rates per lb. advance by sixteenths of a penny up to one shilling, by farthings up to five shillings, by halfpennies up to ten shillings, and by pence up to one pound. Another column gives corresponding rates in £ s. d. per ton, and the equivalents in francs (gold) per 100 kilos are given in separate columns for seven different rates of exchange, varying from 25 to 25·30 francs per £. The tables should be of use to those preparing quotations for export.

Water Power Schemes in Japan.—According to the *Electrical World*, the first 60,000-volt hydro-electric plant in Japan has just been put into service, after having passed the rigid inspection which is required by the Japanese Government of all electrical installations. Power is obtained by impounding the Ugigawa, a narrow and swift but deep river, such as is often found in the mountainous portions of Japan. The normal rating of the main station, which is 18,000 kw., is furnished by six 3,000-kw., 50-cycle, 6,600-volt water-wheel-driven alternators. The generator voltage is stepped up to the line E.M.F. of 60,000 volts through three banks of three single-phase, water-cooled, 2,000-kw. transformers, at which potential energy is transmitted 25 miles to the Waseda sub-station just outside the city of Tokio. In this main sub-station water-cooled, 1,800-kw. transformers decrease the E.M.F. to 11,000 volts, at which potential energy is transmitted underground through lead-armoured cables to 11 distributing sub-stations situated in various parts of the city. In each of these smaller sub-stations oil-cooled transformers of 250-kw. rating reduce the E.M.F. to 2,000 volts, the line potential of the city circuits.

The Physical Society.—A dinner of the society was held on Tuesday last, the 11th inst., at the Hotel Cecil, London, when the chair was taken by the President, Prof. J. Perry, F.R.S. Those present included Sir David Gill, Sir William Ramsay, Sir William White, Sir J. Denison Pender, Rear-Admiral Sir H. B. Jackson, Sir Arthur W. Rücker, Sir Joseph Swan, Col. R. E. Crompton, Prof. W. G. Adams, Mr. Shelford Bidwell, Dr. C. Chree, Mr. W. Duddell, Prof. Carey Foster, Dr. R. T. Glazebrook, Prof. Reinold, Mr. J. Swinburne, Prof. S. P. Thompson, and Dr. W. Watson. Sir Arthur Rücker, in proposing the toast of "Our Guests," remarked that it was, perhaps, a little difficult to understand why all the guests that evening were not already Fellows of the Society. Sir David Gill, in responding, referred to the foremost position hitherto occupied by Great Britain in the world of physics, as shown by the honoured names of Faraday, Maxwell, Kelvin, and others, whose traditions were now being handed down by such men as Lord Rayleigh and Prof. J. J. Thomson. Sir William Ramsay, in responding to the same toast, dwelt on the relations of physics and chemistry. In response to the President, Prof. E. B. Rosa, of the National Bureau of Standards, Washington, expressed his pleasure at being present. He had been interested in visiting the National Physical Laboratory. At the National Bureau of Standards they were making satisfactory headway, and he hoped that the laboratory would shortly be equal to any national laboratory in the world. Sir William White, in proposing the toast of "The Physical Society," congratulated the Society on accomplishing so much in a comparatively short life. Physics was the basis of many of our societies, but however comprehensive a society might be, new societies sprang up from time to time, and individually we had to be content with a small corner of knowledge. In responding, the President dwelt on the importance of research. At the present day there were many science teachers and many compilers of books who did no research. They were well up in the letter of science, but not in the spirit thereof, with the result that their meetings lacked a most essential quality which could be gained only by actual research. Dr. Chree, the President elect, also responded to this toast, and in conclusion, the President proposed the health of the honorary secretaries, to which Mr. W. R. Cooper and Prof. W. Cassie responded.

SCENE-SHIFTING BY ELECTRICITY

A NEW electrically-driven equipment has recently been installed at Wyndham's Theatre in connection with the scene-shifting arrangements for raising and lowering cloths, sky borders, curtains, &c. The device is an extremely simple one, and it is surprising that the idea was not worked out years ago. For the benefit of the uninitiated it may be explained that, with the exception of wings and heavy pieces of scenery, all scenes are "set" and "struck" from the "flies." The flies consist of two galleries running from the front to the back of the stage about on a level with the top of the proscenium, and it is possible to cross the stage at this giddy height by means of a narrow gangway. Men are prevented from falling off the flies on to the stage by means of a very substantial wooden railing, to which are attached the ropes for dealing with the cloths, &c. These ropes pass over pulleys secured to the gridiron, which, as its name implies, is a cross hatching of beams situated at a distance from the flies rather greater than the flies are above the stage. Hence the cloths are simply drawn straight up well out of sight of the audience. The drawing-up process, however, is not quite such a simple matter as would appear at first sight. Even on a small stage it requires at least three men to raise a cloth, and others have to preserve a sharp look-out to prevent the canvas catching on some projections and thus getting torn. Moreover, owing to the size of ropes which must be employed, there is not room for all the scenes to be set from one side, and it therefore becomes necessary to employ two gangs of men. Wire ropes cannot be employed for hand labour for obvious reasons. Now, it is a serious fact which has to be faced by the manager of a theatre that, so far as stage-hands are concerned, the load factor is an extremely poor one. Actually, in an ordinary three-act play, the stage-hand does not have a good half-hour's work to do, and, as a rule, he is paid half-a-crown for doing it. It is the aim of the new machine to remedy this state of affairs, and appearances are greatly in favour of its success. In the first place, the old hempen ropes will disappear and give place to wire. This, in itself, is an enormous advantage from the fire-risk point of view. Secondly, it will be possible to dispense with the services of at least ten stage-hands in the case of a small theatre like Wyndham's, while this number would be more than trebled at, say, Drury Lane. Further, it expedites the work.

One of the greatest difficulties in the employment of machinery on the stage is that of noise. In the present instance, this difficulty is overcome to such an extent as to make it negligible. Apart from the fact that the machine is practically noiseless, it is seldom employed except when the curtain is down, and, therefore, when the orchestra is playing and the audience talking. Even in the empty theatre the noise is almost inaudible from the front.

The machine itself is situated in the flies on the prompt side, and occupies nearly the entire length. Only a few inches from the floor of the gallery, and supported by iron brackets, is a shaft, 25 feet in length and $1\frac{1}{4}$ inches in diameter, with a key-way cut from end to end. This shaft is rope-driven by a Siemens 4 h.p. electric motor, and carries a number of split bevel gear wheels placed at suitable intervals. Above it and parallel with it is a counter-shaft of the same length and diameter, which can be driven from the main shaft when required through what is termed a "unit." Driving a friction clutch is a raw-hide bevel gear wheel, which engages with a split bevel on the main shaft. The other member of the clutch is fixed to a worm, and is also provided with a spring brake attachment, normally on when the clutch is not engaged. A further raw-hide gearing transmits the power to a sprocket, from which the counter-shaft is driven by a chain. Any number of winding drums can be keyed to this counter-shaft where required.

It is only when it is necessary to raise or lower two or more pieces of scenery at the same time that the counter-shaft is employed. When this is so, the drums are set, and the wire ropes are measured off to the correct length once and for all. It is then simply a matter of raising or lowering, and it will be observed that the relative positions of the pieces are invariable, which is far from being the case with manual labour. For single pieces of scenery a variety of the "unit" is adopted, the only difference being that instead of a chain wheel there is a winding drum, the driving being done, as before, directly from the main shaft. Each unit is provided with a lever which enables the operator to throw it into connection with the main shaft, and therefore wind up; or to disengage it and allow the piece of scenery to drop by its own weight; or, finally, to disengage it and hold it in position by the spring brake. This last-named is the normal condition of affairs. Thus it will be seen that while the machine is running scenery can be raised, lowered, or kept stationary, each winding drum being independent of all the others and of the counter-shaft. There is, of course, no reason why several counter-shafts should not be employed for use in different scenes, although only one has been installed at Wyndham's. Each unit is also provided with an automatic trip device to prevent over-winding. The motor is controlled by a Siemens iron-clad automatic starter, while an emergency switch is provided in close proximity to each unit, by which the motor may be stopped at any time. These emergency switches act upon the no-voltage release of the starter.

With these arrangements it is quite possible for a person standing in the prompt corner to set a scene in a few seconds without the slightest assistance from anyone in the flies. As a matter of fact, however, it has been decided to have the controller and levers in charge of a man in the flies.

In conclusion, we have to thank the management of Wyndham's Theatre for enabling our representative to inspect the machine, and Mr. H. Hipwell, chief engineer to Mr. Frank Curzon, for explaining many of the details. Mr. E. Lytton is the inventor of the apparatus.

Death from Accidental Shock.—An inquest was held at Manchester last Thursday on the death of an apprentice named F. T. Sherring, which occurred at the Westinghouse Works, Trafford Park, on Tuesday of last week. It appears that the deceased was at work in the insulation testing-room at a table a few yards away from the testing apparatus. He was seen to get up from his chair and stand watching the apparatus, when a sudden flash was noticed, and he fell over the barrier with which the high-tension apparatus is surrounded. It is thought that he must have brought his hand in close proximity with a wire forming part of the 25,000-volt circuit. A verdict of accidental death was returned, the jury adding that there ought to be some safeguard, either in the way of barriers or insulating materials, to prevent a recurrence of the accident.

Cadiz-Canaries Cable.—A British consular report states that the question of duplicating the existing Cadiz-Canaries cable has been receiving the attention of the Spanish Government. The existing cable, besides being a single line, is in an unsatisfactory condition, and is liable to constant breakdowns, when recourse has to be had to the somewhat circuitous Brest-Dakar route. Repairs were carried out in 1905 at a cost of £7,000, and it is thought that the cable cannot last more than a few years longer. A cable is now being laid between Palma, Majorca, and Barcelona. The question was recently raised in Congress of laying a cable between Cartagena and Oran, but it was pointed out that there already exists a cable from Almeria to Melilla and Chafarinas, now out of repair, which it would be more practical to extend to Nemours, thus putting Spain in communication with Algeria.

WIRING BUSINESS IN CONJUNCTION WITH THE CENTRAL STATION

AT the present time, in spite of a good deal of controversy on the question, a large number of smaller central stations in this country are undertaking wiring work in conjunction with their electricity supply business. It is not proposed to discuss here whether this policy is wise or otherwise, but to point out that, if it is done, it is a branch of business which requires careful organisation and watching, and that the development of a system of dealing with consumers is essential and must be adhered to rigidly.

The work divides up into four main classes, consisting of new wiring work, repairs to existing wiring, wiring extensions to old work, and attention to consumers' complaints. Such a business, as will be here described when worked in conjunction with a central station, requires a wiring stores with a small but well-equipped show-room attached. This should be under the charge of a competent stores clerk, whose duties should consist of issuing stores to wiremen, keeping careful costs of the material issued to each job, attending to sales for cash over the counter, invoicing cash sales, taking in all consumers' reports and giving general information regarding wiring work to inquirers. The keeping of all other books, such as purchase ledgers, the invoicing of wiring installations, pricing, checking, stock books, &c., should be in the hands of the chief clerk of the station, in conjunction with the manager.

It is now necessary to discuss under the above-mentioned headings the organisation and running of this type of wiring business.

New Wiring Work.—As soon as a request comes in for an estimate, the leading wireman visits the house, takes particulars, including a rough sketch plan of the house, and makes out a list showing the rooms, the number of points, whether they are for pendants, brackets, or plugs, the number of switches required, &c. This leading wireman, by the bye, is not a walking wiring foreman, as such a man is a useless expense. From the particulars so obtained, a tender is made out in the usual way, and three typewritten copies of the list of fittings are prepared. One of these is sent with the tender, another is kept in the office for reference, and the third is given to the wireman who does the job. When the installation is complete, the wireman returns his copy of the list to the office, and marks on it any extra work or deviation of any kind from his original instructions, so that there can be no mistake when invoicing the job, as the invoice clerk can compare his copy with that of the wireman. This system of lists should be carried out even for adding or altering one single point. It entails very little work, and is an absolute check on the job being correctly invoiced. Moreover, it prevents any dispute arising with the consumer, because he also has his list of the work, the tender for which he has accepted.

Wiring Repairs.—Even in a small electricity supply system with only about 1,000 consumers connected, it is surprising what a quantity of detail is entailed by the branch of wiring business coming under the repairs heading. Where, however, free wiring work is done, an additional complication is the allocation of charges. The most simple system for this branch of the work is to have a counterfoil book with the counterfoil in exact duplicate. The storekeeper writes down the name and number of the job and the work to be done, then tears this out with the remaining two-thirds of the sheet left blank for particulars, which the wireman will fill in. The duplicated slip is, of course, retained in his book. The wireman, on completion of the job, fills in fully what he has done, and exactly what was the nature of the job. These sheets are then sent to the manager every day and he marks upon them an indication as to whether the job is a contract one or free wiring, and whether it is to be charged to the consumer or not. The slips are then handed into the office, and from them the invoices are made up, and the proper allocation of the job in the books is ensured. The chief use of these books is that an exact and correct report of the job is kept, so that the invoice clerk can make up the invoices, giving a correct and full detail of the job. He has not to refer to the storekeeper or any wireman to find out what has been done, and every job is properly allocated by the manager.

Extensions to Existing Installations.—The routine for this section is exactly the same as for new work, with the exception that, in the case of an extension to a free wiring job, the manager should inspect the premises himself, and decide whether it is advisable to go to any further capital expenditure in that particular case.

Consumers' Reports.—It will, perhaps, be astonishing to those central station men who have never had to run a wiring business in conjunction with their legitimate central station work to find how serious a matter these consumers' reports are, and how much attention they require. Out of 900 odd consumers, the average daily number that call with trivial complaints, or else in order to buy a few lamps, or otherwise to ask why the lighting in the cellar jumped at two minutes past eleven last Sunday, or for other equally foolish remarks, is, in the experience of the writer, 14. Taking 310 days in the year, this totals up to 3,400 petty matters occurring in one year, which require some small attention. The writer has found that the simplest way of dealing with the matter, and one that works admirably, is to keep a book, on the left-hand page of which is entered the consumers' name and address, to which is added his wish, or report, or grievance, or whatever it may be. As soon as this has been attended to, the storekeeper, who keeps this book, enters on the opposite page exactly what has been done. If a fuse has been blown, he enters it as having been repaired by so-and-so. If a meter is wrong, he enters it as reported to the meter department. If there is a bad light, he enters it as reported to the manager, and so on. It is found that this book entirely obviates any chance of small orders being overlooked, or of small repairs which cannot be effected at once being left undone or forgotten. In order to make this book completely effective, it must be left with the engineer-in-charge on the evening watch after the stores are closed for the night, and he should enter all reports or telephone messages relating to wiring that he receives during the evening, so that they are sure of proper attention next day by the wiring department.

A wiring business, although perhaps one of the most complicated and troublesome departments of electricity supply work, can, if run on something like the system outlined above, be worked quite easily and efficiently, and—most important point of all—satisfaction to the consumer with regard to his electricity supply can, to a large extent, be obtained by this means.

Overhead Telegraph Wires in London.—On Wednesday, the 12th inst., in the King's Bench Division of the High Court, Mr. Justice A. T. Lawrence, the Hon. A. C. Gathorne-Hardy, and Sir James Woodhouse, sitting as the Railway and Canal Commission, delivered judgment in the case of the Postmaster-General *v.* The Metropolitan Borough of Woolwich. (See ELECTRICAL ENGINEERING, February 6th, 1908, page 187.) The Commission unanimously decided both points raised in favour of the Postmaster-General, namely, that the wires should be attached to wooden poles and overhead in such parts of the borough as he desired.

COMBINED ELECTRICITY WORKS AND DESTRUCTOR STATION AT GREENOCK

THE new combined electricity works and dust destructor at Greenock, the formal opening of which was notified in our last issue, shows a marked improvement over previous works of this class. A new method of charging the furnaces, introduced by the

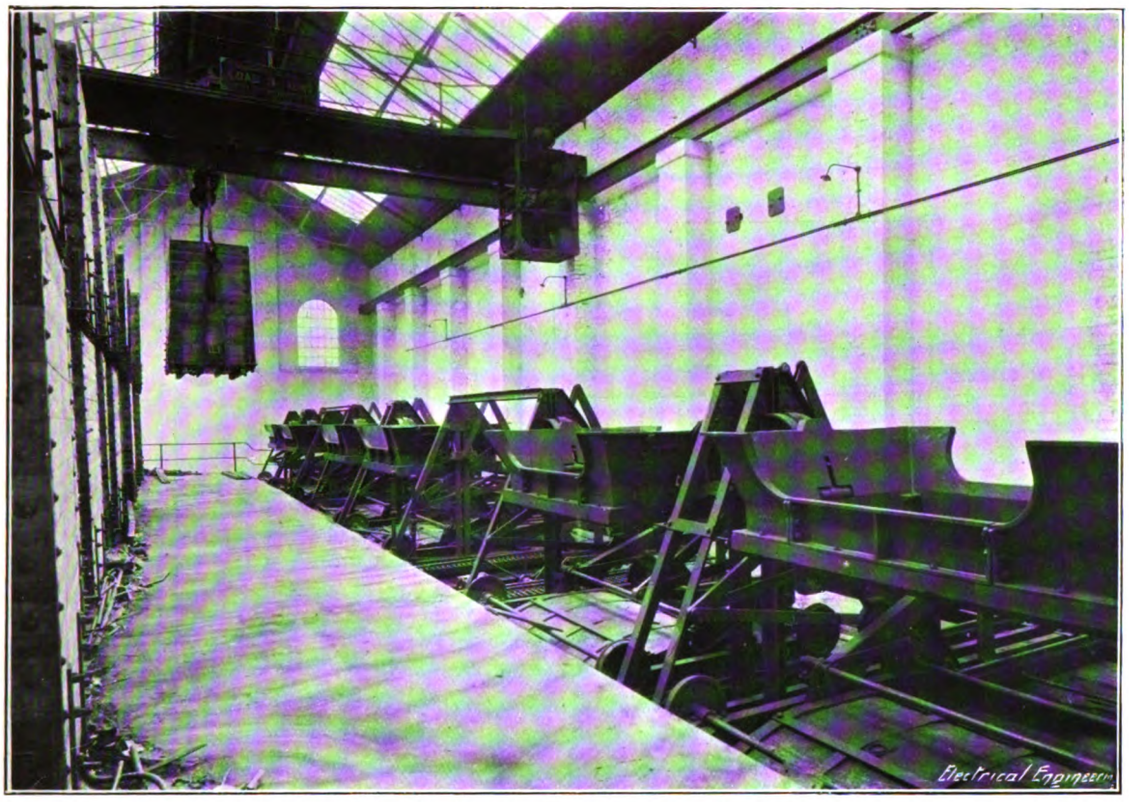

Fig. 1.—Top of the Destructor Furnaces.

Horsfall Destructor Co., Ltd., of Leeds, is made use of, by which all handling of the refuse at the works is rendered unnecessary, and the only extra manual work above that which is required in an ordinary electric power station is the "clinkering"—that is to say, the raking out from the furnaces of the solid products of combustion. An automatic method of performing this latter process has still to be devised.

On arrival at the works, the cart conveying the refuse passes on to a weighbridge, and thence is taken a few yards further to the tipping pit, which is at the same level as the boiler-house floor, and not above the furnaces, so that there is no long incline for the carts to be drawn up, as in some other destructor stations. At the tipping pit, the cart is emptied through a hopper, specially designed to prevent spilling, into a wooden tub, which is just sufficiently large to contain a cartful of refuse. One of these tubs is seen suspended from the travelling crane in Fig. 1, which is a view of the top of the destructor furnaces. A stock of these tubs is provided, and although in ordinary working it is probable that each will be emptied into the destructor furnace as soon as it is filled, they can be used to store the refuse so that their contents can be charged into the furnace as fuel is required. For storage purposes, the platform along the top of the furnaces, seen in Fig. 1, affords sufficient space for storing eighty tubs of refuse. The tub is a strongly-built square wooden box, open at the top, and with hinged lids at the bottom. Normally, these lids are held closed by the rods and hooks, from which the tub is suspended.

The tipping pit has accommodation for four tubs, and there are two filling hoppers arranged to move on rails across the pit, so that the hopper is slid away from the tub as soon as the latter has been filled. The tub is then lifted by the crane to the platform above the furnaces. The top of each furnace is normally closed by a charging door with a water-sealed

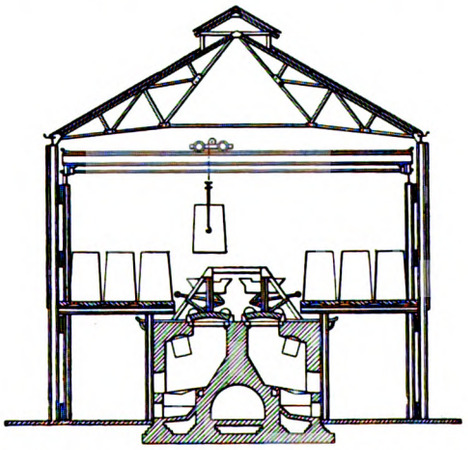

Fig. 2.—Sketch showing Destructor in Cross-section.

seat. As soon as the crane deposits the tub on the movable cradle-hopper above this, the weight of the tub causes this hopper to descend, and, in doing so, it actuates a system of levers and balance-weights, which cause the charging door to be lifted from its water-

Digitized by Google

sealed seat, and pushed to one side, allowing the lower edge of the hopper to descend a very short distance through the charging hole of the furnace. As soon as this has taken place, the hinged lids at the bottom of the tub are automatically opened, and the refuse falls into the furnace. We were able to inspect a charge when we visited Greenock last week to see the new works, and were astonished at the ease, rapidity, and, above all, the cleanliness of the operation. The charging door of the furnace is only open for a few seconds, and the haze of dust usually associated with the conveyance of refuse into a destructor furnace was absent. The speed of charging has also a decided advantage from an economic point of view, as the inrush of cold air and consequent reduction of furnace temperature is reduced to a minimum. Fig. 2 is a sketch showing the destructor furnace in cross section, an idea of the shape of the charging hopper or cradle, and the small dimensions of the actual hole through which the refuse is charged into the furnace is given in Fig. 1, and these two illustrations will help to make the above description clear. The crane used for charging was supplied by Messrs. Broadbent & Sons, of Huddersfield.

Figs. 3 and 4 show the general arrangement of the works in plan and section. It is seen that the building is constructed in four bays. The first of these contains the destructor furnaces and clinkering floor, the second and third the destructor boilers and coal-fired boilers respectively, arranged with their fronts facing one another, and the fourth the engine-room. In this way the clinkering floor, where, of necessity, the atmosphere is laden with a certain amount of fine dust when clinkering is in progress, is at some considerable distance from the engine-room, so that no trouble should be experienced from this. There are six destructor cells, and the gases from them escape by the upper portion of the furnace arch into the combustion chamber at the back of the furnace, which communicates with the boilers. On their way to the boilers, the gases pass through a dust-catcher. Three boilers are fired by the destructor gases, one to each pair of destructor cells. In addition to these three boilers, independent coal-fired boilers are provided, for, as the load on the station increases, and the works are extended, the power furnished by the destructor will be only a small proportion of the total output.

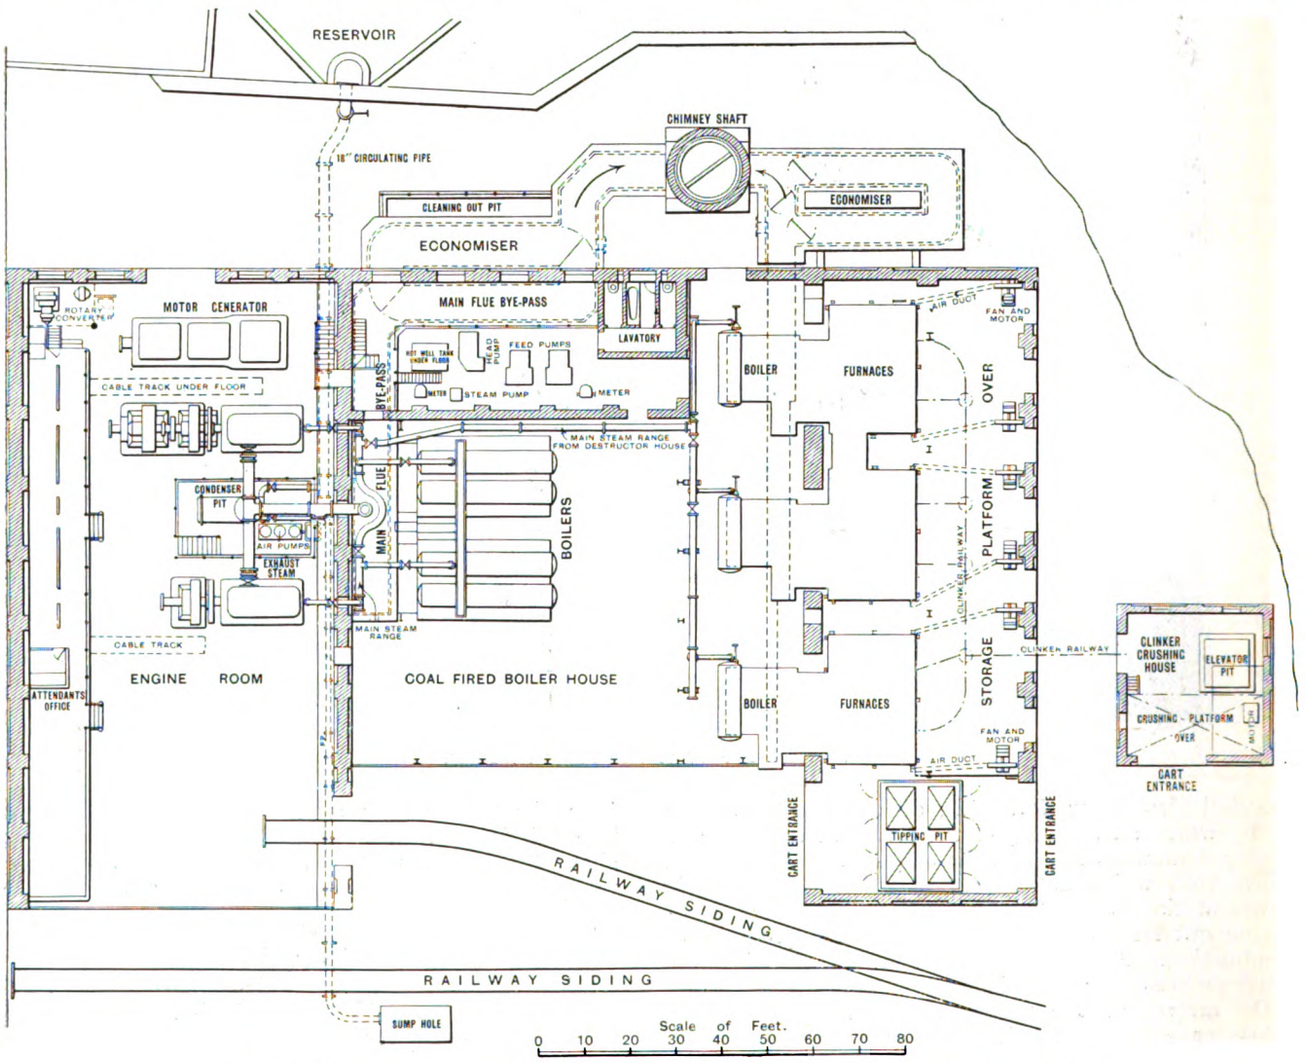

FIG. 3.—PLAN OF THE NEW GREENOCK COMBINED DESTRUCTOR AND ELECTRICITY WORKS.

A good view of the clinkering floor is shown in Fig. 5. As is seen, there is a large door in front of each cell, but two small inspection doors are also provided, through which the firemen can trim the furnace. The furnace grates slope from back to front to facilitate the breaking up and raking out of the clinker, which is often fairly hard. The grate bars are perforated with a number of small holes, and a blast of air at high pressure is forced through them by means of electrically-driven fans. These fans are driven by variable-speed totally-enclosed motors, made by the Phœnix Dynamo Manufacturing Co., Ltd., of Bradford, and the position of the starting and regulating switches, as well as one of the motors and fans, is clearly seen in Fig. 5. The use of a high-pressure

Digitized by Google

blast instead of one at comparatively low pressure is an improvement on some of the older dust-destructors. Steam jets are also fitted to the furnaces, but are only intended as a standby in the event of the fan breaking down. A device is fitted by which the starting switch of the fan is released as soon as the furnace door is

All the flues are lined with firebrick, and in the furnaces specially made fireclay blocks are employed, set in fire-clay cement. The boilers are all of the Babcock & Wilcox marine type, rated at 200 lb. per sq. in. pressure, and they are fitted with superheaters to raise the temperature of the steam to 510° F. In the event

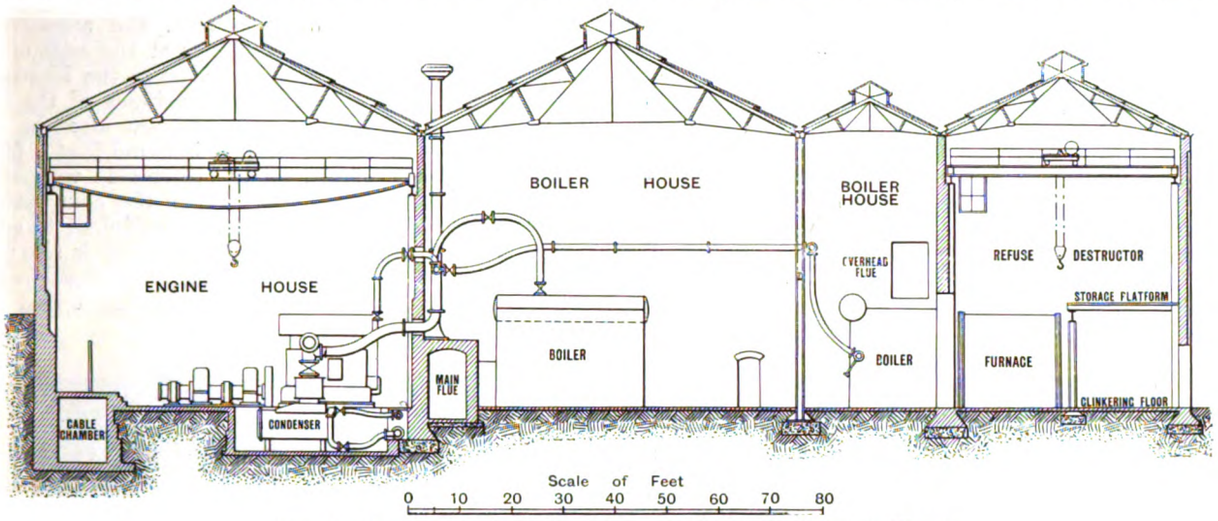

Fig. 4.—Cross Section of the New Greenock Electricity Works.

opened. The fans also serve to ventilate the clinkering floor, and clear the dust and fumes which are emitted when a furnace is being clinkered. This is done by carrying the fan inlets to the under side of the storage platform, and turning them inwards, so that the dust and fumes are drawn in by the fans, and delivered back

of a sudden demand for steam, the destructor boilers can be coal fired on auxiliary grates from the same stoking floor as the regular coal-fired boilers, but this would only be done in emergency, as the coal-fired boilers will be in regular use. The coal-fired boilers (each capable of evaporating 18,000 lb. of water per

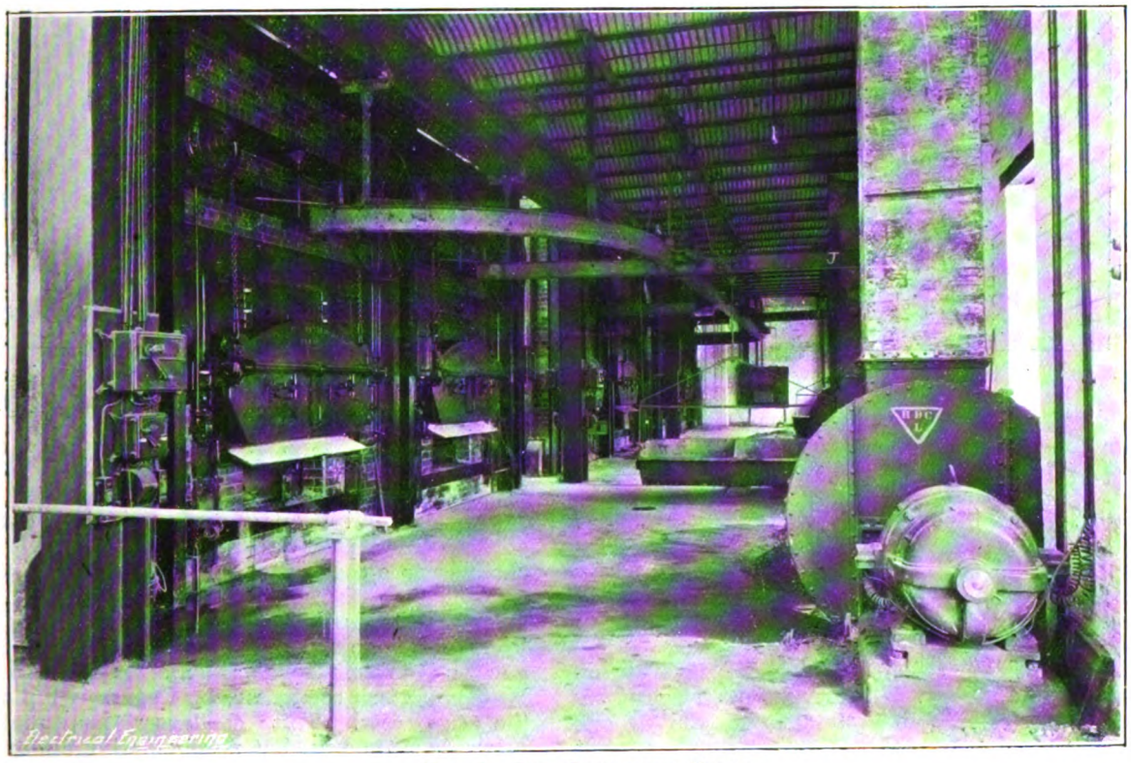

Fig. 5.—The Clinkering Floor.

to the furnaces. It is estimated that the time taken to cremate each cart-load of refuse will vary from one to one and a half hours. When the process is complete, the clinker is raked out into large buckets, suspended from the overhead railway seen in Fig. 5, and is either deposited in heaps, or may be delivered directly to a clinker crushing and screening mill.

hour) are fitted with Messrs. Babcock & Wilcox's most recent pattern of chain grate, which was described in our columns on December 19th last in connection with the new Derby electricity works. A bye-pass is provided from the destructor combustion chamber to the main overhead flue, so that, if a destructor boiler has to be put out of commission, the gases can be led

Digitized by Google

directly to the flue. A Green's economiser with 120 tubes in two sections, and with the usual bye-pass, is also provided. The chimney is 15 ft. in height, and 10 ft. internal diameter.

Messrs. R. Aitkenhead & Sons, of Greenock, were contractors for the buildings and excavator work, Messrs. John M'Ewan & Co., of Greenock, supplied the steel work, and the carpenter work was done by Messrs. J. Miller & Co., also of Greenock.

The general arrangement of the steam pipes is seen in the plan and section (Figs. 3 and 4). Messrs. John Spencer & Co., of Wednesbury, supplied this part of the contract, as well as the feed piping. Each pair of destructor cells can be worked independently, and is connected to one boiler, and the steam from all the destructor boilers is led into a single 10-in. main, which is carried to the main steam range against the engine room, as is clearly seen in the plan, Fig. 3. The feed-piping for the destructor boilers is connected by a branch pipe to the system supplying the coal-fired boilers, in such a way that the former can either be fed through their own economiser or from the hot feed mains of the coal-fired boilers. Two electrically-driven Worthington feed-pumps and one Weir double-acting steam pump have been put in; with the exception of the latter, the auxiliaries in the station are all electrically driven. A storage tank of 12,000 gals. capacity is placed over the pump-room, and a Wright combined water-softening and de-oiling plant is employed to treat the feed water.

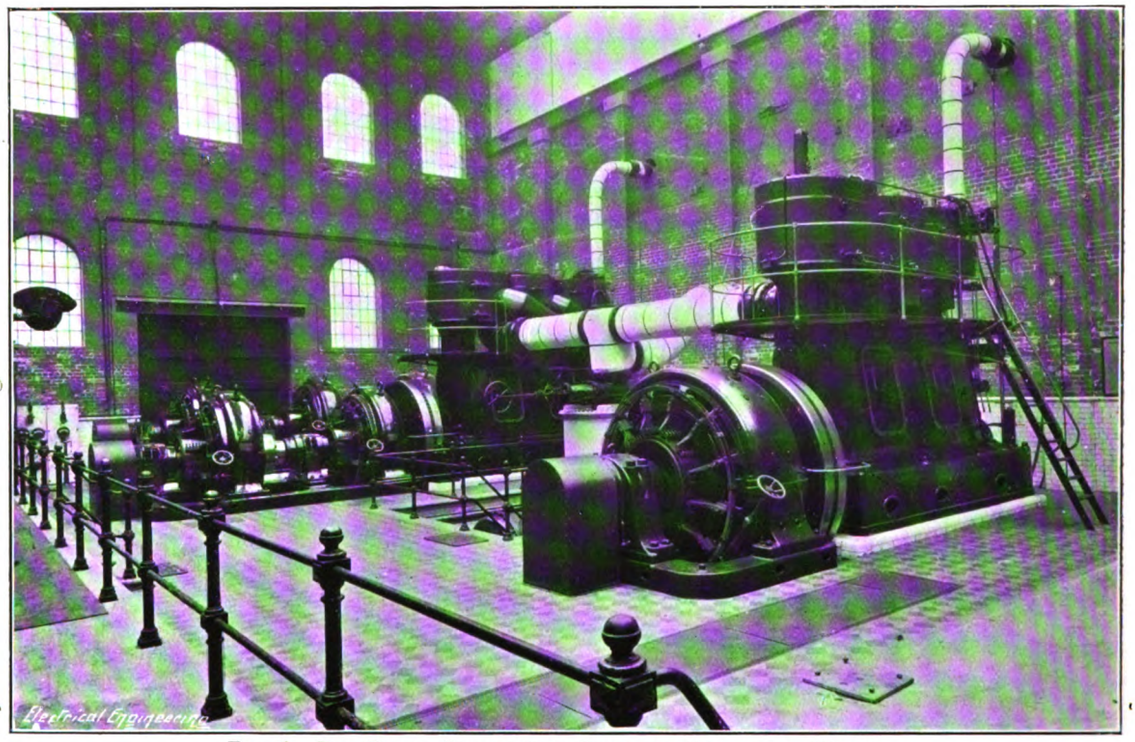

FIG. 6.—THE ENGINE ROOM: NEW GREENOCK ELECTRICITY WORKS.

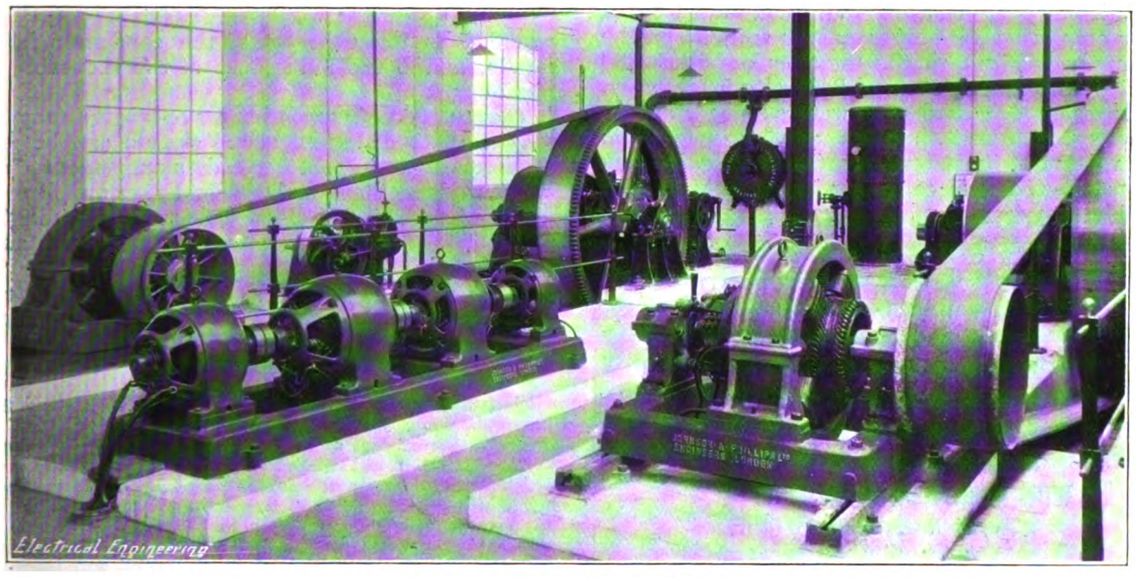
In the engine-room (Fig. 6) are two Belliss-Westinghouse sets, one a 750-kw. machine, the other consisting of two 375-kw. generators in tandem, driven by one engine. The generators of this latter set supply current at 250 volts, while the 750-kw. machine generates at 500 volts. The use of so large a steam balancer is due to the fact that one of the large shipyards which is supplied from the station has 250-volt motors throughout, and when it was changed over to the Burgh mains, it was stipulated that supply should be given at this pressure through an independent feeder, and, if required, from a separate machine. At present, however, the feeder, which is three-wire, is connected to the general bus-bars. For the same reason, the spare plant takes the form of a large motor generator, consisting of a 750-kw., 500-volt, d.c. machine, coupled to two 375-kw., 250-volt, d.c. machines. The armature of the 750-kw. dynamo is interchangeable with that of the 750-kw. steam set, and the 375-kw. armatures of the second steam set and the motor generator are also interchangeable; in fact, the armatures of the steam set have half-couplings at the ends of their shafts, which are boxed in, as seen in the illustration. The fields of the two 375-kw. machines of the motor generator are cross-connected, as are also the fields of the double steam set, and it is found that a 60-h.p. motor can be switched on to either side without any serious variation in voltage. When the next extension is necessary, it will, of course, be sufficient to add an engine to the motor-generator set. There is also plenty of room on the site for several additional machines and boilers, and the building is at present closed by a temporary end.

The generators are 12-pole machines of the usual Westinghouse design. The Belliss engines are triple expansion; they govern on the throttle up to their full loads, and have automatic variable expansion for overloads. A small Worthington pump is fitted on the engine, which pumps oil from the top of the crank chamber to a cooling tank, where it is cooled by pipes connected to the circulating water system, and returned to the crank chamber at a temperature reduced from 130° F. to 95° F. The exhaust steam from both engines is taken through an oil separator to a Mirrlees-Watson surface condenser, in a condenser pit between the two sets. This condenser has motor-driven Edwards air-pumps, but no circulating pump is necessary. Water for condensing is obtained from the town's aqueducts, which bring water down from a lake on a hill above the town for use in several works.

In addition to the sets already mentioned, two small rotary converters with static transformers have been put in to raise the pressure to 3,300 volts three-phase for supply to a hospital about two and a quarter miles distant. These machines take current from the d.c. bus-bars, and, of course, act as "inverted" rotaries.

Digitized by Google

The larger of the two sets is rated at 75 kw., and has a booster on the same shaft for voltage regulation. The smaller set is a 25-kw. machine. At the far end the current is converted to two-phase by transformers with the Scott connection, and the hospital is supplied by the two circuits so far as lighting is concerned, and two-phase for a hoist motor, &c.



The main switchboard is of Westinghouse make. It is on a platform two feet above the engine-room floor. One of the noticeable features is the large number of Aron energy meters on its twelve panels, for metering the current supplied to large power consumers through separate feeders, and another is that the bus-bars (which are in duplicate) are raised on brackets at the back of the board on a level with the top. This makes the back connections easily accessible. The feeders are vulcanised bitumen cables, and come direct to the back of the board, but the machine cables are fireproof.

The conditions at Greenock that rendered necessary the building of a new electricity works were the not unusual ones that the load had increased to such an extent that the capacity of the old works was fully taken up, and there was no space available for the addition of new plant. In addition to a lighting and tramway load, there is a large power load in Greenock; motors aggregating between 4,000 and 5,000 h.p. are connected to the mains. The old station has a plant capacity of about 2,000 kw., divided over eight sets. The new works will eventually be by far the larger of the two. At present it takes a great part of the power load, much of which is supplied to shipyard and other works in close proximity, and assists during the lighting peak. The largest consumer is Caird's shipbuilding yard, in which about 1,300 h.p. is installed, and to which current is supplied at a flat rate of 1d. per unit. The compressers and hydraulic pumps are driven by motors fitted with automatic starters, and lighting also represents a fair proportion of the total consumption in this yard. On a P. & O. liner that is now being built there, about 700 lamps are being used.

The total energy output of the Greenock electricity works has risen from 158,000 units in 1899-1900 to just under 3,000,000 in 1907, about one-third of which is for traction. Treasurer N. M. Brown is Convener of the Electricity Committee, and Councillor J. W. Bennett, Convener of the Destructor Committee. Mr. J. G. Hare, of the Electricity Department, was Architect for the new buildings, and Messrs. Woodrow & Thomson, of Greenock, Measurers and Surveyors. The whole of the work in connection with the combined scheme was carried out to the specification of Mr. J. A. Robertson, Consulting and Resident Engineer to the Greenock Corporation, and we owe him our thanks for showing us the plant and providing us with drawings and other data. To Mr. Parker, his chief assistant, we are indebted for some excellent photographs, a selection of which have been used to illustrate this article.

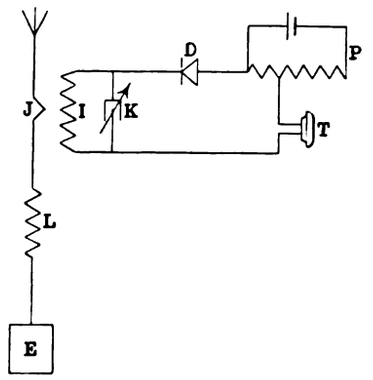
ELECTRIC POWER AT THE FIRST GARDEN CITY

DESPITE the fact that the First Garden City Company had a gas supply in existence at Letchworth, it was decided some eighteen months ago, in consequence of the demand for electric power, to build an electric generating station and lay distributing cables. The plant consists of two gas-driven dynamos, balancers, boosters, battery, &c., and has recently been completed. The dynamos at the generating station are belt driven by two horizontal gas engines, each rated at 100 b.h.p., and are supplied with gas from two suction-gas plants, designed for working with anthracite fuel. There is also an arrangement of town gas connections, so that the engines may be worked either with town or producer gas, and the pipework has been arranged so that the engines can be supplied with producer gas from either of the two suction plants. A view of the engine-room is given below. One of the leading features in the design of the engines is the construction of the bedplate, which is extended underneath the cylinder to the extreme end of the working stroke of the piston, which is claimed to give more perfect support to the piston than is possible when the cylinder overhangs. The engines are provided with balanced cranks, and an automatic lubricating arrangement is fitted to the crank pin so that the engine may be able to run continuously. The engines, which are each provided with a geared barring arrangement so that one man is easily capable of turning the engine into a starting position, are started by means of compressed air contained in a mild steel receiver. A small town gas engine and single-acting compressor are provided to obtain the necessary store of

Interior of the Power Station.

Digitized by Google

air under a pressure of about 150 to 180 lbs. per square inch. The air receiver is of large capacity, and has a sufficient store of air to start the engine several times in succession. The gas plants are of special design, so as to enable continuous runs to be made. They are provided with a water-motor fan for assistance in starting up, thus doing away with the necessity for having one attendant to operate the fan while the plant is being set to work. Each gas plant is provided with two coke scrubbers of large capacity. The dynamos, of Messrs. Johnson & Phillips's standard design, are each of 65 kw. capacity at 500-550 volts, 60 r.p.m. The booster balancer set consists of four machines coupled together on one bedplate. The two balancers mounted in the middle are capable—when not driving the boosters—of dealing with an out-of-balance load of 80 amps. The machines are cross compound wound, so that the E.M.F. on the overloaded side is automatically increased by one volt for every 10 amps. out-of-balance. The battery charging boosters give 50 amps. at any voltage from 2–90. The three-wire switchboard consists of panels to control the two dynamos, balancers, boosters, battery, two feeders, with the usual B.O.T. earth panel. The battery is of the D.P. type, and consists of 260 cells of the L type capable of giving a discharge of 30 amperes for 10 hours, with a final voltage of 1·85 per cell. The cells are in glass boxes mounted on insulators and trays in the ordinary way. The plates are of the D.P. standard pattern, the positives being the heavy cast plant type with D.P. special formation, and are separated by three rows of glass tubes held in position both at the top and bottom of the cells. The battery is erected on strong double-tier wood stands, coated with anti-sulphuric enamel, the stands being fitted together without any metal fastenings. The cables used in the generating station are V.I.R. insulated, the battery regulating cells cable connections having an additional lead covering to protect them. One feeder has up to the present been installed with distributors to the various factories. The cables are triple concentric paper-insulated and lead-covered, laid in wooden troughing on earthenware bridge pieces and covered by tiles. Supply is given to the factories at either 480 volts or 240 volts for power, and 240 volts for lighting. Service boxes of the usual type were supplied, and in each factory a cut-out, switch, supply meter and maximum demand indicator were fixed. The tenders for this installation were called for in December, 1906, to a specification drawn up by the consulting engineers, Messrs. O'Gorman and Cozens-Hardy, and, with the exception of the buildings, the whole contract was placed with Messrs. Johnson & Phillips (Limited), Charlton, Kent, who sublet the gas engines and suction plants to the Campbell Gas Engine Company, and the battery of accumulators to the D.P. Battery Company (Limited).



THE MEASUREMENT OF WAVE-LENGTHS IN WIRELESS TELEGRAPHY

By C. C. Monckton

WITH the near approach of the international control of radio-telegraphy, the standardisation of wave-meters has become a matter of considerable importance. Standard international inductances and capacities are required, for, with these fixed, the true principal wave-length of a station can easily be ascertained.

That considerable accuracy is necessary may be judged from the fact that, with a fleet of ships, it may be found convenient to employ different sending-waves from each ship, and receive diplex from any two with waves differing only two per cent. in frequency. It would appear probable that the existing standards are not widely different, as the writer recently measured the wave-lengths of several ships about 50 miles distant, and he was afterwards informed that his measurements were within half per cent. of those taken on the ships with standard inductances and capacities of another nation.

The writer used an arrangement for measuring the wave-lengths of the receiving circuits, which he does not think has previously been published. In the diagram, J is a single turn of inductance in the aerial circuit, and I is a coil of standard inductance, its distance from J being capable of variation. K is a standard variable air condenser, D a detector, P a potentiometer arrangement, and T a telephone receiver. The two re-

ceiving circuits are brought into tune by varying the inductance L and the capacity K. The coil I is then moved away from J till the sound in the telephone receiver is just audible; it will then be found that, when the circuits are in good tune with the sending station, if the capacity is altered in the slightest degree either way, the sound in the telephone receiver is lost.

The wave-length λ can then be calculated from the formula:

$$\lambda = 60{,}000\sqrt{CL},$$

where C is the capacity of the condenser in microfarads, and L the inductance of the moveable coil in millihenrys.

This method of measuring wave-lengths may be employed up to distances where signals can be received satisfactorily. In the actual arrangement used, a standard inductance and air condenser supplied by the Lodge-Muirhead Wireless Telegraph Syndicate was used. Two forms of detector were employed, and both were found equally satisfactory, the lead peroxide detector of Brown made by the Cambridge Scientific Instrument Co., and a microphonic carbon-steel detector made by Mr. H. W. Sullivan.

Electrification of Suburban Lines in Paris.—In alluding to the proposals made by the Western Railway of France for the electrification of part of its suburban lines, the *Railway Gazette* states that the object chiefly aimed at is to relieve the six tracks, which form the approach to the Saint Lazare terminus, of the heavy suburban traffic they now have to carry. It is proposed to have a new station under the existing terminus, with a separate approach from the Cour du Rome. The electric lines will start on the left of the existing tracks, will burrow under the Versailles lines and cross them again on viaduct, so as to allow them free communication with the Batignolles goods yard. At Asnières the electric lines will divide into two independent branches, one for Saint Germain and the other for Argenteuil. The Saint Germain and Argenteuil lines together carry about 12,000 passengers per hour during the rush hours under existing conditions, and the company hopes to double this carrying capacity with electric traction, by running 20 to 24 trains an hour during those periods. It is expected that the journey-time Paris-Saint Germain will be reduced from 44 to 23 minutes, and Paris-Argenteuil from 25 to 11 minutes, and there is some idea of refusing to carry luggage and parcels during the morning and evening rush hours. The total cost of the improvements contemplated by the company is estimated at £2,480,000, including £320,000 for a generating station.

STEEL-TOWER TRANSMISSION LINE CONSTRUCTION IN SWEDEN

A POWER transmission installation having some features of especial interest is described in *Elektrische Kraftbetriebe u Bahnen*. The installation supplies power to the town of Westervik, in the south-east of Sweden. Power is generated three-phase, at a pressure of 10,000 volts, and is transmitted at that pressure by an overhead line to the transformer and converter stations at Westervik. The power station is situated

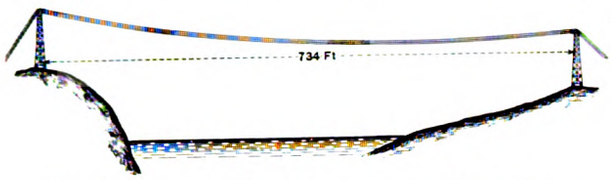

Fig. 1.—General Proportions of the Long Span.

at Tofvehult, some 14·5 km. (nine miles) distant from Westervik. The plant is to consist of three units, two of 325 h.p. each, and one of 650 h.p. The first two only are at present installed. On account of the natural canal formation at the falls where the power station is situated, the total cost of the constructional work and buildings (exclusive of machinery) works out at only £5·6 per kw. installed.

The two water-turbines, which run at 250 revolutions per minute, showed on full load test an efficiency of 81 per cent., and, on suddenly taking off the load, the observed change in speed was only 6 per cent. The direct-coupled generators are rated at 285 K.V.A. each, and generate direct at 10,000 volts. The former-wound coils of the stators are insulated with oiled linen and painted with black insulating varnish. In order to conduct away any static charge on the high-pressure line, each phase is connected to earth, at the power station, through a column of running water; on account of the high specific resistance of water, the current leaking to earth through this column is only 0·036 amps. per phase.

Half-way between Tofvehult and Westervik there is a deep inlet of the sea. To carry the transmission line round this would have increased the length from 14·5 to 20·5 km., and consequently it was decided to carry the line straight across the inlet.

Steel towers of special construction have been erected on either side of the inlet, the span between them being 735 ft. The towers are 70 ft. high, and the minimum height of the cable over the water is 130 ft. These proportions are shown in Fig. 1. The conductors for this portion of the line are of stranded steel wire of 60 sq. mm. (0·093 sq. in.) in section, corresponding to copper wires of 7 sq. mm. section. There are four conductors, three in use, and one as reserve. The mechanical construction of the towers is shown in Fig. 2. Each tower has four brackets, two on either side, which carry the insulating supports for the cables. One of these supports is shown in detail in Fig. 3. It consists of an oak block resting on six high-tension porcelain insulators. The insulators, the iron pins of which are fixed to the bracket, are cemented into the oak block. The upper surface of the block is protected from the rain by a thin zinc covering. In order that any mechanical tension in the cables shall not be transferred to the tower structure, the former are not rigidly fixed to the structure, but are supported on rollers, as is seen in Fig. 3. The flanged rollers rest on a cast-iron plate fixed to the oak block, and on these rollers rests the saddle to which the cable is fixed by means of five clamps. The cable is anchored beyond the points of support, at both ends of the span, and consequently the supporting saddle cannot roll off the bracket. Any movement sideways is prevented by the flanges on the rollers.

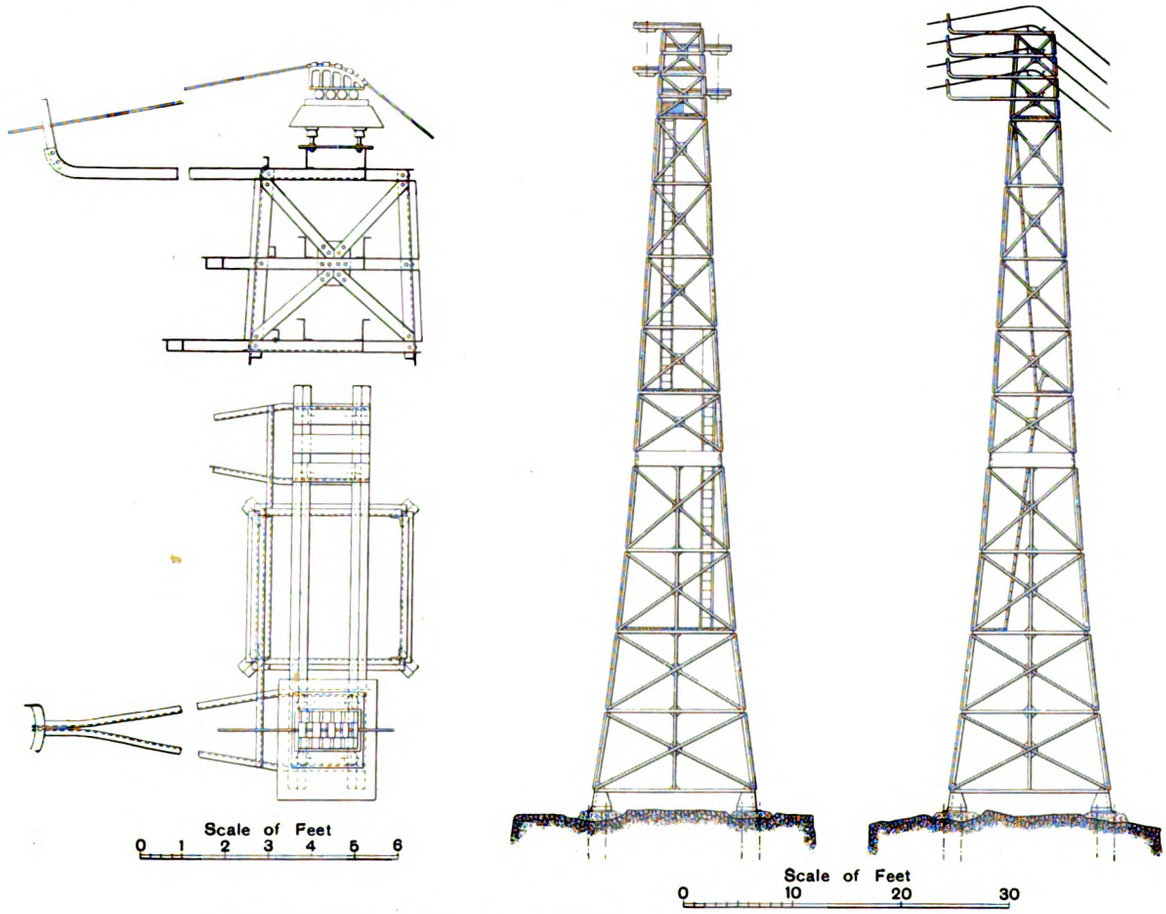

Fig. 2.—Details of Construction of Special Towers for the Long Span.

The tension in the cable at a temperature of −30° C., amounts to 600 kg. (1,320 lb.) between the towers, and 750 kg. (1,650 lb.) between towers and anchors. The maximum tensile stress in the cable is thus 12·5 kg. per sq. mm. (17,800 lb. per sq. in.), which provides a safety factor of 5. At +30° C., the maximum sag is about 30 ft. There is, however, no danger of the cables touching one another, as they are supported at different heights, and 6·5 ft. apart.

It has been noticed that the cables do not swing in the wind,

Digitized by Google

but take up a constant position out of the vertical, remaining relatively at the same distance apart.

A difficult part of the construction was the anchoring of the cables on either side of the span. The cables had not only to be mechanically anchored, but also electrically insulated from earth. The insulators must therefore be able to withstand the mechanical tension of 750 kg., and the electrical pressure of 6,000 volts to earth. Two insulators, each consisting of a porcelain core under compression between iron straps, are connected in series. A thin layer of lead is placed between the iron and porcelain surfaces. The whole is surrounded with a zinc mantle to protect from the rain and mist. The remaining portion of the overhead line on either side of the long span is of the usual construction. The high-tension cables are strung spirally, making a complete revolution every 1·8 miles. A telephone line, also strung spirally, is supported on ordinary insulators below the high-tension line; across the inlet, however, an insulated cable is used.

In the transformer house at Westervik, the three-phase current is transformed from 10,000 volts to 500 volts, for the use of the factories, and some of the power is transmitted by underground cable at 3,000 volts to the converter house, where it is trans-

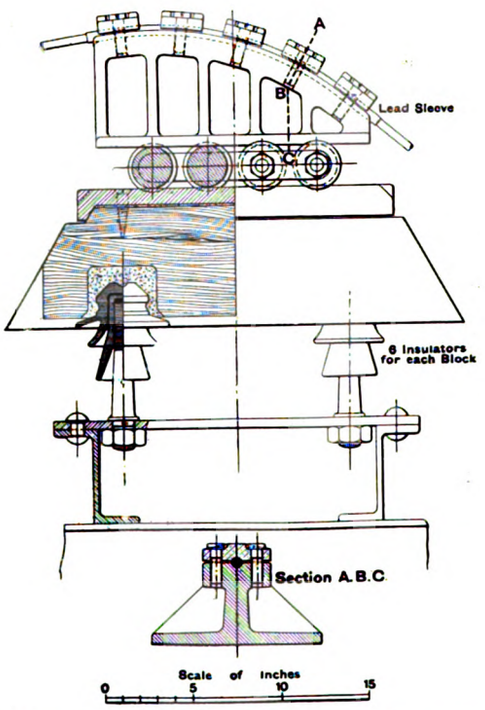

FIG. 3.—SADDLE AND INSULATED SUPPORTING BLOCK FOR STEEL CABLE.

formed to continuous-current at 2×110 volts, by means of motor generators. This station contains at present two motor-generator sets, an accumulator battery, and, as a reserve, the steam-driven generating sets, which were formerly used to supply the town. The following figures for the capital cost of the power station and high-tension line are of interest:—

Hydraulic works and buildings (for maximum 1,300 h.p.)	£5,450
Two water turbines for 325 h.p., 250 r.p.m. each, and two for 45 h.p., 600 r.p.m. each	1,000
Two generators for 285 K.V.A., 250 r.p.m. each, and two 30 kw., 600 r.p.m. each	1,075
Apparatus and Instruments	400
Total	£7,925
Total cost of the high-tension line, including cables, towers, and foundations	£2,300
Total cost	£10,225

The above costs include only the machines at present installed, viz., two for 325 h.p. each. The total cost of the complete power station would be about £9,600, or, taking the value of the maximum output at 880 kw., some £11 per kw. installed. The plans of the installation were prepared by the firm of David Bergman, Stockholm, and the electrical constructional work was carried out by the "Elektriska Aktiebolaget Holmia," Stockholm.

APPLICATIONS OF ELECTRICITY IN SPAIN

THE Commercial Attaché to H.M. Embassy at Madrid, Mr. S. P. Cockerell, in a long report upon the trade and commerce of Spain for the year 1906, has a good deal to say upon electrical and allied matters. The report also contains an appendix, which has been prepared by Mr. Vice-Consul Jackson, who has had a long experience of electrical engineering work in Spain. Mr. Jackson states that the development of the electrical industry is a striking feature of Spanish industrial history in the last decade, but it is regrettable to find that German, Swiss, French, American, and Belgian firms have been almost entirely responsible for this advance; indeed, it may be said that British electrical machinery is almost unknown there. The suggestion is made that it would be advantageous for the British electrical trade if the Institution of Electrical Engineers, or some representative combination of British manufacturers, took steps to have an investigation made into the openings which this country affords.

The number of power stations at the present time is put at 1,165, of which 692 are continuous current, and have an output of 47,533 kw.; 232 are single-phase, and have an output of 15,673 kw.; 70 work upon the two-phase system, and have an output of 7,213 kw.; 137 are three-phase stations with an output of 25,089 kw.; and the remaining 21 are classed as "mixed" stations, and have an output of 6,440 kw. The following list gives the most important towns having electric tramway services, together with the length of line in kilometres: Madrid, 50; Barcelona, 25; Bilbao, 25; Valencia, 20; San Sebastian, 20; Seville, 16; Zaragosa, 11. In the above-mentioned towns there is only one essentially British company, viz., the Seville Tramway Co., Ltd., whose capital, as well as its technical and commercial staffs, are British. In addition to the granting of a large number of tramway concessions during the year, the tram services in the following towns have been changed from animal to electric traction during 1906: Granada, Santander, Zaragosa, Bilbao, and Murcia. The majority of these systems have been constructed by German, Swiss, or United States firms. The report states that most of the tramway undertakings in Spain are worked upon the basis of hydraulic power, generating alternating currents, conversion to continuous current being by means of motor generators. The use of rotary converters is practically unknown in Spain.

With regard to electric lighting, most Spanish towns of any importance have a fair service of public and private electric lighting, but business in this line is not by a long way yet exhausted, as many of the existing installations are deficient, and could easily be reformed, or competition could be effected under favourable conditions. Leaving on one side the question of competition, however, there is still much to be done by way of electric lighting for smaller towns and villages. There are in Spain some 400 towns and villages of over 4,000 inhabitants, where there are no electric power stations.

The electrical material and machinery market is almost exclusively in the hands of Germany, Switzerland, France, the United States, and Belgium. One reason for this is the careful study which these countries have made of the requirements of Spain, and the influx of their capital in the electrical business. Recently there has been an increase in the construction of electrical fittings and machinery in Spain, and, with the protective tariff which came into force in July, 1906, this new industry may yet develop into an important one, though it will always be dependent on the foreign manufacturers, especially German, Belgian, and French firms, as these concerns are principally formed with foreign capital. The United Kingdom, as has already been mentioned, has turned some attention to mining undertakings in Spain. It seems a great mistake, says the report, that British financiers have not taken up Spanish electrical enterprises. There is still a vast field to be exploited, and it should not be allowed to remain in the hands of foreign financiers.

On examining the list of towns and villages which are not yet lit by electricity, it is seen that the north-west region of Spain (Galicia) is almost devoid of electricity. This district is rich in minerals, the country is very fertile, and has the advantage of being near the seaboard, with many good ports.

Street Box Construction.—In July last the County of London Electric Supply Co. was summoned by the Holborn Borough Council for having constructed a street box in Leather Lane, Holborn, without giving notice to the District Surveyor under the London Building Act, 1894. The contention of the company was that the box in question, which was only 32 cubic ft. in dimension, was not a "structure" within the meaning of the Act, and that, therefore, they were not bound to give notice. The stipendary magistrate, however, decided against the company, and fined them forty shillings and ten guineas costs, at the same time expressing his willingness to state a case (ELECTRICAL ENGINEERING, Vol. II., p. 142). The case came before the Lord Chief Justice, Mr. Justice A. T. Lawrence, and Mr. Justice Sutton sitting as a divisional court of the King's bench division on Wednesday last week when the decision of the magistrate was upheld.

PROTECTIVE DEVICES FOR HIGH-TENSION CIRCUITS

DISCUSSION IN DUBLIN.

MR. J. S. PECK'S Paper on protective devices for high-tension circuits, the discussions upon which at Manchester and in London were reported in our last issue, was further discussed last Thursday before the Dublin Local Section of the Institution of Electrical Engineers. In the Paper, which has already been given at some length in ELECTRICAL ENGINEERING (February 6th, page 201), the author considered the nature of the "static" strains produced by lightning, switching, grounding or by any occurrence which causes an abrupt change in static potential, which may appear as high pressure to earth or between wires, or as a concentration of potential upon a portion of the circuit. To relieve the high pressure between line and ground or between wires, lightning arresters are used. To protect apparatus from concentration of potential, choke coils may be placed in series with the apparatus to be protected. Lightning arresters usually consist of an air-gap in series with a current limiting and an arc suppressing device. Four types of lightning arresters are in general use—the horn, the multi-gap, the water-jet, and the electrolytic. The electrolytic is the last type to enter the commercial field, and while the time it has been in active service is short, the author considered that there were indications that it would afford greater protection than any other arrester yet produced.

The Chairman (Mr. T. TOMLINSON), in declaring the Paper open for discussion, mentioned that Mr. Peck had come to Dublin specially to read his Paper. Mr. Tomlinson said that the lightning arresters described in the Paper were really a kind of safety valve, and cited as an analagous case a certain form of mechanical stoker, which had at times been known to jamb, with the result that owing to the large amount of power behind, something had to go, and the makers therefore inserted an intentionally weak pin in one of the pawls, which, whenever the machine jambed, broke, preventing greater damage.

Mr. W. TATLOW mentioned he had received a letter from Prof. Thrift, regretting his inability to be present. Mr. Tatlow thought the author had given an exceedingly lucid explanation regarding the rise of potential between adjacent turns of transformer coils at the instant of switching on. He asked whether the overhead earthed line which was usually erected was being superseded in favour of arresters. He would also be glad to know whether the choke coil inserted between the line and transformer was kept permanently in circuit, or only used for switching operations; if the former, he imagined there would be a good deal of loss entailed. He would further like to know whether the horn type of arrester was not liable to set up oscillations when it operated. It appeared that the Wurts type arrester was only applicable to alternating circuits, therefore, he presumed that it was necessary in the case of direct-current circuits to use either the horn or electrolytic type. He would be glad to know what was the solution used in electrolytic arresters, because he found that with the Nodon valve, in which phosphate of ammonia was used, the aluminium plates were attacked, and he had found that with tungstate of soda the film took a good deal of breaking down.

Mr. A. T. KINSEY thought that telegraph and telephone engineers in adopting the devices described by the author often created the troubles they were trying to avoid. It was now standard practice to earth every pole and arm, so that if a rise of pressure should occur on any section of the line, the current could get to earth immediately, without traversing any length of line, which helped them very considerably, and he had known cases where cattle had been killed at the foot of the poles while the wire remained intact. Mr. Kinsey was rather surprised that the author had not said one word about the fuses used in connection with spark-gap arresters; sometimes these fuses scattered over miles, and miles of line would be blown, causing serious inconvenience: also, he frequently found that in the case of the little spark gaps, consisting of glass tubes with platinum points, that when a spark passed the platinum got deposited the glass, establishing a permanent connection. Regarding transformer breakdowns, they used small transformers in connection with superimposed telephone circuits, and he had had many breakdowns occur between windings. Further, he could fully endorse the author's statement as to the troubles likely to follow the use of circuits, partly overhead, and partly underground, and he had in many cases found the lead covering burned at the points where the underground joined the overhead system.

Mr. G. MARSHALL HARRISS suggested that there was no actual necessity for the use of such devices in this country. He had, however, had some little trouble due to lightning, and was pleased to say how well the Wurts arrester worked; he had stood and watched it act during a thunderstorm, when it responded to almost every flash. He was of opinion that there was no apparatus able to deal with a direct stroke of lightning; if a pole was struck it was immediately splintered into matchwood, and no device could prevent that. Prof. Forbes had once suggested to him that if the line was taken one complete turn round the building, it would probably (owing to the choking effect of even one turn at so high a frequency), prevent the charge entering the buildings and reaching the transformers or machines.

Mr. R. N. TWEEDY mentioned that in tramway work it was generally the custom to insert a choking coil between the busbars and the incoming line, and he considered that the freedom from damage due to lightning was largely due to chokers and the arresters also installed. Mr. Tweedy mentioned that from his experience any arresters having moving parts were entirely useless under severe conditions. He would like the author to inform them as to the steps taken in America to safeguard people who walked under the high-tension transmission lines, as judging from the illustrations shown by the author, there was a distinct element of danger. In England the Board of Trade insist upon elaborate earthed cradles.

Mr. KETTLE (Dublin Corporation Electricity Department), said that many engineers had had painful experience of the destructive effects of pressure surges which occurred on switching in high-tension induction motors and transformers. The resultant breakdowns invariably took place between the individual wires of some of the terminal coils. These individual wires were, of course, only very lightly insulated from each other, although the coils were heavily insulated from the core. With regard to Mr. Tatlow's remarks about the inability of the Wurts multi-gap arrester to deal with direct-current lines, Wurts had also invented a direct-current arrester, consisting of two metal electrodes embedded in a marble slab, the gap between them being bridged by the charred surface of a piece of lignum vitæ, which was in turn covered by another marble slab. The gap between the electrodes held back the line pressure without appreciable leakage, but broke down under pressure surges. He would like to know from Mr. Peck whether the electrolytic arrester was effective for direct current. In his Paper Mr. Peck had dismissed in a few words the water-jet arrester which is used largely on the Continent, in conjunction with a combination of horn arrester and series water resistance. This arrangement had been found very effective, but Mr. Peck condemned it on account of the leakage and the need of water pressure. He had also in his remarks cited the fact that the water-jet arrester always had a horn arrester in parallel with it as evidence that its users had no confidence in it. This was not exactly fair criticism. The electrolytic arrester which Mr. Peck advocated needed, according to him, another arrester in series with it. In fact, it seemed as if the electrolytic arrester performed the functions of a series resistance rather than that of an arrester proper, so that in that respect at any rate, it did not score very much over the water-jet arrester. Besides the water-jet arrester and the combined horn arrester and series resistance performed different functions, the water-jet smoothing down the pressure surges, which might not be of sufficient magnitude to jump the horn gap. The two were thus something like the ordinary and the emergency governors of an engine. The power needed to supply water for the water-jet arrester was a small matter at generating or substations, as where transformers were in use water would probably be used for cooling the transformers. Whilst on the subject of leakage he would like to know whether Mr. Peck had any figures showing the value of the leakage on the water-jet, and also the comparative leakage on the electrolytic arrester, if it were at all practicable to use it alone. Mr. Peck had mentioned as the special feature of the electrolytic arrester that when it came into action it lost nearly all its resistance, and became practically a short circuit, thus affording a free passage for the discharge. This certainly made it a very efficient substitute for the ordinary series resistance, but what would be the effect of two of these arresters discharging simultaneously? Would it not constitute a short circuit on the line, and produce similar effects to two horn arresters without series resistances?

Mr. J. S. PECK (in reply), agreed with Mr. Tomlinson's simile regarding the function of the lightning arrester, which was, as Mr. Tomlinson had said, really a safety-valve to the system to which it was connected. Replying to Mr. Tatlow, he said that the ground wires alluded to gave trouble owing to rusting at the joints, but now much greater care was taken in their erection than formerly. The choke coil was always in circuit with the transformer or other apparatus which it was designed to protect, because disturbances often occur on a line unintentionally, such as earths, short circuits, &c., when an abrupt change may occur; therefore, by constantly keeping the choker in circuit, the apparatus is always protected. He agreed

Digitized by Google

that the horn type arrester might in some cases cause oscillations in the circuit. The Wurts' arrester was only suitable for alternating circuits, but he understood that one was being developed for direct-current circuits, and which was likely to give excellent results. Regarding the permanency of the electrolytic arrester, he knew cases where they had been in service over one year, and no change whatever in the film was found. The horn type of arrester was not, in his opinion, very satisfactory on circuits of 15,000 volts, or less, as the arc does not rise quickly enough. Many engineers had expressed an opinion similar to that of Mr. Kinsey but at the same time trouble due to lightning, &c., were so serious, and the cost of the apparatus so small, that they had tried them; a great number of sceptical users had tested the efficacy of the instruments by inserting a piece of paper between the spark gaps, and found it punctured after a storm, which proved their efficacy. Regarding the transformer breakdowns mentioned by Mr. Kinsey, he rather thought that many telegraph engineers did not appreciate the necessity of thorough insulation for high voltages. He remembered one case in particular, in which transformers and other apparatus were repeatedly being damaged. The complaint was that the arresters were useless for their purpose. Subsequent investigation showed that the insulation of the apparatus was at fault, and on its being increased the arresters acted perfectly, it being, of course, essential that arresters should be set to act at a considerable pressure above that of the line. Regarding overhead transmission lines in America, these are always run through the supply undertakers' own property, a sole right of way being acquired, and overhead transmission lines are not carried through city streets: no precautions are taken on the undertakers' own right of way, as only employés should be there, and they are aware of the existing danger. Mr. Peck explained that water arresters were usually turned off, the water supply only being turned on when storms were anticipated.

COST OF ELECTRICAL POWER FOR INDUSTRIAL PURPOSES

THE discussion on Mr. J. F. C. Snell's Paper on this subject was continued at the Glasgow Local Section of the Institution of Electrical Engineers on Tuesday last week. Previous reports of the Paper itself and the discussions in London, Dublin, and Glasgow, appeared in our issues of January 16th, 23rd, and 30th.

Mr. F. A. NEWINGTON (City Electrical Engineer, Edinburgh) said that the existence of a good diversity factor was of great advantage in levelling the peak loads, but unfortunately very few people even knew what was meant by the term. Mr. Snell and those proposing similar schemes, seemed to think that London was suddenly and urgently in need of 400,000 h.p. of electrical energy; was this really the case?

Mr. F. C. RAPHAEL said that the real difficulty with regard to the electric power question in London would arise from the fact that the powers of the existing companies expired in 1931, so that there would be a natural disinclination to scrap old plant and spend money on new plant, and larger units as that time approached, since the ultimate purchase price of the plant by the local authority would be uncertain. On the other hand, he thought that Mr. Snell's criticism of the present price charged for power by electricity undertakings in London overlooked the fact that they might take into account the ultimate increase in load and consequent cheaper cost of generation. As an analogy, Mr. Raphael took the case of a factory set down with special machines to make a particular article in large quantities at a cheaper price than it could be obtained by the ordinary methods. Until they had reached a certain output at that factory, the low costs of production would not be attained, and there would be no advantage by the manufacture in large quantities. But they would be acting on quite sound business lines to charge the low price for their product at first, so as to reach as rapidly as possible the output which would enable them to sell at this price with a profit.

Mr. STOTHERT (Babcock & Wilcox) said that the cost of generation with the private plant at their works at Renfrew came to from 0·25d. to 0·33d. per unit, or, adding an allowance for depreciation, 0·45d. per unit. They had three 400-kw. sets, and one 600-kw. set, and the load factor was 50 per cent. He had been informed that at Messrs. Watson & Co.'s paper mills the costs were only 0·19d. per unit, including 7 per cent. for interest and depreciation.

Mr. NEWINGTON said that two suction gas plants of 90 h.p. each, one working ten hours and the other five hours a day, had been installed at a general engineering works which previously took power from the Corporation mains at 1·2d. per unit for combined light and power. The cost of running for two months was as follows:—Wages, £100; coal, £133; water, £31; oil, £31; repairs, £8; insurance, £24; total running costs, £327. Adding 10 per cent. for depreciation, interest, &c., on a total capital cost of £3,680, the total cost came to £695, or 1·13d. per unit, in which nothing was included for the rent of land.

Mr. T. C. PARSONS (Burgh Electrical Engineer, Govan) said that, in his figures for graving docks, Mr. Snell should not have taken as a basis for comparison the costs per ton of vessel docked, but per ft.-lb. of water pumped. On this basis the gas engine pump came out 33 per cent. better than the electrical one. Mr. Parsons also took exception to Mr. Snell's dictum that the smaller towns should not have been allowed to build their own electricity works, but should have bought their energy in bulk, and he read out a list of stations taking energy in bulk which had either not shown any profit at all or had made but small profits.

Mr. J. A. ROBERTSON (Burgh Electrical Engineer, Greenock) was able to give some figures (obtained since the last meeting) of the cost of running private plants. In a shipyard which consumed 360,000 units last year, as recorded by a watt-hour meter, the costs per unit had been as follows:—Coal, 0·47d.; oil, 0·08d.; wages, 0·22d.; repairs, 0·21d.; total, 0·98d., with no allowance for depreciation. The plant was belt-driven, and its cost had been £4,000. He also pointed out the small proportion of the cost of power to the total expenditure in a shipyard. Taking as an example the engine and boiler works employing 1,020 hands, referred to in Mr. Snell's Table III., and assuming that the cost paid for current was 1d. per unit, and the average wages 30s. per week, the total annual cost of electric power was only between 5 and 6 per cent. of the wages bill for the year. In a certain shipyard at Greenock the ratio was even less: the wages bill was £135,000, and the total cost of power supplied from the Corporation mains £4,000. Taking account of the extra reliability and the saving in capital costs, there could be very little object in being troubled with a private plant.

Prof. F. G. BAILY (Chairman of the Section) said that if a company or the L.C.C. were to buy out the old stations in London at a valuation taking account of future profits, it would increase the total capital expenditure and electrical energy would cost more than at present. On the other hand, if the stations were not bought out and a new works were started to supply at a cheaper price, it would be robbery. He also expressed his surprise that in Mr. Snell's tables oil engines should show lower costs than suction gas plant.

Mr. J. F. C. SNELL, in reply to the whole discussion, said that Tables I. and II. in his Paper did not include supervision, establishment charges, or rating, nor was any capital charge for spare plant taken in. Since he had written his Paper, more than a year ago, oil had risen in price to 82s. 6d., and as his figures were based on a price of 42s. 6d., a considerable correction must be made. Referring to Mr. Robert Robertson's curves, he said that no user would be found with a 50 per cent. load factor to take power at the prices shown by the curve XY. He defended the £12 per kw. station, and gave the one at the Powell Duffryn colliery, cited by Mr. Sparks, as an example. Referring next to gas plants, he said that he had never been able to get any gas engine plant running in actual practice that consumed only 20 cubic ft. per B.H.P. He knew a case in which a plant was looked after admirably, and consumed 30 cubic ft. per kw.-hour. Much lower consumption, down to perhaps 15 to 16 cubic ft. per B.H.P.-hour had been obtained in tests, but the gas consumption went up considerably when the plant was out of the maker's hands. After apologising for not referring to all the points raised in the discussion owing to its great length, Mr. Snell concluded by replying to Prof. Baily's observation about robbing the existing supply undertakers in London. He would not propose to rob them, but, on the contrary, to supply them at such a price that after adding their present capital charges they could still retail to the consumer at a cheaper rate than their present prices.

Permanent Wireless Telegraph Station at the Eiffel Tower.—The *Engineer* states that the French Government has decided to establish a permanent underground wireless telegraph station at the base of the Eiffel Tower (on which is the aërial) with commodious offices, in place of the temporary buildings now in use. Wireless communication is still being kept up daily with the warship *Kleber* at Casa Blanca.

Overhead v. Underground Telephone Wires.—On Wednesday last week judgment was delivered by the Railway and Canal Commission in the appeal of the Postmaster-General v. Watford Urban District Council. The case involved the point as to whether certain telephone lines should be placed overhead or underground, the Watford Council contending that they should be placed underground. Full particulars of the previous hearing were given in ELECTRICAL ENGINEERING, Vol. II., p. 1014. Sir James Woodhouse, in giving judgment, said that although the amount involved was small, the Postmaster-General had brought the matter into court, as he thought the case raised a question of great importance. If the contention of the Council were upheld, it would cause a serious obstacle to the economical carrying on of the telephone service. The only objection raised by the respondents to carrying the wires overhead was that it would cause an obstruction to the traffic. He had visited the locality, and was satisfied that there would be no obstruction to the traffic by the erection of the six or seven poles proposed, and that the objection of the Council to their erection was not well founded. Mr. Justice A. T. Lawrence and the Hon. A. E. Gathorne-Hardy agreed, and the appeal was accordingly allowed.

A NEW PETROL-ELECTRIC RAILWAY CAR

A NEW railway car for independent use on the Delaware and Hudson Railway in America, propelled by a petrol engine, and employing electrical transmission gear, which has made some recent trial runs, is described in the *Street Railway Journal*. The car was built by the General Electric Co., and differs somewhat from the earlier petrol-electric car, supplied to the same railway. The complete car is 50 ft. long overall, and seats 44 passengers. Its total weight is 31 tons.

The engine drives a 90 kw. continuous-current generator, working at a variable voltage, which supplies current through suitable control gear to two 60 h.p. traction motors. The generating set is placed in a compartment at one end of the vehicle. The engine, which has developed as much as 150 h.p., was specially designed for the work by the General Electric Company, and is of the V type, with eight inclined cylinders, each of 8-inch bore, by 7 in. stroke. A four-throw crank shaft is, therefore, possible. The construction is very light and compact, and all the sixteen valves are actuated by a single cam-shaft between the cylinders. Two carburettors are employed, and high-tension ignition is used, with separate coils for each cylinder and accumulator. For starting the engine, the somewhat unusual plan is followed of providing a special breech block mechanism, which fires a charge of black powder in one of the cylinders. Cooling is on the thermo-syphon system, without pumps or fans, and a large radiator is provided on the roof of the car. Petrol is stored in a 90-gallon steel pressure tank, from which it passes to an auxiliary tank, from which a gravity feed is given to the carburettors.

The generator is a 90-kw. 8-pole, separately excited machine, which has been specially designed with a view to procuring the lightest possible machine for the necessary output. It is provided with commutating poles. At starting, the field excitation is weak, so that large currents are required to give the necessary starting torque. The normal pressure when running at 550 r.p.m. is 250 volts, at which time the current will amount to 360 amps., but at starting, a current of 800 amps. can be secured at a corresponding decrease in voltage. It would be impossible to commutate so large a current in a machine with so great a kilowatt capacity per pound without the use of commutating poles.

The total weight of the generator, including exciter, is only 2,740 lb., while a standard machine of this output weighs 8,600 lb. As is only natural in a machine where the weight has been so materially reduced, the temperature rise is higher and the efficiency lower than in standard apparatus of the same output. The higher temperatures are fully provided for by the type of insulation employed; there is no paper or muslin used anywhere in the machine. The armature coils are insulated with mica, the interpole coils with asbestos, and the field coils are wound with enamelled wire. The armature leads to the commutator are riveted as well as soldered, although the precaution has been taken to use pure tin for soldering, which has a melting point of over 200 degs. C. Air ducts of ample dimensions are provided to insure a large volume of air being circulated through the core. The efficiency is 88 per cent., being only about 3 per cent. lower than a standard machine having a temperature rise of 35 degs. C.

The exciter is a 3-kw. 70-volt, shunt-wound machine, with its armature mounted directly on the armature shaft of the main generator and its field yoke supported by the bearing brackets, enabling it to fit under the back ends of the generator armature windings.

The speed of the motors is governed by a potential control, the generator being separately excited and the terminal voltage of the motors being varied by means of a rheostat in series with the exciting circuit. The armature circuit of the main generator comprises the armature—fuse—two contactors in series, reverser, and the two motors. The motors are connected in series or in parallel, according to the position of the controller handle, and they are grounded to the truck framework, while the solenoid coils for operating the contactors are energised by a storage battery floating across the field circuit. The reverser is operated, as usual, by a separate reverser handle on the controller.

The current from the exciter passes around the field of the main generator and through the rheostat; the function of the controller is to cut in and out this rheostat as occasion demands.

A storage battery which floats on the exciter circuit is used for supplying the lighting circuits and its charging and discharging is controlled by means of a reverse current relay which permits the lights being supplied directly from the exciting circuit or from the storage battery according to the voltage of the exciter circuit. A Tirrill regulator is employed for regulating the voltage on the lighting circuit. These arrangements enable the car lights being used when the engine is at rest.

The master controller, which has some unique features, gives seven steps with the two motors connected in series, and eight steps with the two motors connected in parallel. It is provided with four handles, three of which are mounted one above the other on concentric shafts. The function of the top handle is to advance and retard the ignition of the engine, the second controls the throttle of the engine, while the third handle controls the generator field resistances and the contractors, which establish the circuit for the motors, besides transposing the motor connections from series to parallel. The fourth handle operates the reversing switch and controls the direction of rotation of the motors.

The car is heated by passing part of the exhaust gases through pipes suitably located in the car body. The air compressor for the brakes is coupled directly to the engine. The arrangement of the motor on the trucks, one mounted on each, does not call for particular remark.

On a recent trial trip of about 78 miles, including 23 stops and a number of slowdowns due to signals, the speed of the car varied from 23 m.p.h. on a 1·3 per cent. up grade to 56 m.p.h. on a ¼ per cent. down grade, except where traffic conditions and road regulations required lower speeds. Where traffic conditions permitted, a speed of 50 m.p.h. was recorded on level track, and from Albany to Mechanicsville a speed of 47 m.p.h. was sustained on a steadily rising grade.

LONDON ELECTRIC LIGHTING ACCOUNTS

CENTRAL ELECTRIC SUPPLY CO.—The Report for 1907 states that energy has been supplied to the St. James's and Pall Mall Electric Light Company, Ltd., and the Westminster Electric Supply Corporation, Ltd., throughout the year, to an amount of 17,431,370 units. After making a full allowance for sinking fund and depreciation, the net balance for the year 1907 is £5,036, and adding balance brought forward from 1906, the amount now to be dealt with is £5,042. A dividend of 5 per cent. on the ordinary shares for the year is recommended, carrying forward £42 14s. 0d. Reference is made in the report to the Bill to confer further powers upon the company in conjunction with certain other of the West End electric lighting companies.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING CO.—The report for the year ending December 31st, 1907, states that the number of houses and shops connected with the system has increased from 3,977 on December 31st, 1906, to 4,172 on December 31st, 1907, while the number of lamps calculated on the usual basis of 8-candle power has increased from 353,532 (10,600 kw.) to 383,200 (11,500 kw.). The renewal account now stands at £69,602, an increase of £3,223. After providing for the amount placed to renewal account, and after paying the dividends on the 6 per cent. first preference shares to June 30th, 1907, on the 5 per cent. second preference shares to September 30th, 1907, and an interim dividend at the rate of 10 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to the credit of the nett revenue account for the year 1907 is £9,854. The directors draw attention to the fact that the rate of dividend has been maintained, despite the high price of coal and the large amount paid in respect of local taxation, which latter item alone now amounts to a sum equivalent to about 6 per cent. on the ordinary shares. Of the above sum £1,500 has been appropriated to the payment of the first preference dividend to the end of the year, and £625 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date. It is proposed to pay out of the balance of £7,729 a further dividend on the ordinary shares at the rate of 10 per cent. per annum, for the past half-year, making with the interim dividend paid on August 1st, 10 per cent. for the year. This will leave a balance of £2,479 to be carried forward. After the general meeting on the 27th inst., there will be an extraordinary general meeting for the purpose of confirming the resolution passed on the 6th inst., relative to the Bill now being promoted by this company in conjunction with four of the other electric supply companies in London.

LONDON ELECTRIC SUPPLY CORPORATION.—The report for the year ended December 31st, 1907, shows a profit of £46,319, to which has to be added the amount brought

Digitized by Google

forward, £4,170, less interest on temporary loan and expenses incurred in Parliament last Session, viz., £900, making a total of £49,589. Out of this the interest on debenture stock to December 31st, viz., £14,975, has been paid, leaving a balance of £34,613. The Board propose a dividend of 6 per cent. on the preference shares for the year (of which an interim dividend of 3 per cent. was paid on September 1st, 1907), viz., £20,952; a dividend of 2½ per cent. on the ordinary shares for the year, viz., £8,325; to reserve account (making a total of £57,500), £2,500; to carry forward, £2,836. The number of units sold amounted to 10,011,987, as against 10,544,484 last year. The diminution in the revenue account is caused by the large decrease in the receipts from the London County Council for their tramways, as compared with last year, together with a considerable increase in the price of coal. On the other hand, the power supplied for industrial purposes shows an increase from 840,634 units to 2,111,921, and the general business (excluding that of the London County Council) shows an increase of over 30 per cent., viz., from 5,420,258 to 7,118,513 units. It is expected that a commencement will be made in May next to supply power to the London, Brighton and South Coast Railway Company for working the trains on their South London line between Victoria and London Bridge. The directors have joined with other electric supply companies in London in depositing a Bill in the coming Session of Parliament for conferring further powers upon all the companies, in order to obviate the necessity for, and to take the place of, the various Power Bills which have been promoted during the last three Sessions. Such Bill would utilise the existing plant for the best and meet the public demand for cheaper, *i.e.*, for centralised power supply. An extraordinary general meeting will be held at the conclusion of the general meeting on the 27th inst., for the purpose of considering and approving this Bill.

NOTTING HILL ELECTRIC LIGHTING CO.—The report for the year 1907 shows expenditure on capital account of £2,168. The capital account now stands at £233,526. The expenditure on capital account exceeds the receipts by £25,526. The cost of the joint station to date has amounted to £184,049, and joint debenture stock amounting to £180,790 has been issued. This stock is subject to a cumulative sinking fund, which now amounts to £24,390, invested in trustee securities. There are now connected to the mains the equivalent of 160,349 8-c.p. lamps. The number of consumers is now 2,673, and 98 per cent. of these are supplied at 200 volts. The gross revenue for the year was £38,055, showing an increase of £1,131, and the total net profit was £19,007. From this there have to be deducted depreciation, renewal and reserve fund, £2,000; debenture and other interest, £2,586; Kensington and Notting Hill joint debenture stock—interest £2,216, sinking fund, £1,154; reserve for bad or doubtful debts, £50; leaving a balance available for dividend of £11,000. The directors recommend the usual dividend of 6 per cent. (less income-tax) on both the preference and ordinary shares, and that the balance be divided in accordance with the articles of association, one half being credited to the founders' shares, and the other half to the ordinary and preference shares. This will enable a further 1 per cent. to be paid on both ordinary and preference, with a distribution of £2 15s. per share on the founders' shares. An interim dividend of 3 per cent. was paid to the holders of the ordinary shares on July 1st, and the balance of 4 per cent. will be paid forthwith, together with the distribution on the founders' shares. The preference shares having received their full 6 per cent., the 1 per cent. bonus will be added to the interim dividend on these shares, to be paid on July 1st next. The reduction in the net profit is more than accounted for by the increased costs at the Wood Lane works during the latter half of the year. This was occasioned partly by the increased price of coal, but mainly by the cost of exceptionally extensive repairs which had to be carried on under unfavourable conditions, owing to the impossibility under the existing Electric Lighting Acts of obtaining current by joining up with neighbouring companies. The rates paid to the local authorities (including this company's proportion of those charged in the Wood Lane supply) amounted to £3,475, approximately equivalent to a dividend of 2½ per cent. on the share capital. The law and Parliamentary costs for the year amounted to £202 17s. 2d., and were incurred in promoting one Bill and opposing others in conjunction with the other electrical supply companies in London. None of these, however, were passed during the Session. In conjunction with its neighbours (the Kensington and Knightsbridge Electric Lighting Co., Ltd., the Westminster Electric Supply Corporation, Ltd., the St. James's and Pall Mall Electric Light Co., Ltd., and the Central Electric Supply Co., Ltd.), this company is promoting a Bill in the present Parliament for the purpose of enabling a close working arrangement and means for interchange of current to be made between those undertakings, the experience of the past year having shown this to be very necessary. The Bill was fully explained and approved by the shareholders at a Wharncliffe meeting held on the 3rd inst., and a further meeting to confirm this resolution will be held after the ordinary general meeting on February 25th.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO.—The report for 1907 states that the supply has been distributed from the Carnaby Street and Mason's Yard works of the company to the equivalent of 341,428 lamps (10,926 kilowatts), being an increase of 32,444 lamps (1,038 kilowatts). For this purpose 5,429,190 units were generated at the company's works, and 5,286,440 units were purchased from the Central Electric Supply Co., Ltd. The Central Electric Supply Co. has declared a dividend of 5 per cent. on the ordinary shares, in respect of which a sum of £2,500 will be payable to the company. In conjunction with the Westminster Electric Supply Corporation, Ltd., the Central Electric Supply Co., Ltd., the Kensington and Knightsbridge Electric Lighting Co., Ltd., and the Notting Hill Electric Lighting Co., Ltd., a Bill is being promoted in the present Session of Parliament, with the principal objects of securing additional economy of production and regularity of service by linking up their several sources of supply in the West End of London. The net profits for the year 1907 amount to £27,889, to which is added £486 balance from last account, making £28,375. Deducting interim dividend for the June half-year, there is an amount now to be dealt with of £14,875.

WESTMINSTER ELECTRIC SUPPLY CO.—The report for the year 1907 states that the output of electrical energy, which on December 31st, 1906, amounted to the equivalent of 859,004 8 c.p. lamps, had increased by December 31st, 1907, to the equivalent of 929,579 lamps, the largest addition in any one year. A considerable part of this addition is for power and heat, for which there has been an increasing demand during the last few years. The length of roadway in which continuous current mains have been laid now exceeds 84 miles, making about 329 miles of ways, into which upwards of 258 miles of copper (strip and cable) have been drawn. In addition, five miles of trunk mains (24 miles of ways) are laid in the company's area, to connect the stations with the Central Electric Supply Company's station at St. John's Wood. A copy of the accounts of that company is enclosed herewith for the information of shareholders. The London County Council have now handed over to the company the new site for a station in Horseferry Road, in accordance with the provisions of the London County Council (Improvements) Act of 1900, which, as mentioned in last year's report, is to replace the company's present station in Millbank Street. The directors have placed the contract for the new buildings of the station, and the work has commenced. The sum to be paid by the London County Council in connection with the reinstatement is to be settled shortly by arbitration. An interim dividend, at the rate of 10 per cent. per annum on the ordinary shares, and the dividend on the 4½ per cent. preference shares, for the half-year ending June 30th, 1907, has been distributed. After allowing for depreciation, sinking fund, and other charges, the net balance is £36,997, from which must be deducted the second half-year's dividend on the preference shares, which absorbed £8,636, leaving a balance of £28,313. Out of this the Board recommend the payment of a dividend at the rate of 10 per cent. per annum, less income tax, for the past half-year, carrying forward a balance of £2,185. Although the output has increased during the current year, the amount available for net revenue has diminished principally owing to the heavy amount paid in the City of Westminster for rates, which now amounts to £16,000 (equal to nearly 3 per cent. dividend on the ordinary share capital). Other contributory causes are the large increase in the price of coal and the investment of a sum of £245,000 in first-class securities on account of depreciation and reserve. The sum thus invested, though bringing in a smaller rate of interest than if employed in the business, places the company in a very strong financial position, which the directors feel sure the shareholders will appreciate.

Noisy Operation of Dynamos.—An article by N. R. Craighill in the *Electrical World* (New York) discusses the question of the noisy running of electric motors and generators, a matter to which attention has been called several times lately in discussions at the Local Sections of the Institution of Electrical Engineers. The author states that in order to obtain noiseless operation, the pole-face density should be not more than 50,000 lines per square inch for medium and large-sized machines, and for small ones considerably less. When this density is exceeded, it is practically impossible to prevent noise. A large number of slots per pole and large air-gaps are conducive to quiet operation, but both lead to uneconomical designs. The pitch of the note given out by a machine depends, of course, upon the number of teeth in the armature and the speed of the same, but the possibility of having noisy running depends upon certain relations between the slot pitch and the length of the pole arc. As the result of experiments it was found that the noise could generally be eliminated by a slight trimming of the pole tips, but still further trimming resulted in alternate noise and quiet. The more nearly the ratio between pole-arc and slot-pitch lies midway between two whole numbers, the less tendency there will be for a machine to hum. Thus for quiet operation, the ratio pole-arc to slot-pitch should be equal to a whole number, plus one half. When the pole tips are rounded, the effective length of the pole arc must be used to obtain this ratio.

THE PETROL-ELECTRIC SYSTEM FOR OMNIBUSES

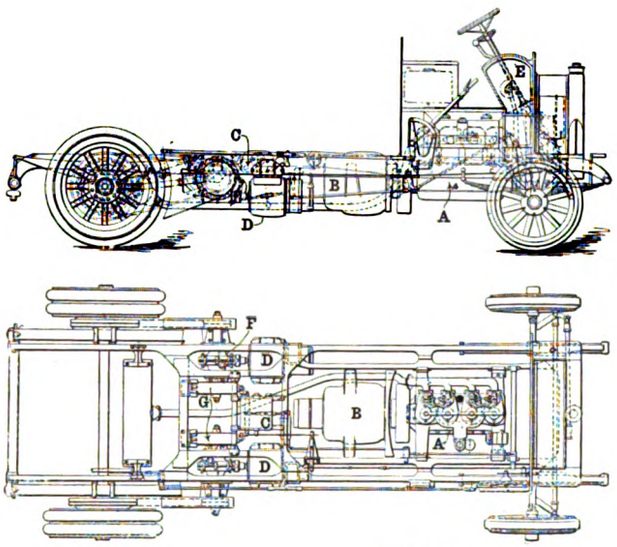
MR. BERNARD HOPPS (of the British Thomson-Houston Co.) read a Paper on Thursday last before the Rugby Engineering Society entitled, "The London Motor Omnibus Problem, with Special Reference to the Petrol-Electric System." The introductory portion of the Paper briefly sketched the course of events which have led up to the present state of affairs as regards motor omnibuses in London, of which there are now over 900 on the streets. The trouble experienced with older types of vehicle and the effect of the Scotland Yard Regulations were mentioned, and a few words were said as to the relative advantages of different forms of motive power.

In turning to petrol-electric systems, the author said that the first aim in designing a 'bus for London service should be to reduce everything to the simplest possible form. The temptation is often great to introduce some device, more or less complicated, which produces a refinement in the control, as, for example, electrically controlled throttles, &c., whose action depends more or less on a fine adjustment, but which, in the hands of the average London 'bus-driver, is very soon rendered inoperative. The electrical equipment must be self-contained, and sturdily-built, and should be so simple that it can be taken to pieces and re-erected satisfactorily by an ordinary fitter.

Petrol-electric systems may be roughly grouped under the following headings :—

(*a*) Those which start and accelerate electrically, after which the electric drive is cut out and is taken up by a clutch driving direct through from the engine. (An example of this class is the Hart-Durtnall system, described in ELECTRICAL ENGINEERING, Vol. I., p. 147.)

(*b*) Those which employ accumulators to assist the engine in climbing grades, &c. (Such as the "Autcmixte" or Pieper system.)



(*c*) Those which drive entirely electrically (including the Stevens, Greenwood & Batley, Kriéger, Mercedes—Mixte, and other systems, as well as that of the author's own firm. See ELECTRICAL ENGINEERING, Vol. I., pp. 461, 690, and January 16th, p. 83.)

It is claimed for the first method (*a*) that since the electrical equipment is only used for starting and accelerating, it can be made comparatively smaller, lighter, and cheaper. This was characterised by the author as an erroneous idea, as it was not practicable to limit the output of the electrical equipment to starting and acceleration duties only, since occasions may arise where hills of considerable length must be negotiated, the gradient of which will be too severe for the direct drive, and which, therefore, must be climbed entirely through the electrical transmission. Since such grades represent the most severe duty for the electrical equipment, it followed that in order to avoid overheating, it must be made almost as large and heavy as would be necessary were it called upon to propel the vehicle during the whole of the working period. It may be said that for service in our large cities, as, for example, London, the grades encountered are insignificant, and can be surmounted with the direct drive; but for this class of service where traffic is always congested, and where constant stops and starts are necessary, he thought there was no real advantage in employing a direct drive to decrease the duty of the electrical equipment, since it cannot be used for sufficient length of time.

It is further claimed for this system, he continued, that the so-called direct drive at full speed is more efficient than a purely electrical transmission. Assuming that this is so, and that a few per cent. saving in efficiency may be obtained owing to the elimination of the electrical losses, which at full speed, however, are at their minimum, this arrangement introduces a clutch, which complicates the control and adds another item to upkeep. It also necessitates the alignment of the motor, generator, and engine. It limits the speed of the motor to that of the engine, whereas with a purely electrical drive the motor can safely be run at double the speed of the engine with a corresponding saving in weight and cost. This system may possibly have advantages for driving light pleasure cars, but in the author's opinion it has none when applied to motor omnibuses for London or similar service. With regard to the second system (*b*) in which accumulators are used to assist the engine, it is somewhat difficult to see what advantage is obtained by their introduction; they add a complication, and require a special organisation to attend to them. The accumulator usually employed is a Plante type, which it is true will withstand a considerable amount of abuse both as regards heavy discharges and vibration, but the battery required is as heavy, and as costly as an electric motor would be, and far more expensive in upkeep. The simplicity of the control is sacrificed, and a skilled driver is essential to operate such a system efficiently. For heavy country service, in which long steep hills have to be negotiated, the discharge rate on the accumulators is high, and there is the possibility that they may become totally discharged before the top of the hill is reached. The only advantage that can be claimed for such a system is that of recuperation during the braking and coasting periods.

There remains the third system (*c*), which was that adopted by his own firm. This consists of a direct-current dynamo driven by a petrol engine, the whole of the engine power being converted by the dynamo into electrical energy, which is transmitted through a controller to the motor, or motors, driving the road wheels. In this system either one or two series-wound motors may be used, depending on the nature of the service. The chief feature of this system is the constant watt output self-regulating dynamo, which reduces the control to its simplest form, and thus renders the employment of skilled drivers unnecessary.

In order to fully appreciate the advantages of this machine, it is necessary to study the characteristic of the petrol engine that drives it. The maximum h.p. that can be developed by a petrol engine is limited to practically its normal working out-

A. Engine.
B. Auto-Regulating Generator.
C. Controller.
D. Series Wound Motors.
E. Operating Box.
F. Worm Reduction.
G. Countershaft Brakes.

ELEVATION AND PLAN OF OMNIBUS CHASSIS, FITTED WITH B.T.-H. PEIROL-ELECTRIC SYSTEM OF TRANSMISSION.

put. The torque developed remains approximately constant; it follows, therefore, that as the speed diminishes, due to overload, the h.p. developed diminishes, and this at the time when the maximum b.h.p. output is most required. In this respect it is unlike a steam engine, which can be made to develop considerably more than its normal torque for short periods, by increasing the cut-off and the steam pressure.

In the case of a gear-driven 'bus of the usual type, in order to provide sufficient torque at starting, it is necessary to introduce a comparatively large gear ratio between the engine and the road wheels. The vehicle is accelerated to a certain speed on this gear, which is then changed for one of a lower ratio, and so on, until three or even four ratio changes have been made to bring the vehicle up to full running speed. Before each gear-change is made, the driving strain must first be taken off the teeth of the gear wheels. This is accomplished by withdrawing a clutch operated by a foot pedal, thus disconnecting the engine from the drive. It can be readily understood that a considerable amount of judgment and skill is required to effect each gear-change without noise or shock.

At starting, the motors demand a large current in order to develop the necessary starting torque; the dynamo supplies this current, but at a very low voltage. As the motors speed up they automatically demand less current, which is supplied by the generator, but at an increased voltage. In other words, the voltage of the generator varies in inverse ratio to the ampere output, therefore the power required to drive it can never exceed a certain predetermined maximum, which is arranged to

Digitized by Google

correspond to the maximum power of the engine. Whatever the current demand may be from the generator, it cannot cause an overload on the engine sufficient to reduce its speed and h.p. output.

Almost as important a feature in this system as the generator is the system of control, which has been reduced to the simplest possible form. By use of the auto-regulating generator series parallel control is rendered unnecessary, excepting for services including unusually steep grades. The auto-generator will supply all the current requisite for starting, accelerating and for climbing ordinary grades, with the motors permanently connected in parallel. The controller proper is therefore reduced to a reversing switch of the simplest form. In order to stop the vehicle, the current is not interrupted at the main controller, but the voltage of the generator is reduced to zero by inserting a high resistance in the generator field, and at the same time reducing the engine speed. This is accomplished in practice by a single foot pedal, which is inter-connected with the engine governor, and a field rheostat, in such a manner that when the pedal is fully depressed the engine is governed to run at about 400 r.p.m., and at the same time all the resistance is inserted in the generator field, which is thus weakened to such an extent that the current ceases to flow to the motors, and the vehicle is stopped without breaking the main circuit. On releasing the pedal, the first movement cuts out the resistance, and the generator volts build up on the load, causing sufficient current to flow to the motors to start the vehicle, which will continue to run slowly, the engine remaining governed at 400 r.p.m. On entirely releasing the pedal, the governor is "held up," allowing the engine speed to at once increase to its normal value, and the vehicle to smoothly and rapidly accelerate to its full speed. To slow in traffic it is merely necessary to more or less depress the pedal, thereby reducing the engine speed, and consequently the generator voltage and the vehicle speed. The 'bus fitted with this system is therefore stopped and started, and the speed controlled by one foot pedal, which can be worked with any degree of suddenness without causing shock at starting, or damage to the engine, or transmission. The same pedal is inter-connected in a simple manner with the lever operating the controller in such a way that it is necessary to first depress the pedal to its full extent before the controller can be operated; this ensures the current being reduced to zero before the main circuit is broken. No sparking can therefore take place at the controller, which can be made without carbon breaks or magnetic blow-outs.

A drawing of an omnibus chassis fitted with this equipment is given in the accompanying figure, from which it will be seen that the motors are placed at the sides of the frame and drive the rear wheels through a double reduction consisting of a worm-gear and a chain.

A LARGE ELECTRIC LIFT

AN interesting elevator installation which has recently been completed at the Hoboken terminal of the Hudson and Manhattan Railway Co.'s tunnels under the Hudson river is described in the *Electric Railway Review*. This elevator is for the purpose of placing in and removing from the tunnels and subway the electrically-equipped passenger-cars which will run in these tunnels. These cars are 48 ft. long over all by 9 ft. wide, and weigh empty 64,000 lb., loaded with passengers 85,000 lb. To raise and lower these cars into and out of the tunnel there has been installed an elevator of 100,000 lb. lifting capacity, with a platform 50 ft. long and 12 ft. wide, weighing 32,000 lb.

To provide for this elevator there was first constructed a wellway, with reinforced concrete walls from the tunnel level to the surface. Upon the side walls of this structure are placed six steel columns supporting a steel girder framing directly over the hoistway, and upon these girders is placed the machine operating the elevator platform. This machine consists of two drum shafts, each 50 ft. long, one placed near each side of the wellway. These drum shafts are at the centre of their length driven by a system of four balanced worm gears, arranged so that the load on all four worm gears is equal under all conditions of platform load. All thrust loads are balanced by the worm shafts, which have right and left hand worms operating the worm gears. These worms and gears run in oil baths in tight casings. The entire system of drum shafts, worm gears, and worm shafts is driven by one 100-h.p. motor placed at the centre of one side of the elevator machine.

The elevator platform is constructed with two longitudinal steel girders, one under each rail, with suitable steel framing to support the suspension sheaves, whereby the platform is suspended from and operated by the elevator machine. The floor of the platform, which is 600 square ft. in area, is covered with diamond pattern steel floor plates. At the sides of the elevator platform, connecting with the machine above, are 32 ¾-in. diameter steel cables, which pass under suspension sheaves below the steel plate floor of the elevator and return to anchorages in the steel overhead structure. By this arrangement one-half the load is suspended directly by the overhead structure, and one-half is suspended from the drums of the elevator machine. In addition to the thirty-two machine cables, the platform is suspended by eight counterweight cables, making a total suspension of the elevator platform and load by 40 ¾-in. diameter steel cables, having a total combined strength of 1,552,000 lb. The counterweights weigh 63,800 lb. total. The machine and cables are so arranged that the elevator platform cannot incline from a horizontal position, wherever the load may be placed upon the elevator platform. Iron frame gates are provided, which close when the elevator platform is not at the landings.

The elevator is controlled electrically by a pilot switch, operated by a hand shipping cable, and the elevator may, at the will of the operator, be run at speeds of 10 to 20 ft. travel per minute, the platform stopping automatically at the track levels. The rise of the elevator from the tunnel track to the surface track is about 30 ft. The elevator platform will be equipped with the third rail conductor, which will be alive only when the platform is at the track levels, and the tunnel cars may be run by their own motors on, off, or across the elevator platform. Provision has been made to hold the elevator platform securely in position while the cars are run upon it.

In addition to the usual service of this elevator in handling cars into and out of the tunnels, it is arranged to be utilised for quickly changing one or both of the motor trucks under a car body. For this purpose the elevator platform travels 3 ft. above the surface tracks, and when in this position blocks are thrown in place under the car body, the truck connections are released, and as the elevator platform descends the car body remains supported upon the blocks while the trucks descend on the elevator platform. New trucks may in a similar manner be placed under the car body. This operation permits the quick interchange of car bodies and trucks when either may require repairs.

This elevator is now in uninterrupted operation, handling rails, ballast, and other tunnel equipment material. It provides the only means of access of the cars into and out of the tunnel. The construction of the elevator is fireproof throughout. While the elevator was installed for a lifting capacity of 50 tons, it has handled loads of 65 tons.

Electrical Engineers Volunteers.—The undermentioned second lieutenants have been promoted lieutenants in the London division: G. W. C. Kaye, S. W. Humphery. In the Severn division, Lieutenant-Colonel J. A. Hughes is granted the honorary rank of Colonel.

Traction Subways in New York.—The Public Service Commission finally approved, on February 4th, the plans for the Broadway-Lexington Avenue subway. The line will begin at the Battery, continue under Church and Vesey Streets to Broadway, and then under Broadway and Lexington Avenue to the Bronx side of the Harlem, where it will branch into two spurs, one to Woodlawn Cemetery, and the other to Pelham Bay Park. According to the *Street Railway Journal* (New York) the estimated cost of the road and a connecting-link across town under Canal Street is $67,000,000.

Accumulator Manufacturers' Dispute.—In the Court of Appeal on Tuesday, before Lord Justice Vaughan Williams, Lord Justice Farwell, and Lord Justice Kennedy, the case of the United Motor Industries, Ltd. *v.* C. A. Vandervell & Co. (see ELECTRICAL ENGINEERING, Vol. II., page 108) was heard. It will be remembered that the plaintiffs at one time had exclusive rights of sale of an ignition accumulator, known as the "Castle" accumulator, manufactured by the defendants, and the question to be settled referred to the right of the defendants to continue to use the name "Castle" after the agreement had terminated for cells of their manufacture not sold by the plaintiffs. The appeal was from the judgment of Mr. Justice Walton, who had granted the plaintiffs' judgment for one farthing damages, with costs, except as to two-thirds of the costs of the trial. Mr. Justice Vaughan, in giving judgment, said that the mere smallness of damages was not a good cause for depriving a successful litigant of the costs of the issues on which he had succeeded. He held that the appeal must be allowed. Mr. Justice Farwell agreed, and said that there was no good cause for departing from the general rule. Lord Justice Kennedy dissented, and thought that the Court of Appeal had no right to alter the former decision. The appeal was allowed with costs by the majority of the court.

SINGLE-PHASE AND THREE-PHASE LOCOMOTIVES: A COMPARISON

REFERENCE was made in ELECTRICAL ENGINEERING, Vol. II., p. 366, to the new 15-cycle single-phase electric locomotive built for the Pennsylvania Railroad for test purposes. The periodicity adopted—15 cycles—has been repeatedly put forward in recent discussions, as the most favourable as regards the weight and properties of the electrical equipment of the rolling stock generally, and, according to many experts, is especially desirable for single-phase motors, rather than the hitherto universally accepted periodicity of 25 cycles. Fifteen cycles is also the periodicity in use on the large three-phase railway lines of Europe, the Valtellina and the Simplon lines, and is that to be used for the Giovi & Savona-San Giuseppe lines, just under construction. The following comparison of the records attained by this single-phase locomotive and those on the New Haven road, with the results obtained with three-phase locomotives, in an article by Bela Valatin, in the *Street Railway Journal*, is of interest.

The latter, which were described in full in ELECTRICAL ENGINEERING, Vol. I., p. 1005, are now built with three ranges of speed. The 8-pole motor of a locomotive of this type, built by the Ganz Electric Co., for the Italian State Railways, has a capacity, on one hour rating, of 1,500 h.p., at a weight of 13·4 tons (metric), and at 220 r.p.m. While building new locomotives of the same type, the manufacturers have recently found it possible, through some changes in the design, to increase the rating of the motors by 20 per cent. to 1,800 h.p., while the external dimensions and the speed of the motor remain unaltered. Another 8-pole motor of similar construction, designed by the Ganz Electric Co., developing 1,100 h.p. on the one hour rating at 3,000 volts, 15 cycles, and 220 r.p.m., weighs 10 metric tons. Neither of these motors has forced draft.

This last motor seems suitable for a comparison with the single-phase motor of the Pennsylvania locomotive, since neither the weights, nor the speeds of the two motors differ materially. The capacity on the one hour rating of each motor of the Pennsylvania locomotive is stated to be 500 h.p., the rated drawbar-pull is given at 14,700 lb., and the diameter of the drivers is 72 inches. From these data the speed of the motor must be 236 r.p.m. The chief data of the two motors are then, as shown in Table I., where the weight factor is :—

$$\left(\frac{G \times n}{2200 \times 100 \times \text{HP}}\right)$$

Table I.

	Single-phase motor.	Three-phase motor.
Rated capacity in horse-power	500	1,100
Weights, pounds, G	19,500	22,000
Revolutions per minute, n	236	220
Weight factor	42	20

From this table it appears that the weight factor of the single-phase motor is more than double that of the corresponding three-phase motor; that is to say, the three-phase motor will develop more than double the power of the single-phase motor at the same weight and number of revolutions.

Very interesting results are also reached if we consider the whole locomotive. The accompanying diagram below was made for this purpose. To confine the comparison to construction actually carried out, the type of locomtive represented by the Italian model previously mentioned has been adopted. The mechanical part of the locomotive would be changed only in so far as the wheel diameter would have to be increased to 77 in., so that the speed of the locomotive might be the same as that of the Pennsylvania locomotive at the rated capacity. The two motors are the 8-pole 1,100 h.p. three-phase motors above described, and may be run at half their standard speed in concatenation, in which case one of the motors has to be commutated to low-tension in the same manner as the 12-pole motor of the three-speed locomotive.

The weight of the locomotive, as actually carried out, was 62 metric tons. In consequence of the larger drivers the mechanical part of the locomotive proposed for comparison would be increased by about 3 tons, from 30 to 33 tons, metric. The weight of the motors themselves would be only 20 tons, as against 25 tons for the motors of the three-speed locomotive, so that the total weight of the locomotive would be 60 metric tons, equivalent to 66 American tons.

If we allow a departure from the condition that the motors of the two locomotives compared should have the same number of revolutions, and, for three-phase, adopt a 6-pole motor or a 4-pole motor, that is to say, motors of one and one-half times or double the number of revolutions, the weight of the motors decreases quite considerably. At the same time the wheel diameter also increases, and with it the weight of the mechanical part of the locomotive. The locomotive proposed for comparison, therefore, is far from being the most favourable design which might be put forward from the point of view of constructional weight for three-phase currents. On the other hand, with single-phase motors, a reduction of the total weight could hardly be attained through an increase of motor speed and decrease of wheel diameter—provided the gearless arrangement with the motors mounted on the shaft is retained—on account of the large dimensions of the motors, which put a limit to th minimum diameter of the wheels. On the other hand, if an arrangement of driving by cranks and connecting rods should be adopted, as in the three-phase locomotive, great constructional difficulties arise in consequence of the increased distance between axles, the greater difference in the height of axles and shafts, &c.

PLAN AND ELEVATION OF THE THREE-PHASE LOCOMOTIVE FOR ITALIAN STATE RAILWAYS.

Table II. gives the chief data of the two locomotives under comparison :—

Table II.

	Single-phase locomotive.	Three-phase locomotive.
Total weight of locomotive in American tons	140	66
Adhesive weight in tons	100	46
Weight of motors in tons	37	22
Rated capacity of motors in horse-power	2,000	2,200
Tractive effort on the one-hour rating in pounds	14,700	16,170
Length over all in feet	62	41
Speed in miles per hour at rated capacity	50	50

Digitized by Google

From these data it appears that the locomotive of the Pennsylvania Railroad, at an approximately equal capacity, has a weight more than double that of a corresponding three-phase locomotive. Concurrently the hauling power of the locomotive is less than that of the three-phase locomotive, because, to arrive at the paying train-weight, double the amount has to be deducted from the total train-weight for the idle weight of the single-phase locomotive, as for the three-phase one. This is of importance, especially if there are heavy grades on the road. If, for instance, the railroad has a constant grade of 1 per cent., that is to say, one where the motors may not be loaded beyond their rated capacity, the Pennsylvania locomotive will be able to haul 267 American tons, beside its own weight, while the three-phase locomotive will haul 382 tons, beside its own weight, or 43 per cent. more. The speed in both cases is fifty miles per hour. (The train resistance in this calculation has been taken at 16 lb. per ton on the level.) When the long grades of the line are higher than 1 per cent. this ratio becomes yet more unfavourable for single-phase current. For instance, the single-phase locomotive compared, may, on a constant grade of 2 per cent., haul 123 American tons, whereas the three-phase locomotive will haul 212 tons, or 72 per cent. more, or, if the three-phase locomotive exercises only the same tractive effort as the single-phase locomotive considered, 197 tons, or still 60 per cent. more.

Table II. also shows for the single-phase locomotive, a considerably greater weight on drivers, which, on the basis of a coefficient of one-fifth, yields a maximum tractive effort of 40,000 lb. However, if we consider that so high a maximum with a tractive effort, on the one hour rating, of only 14,700 lb., is scarcely needed, and, with other electric locomotives (for instance, large d.c. locomotives), is never called for; if we further consider that three-phase locomotives will give a higher tractive effort for the same adhesive weight than single-phase locomotives, owing to the even character of the torque of the three-phase motor as contrasted with the pulsating torque of the single-phase motor, we shall conclude that this circumstance does not represent a disadvantage of three-phase operation. At the same time it should be noted that it would be easy to design a three-phase locomotive, which, at the same total weight (66 tons), would utilise its entire weight for adhesion, and should the requirements regarding maximum pull be still higher, the weight could be further increased by the addition of ballast weights. Even then the locomotive would weigh only about half as much as the single-phase locomotive considered, while it could, without trouble, develop for a short time the maximum tractive effort required.

The maximum tractive effort of the Pennsylvania locomotive is not so much a consequence of its motor capacity, as of its great construction weight, which is a disadvantage, and cannot be done away with because of the great weight of motors and transformers. It may be said, therefore, that, roughly speaking, half the weight will suffice to turn out a three-phase locomotive of the same, or rather more, power than that of a corresponding single-phase locomotive.

Wireless Telegraphy in Spain.—The wireless telegraph stations of Corunna and Ferrol, which were the property of the newspaper "El Diario Ferrolano," have recently been ceded to the State in exchange for a temporary and gratuitous service to the newspaper in question. The stations will remain open to the use of the public, and will be employed for the instruction of the employees of the wireless telegraph service, who are destined for the stations to be established at strategic points.

The Imperial College of Science.—The acting-secretary of the college has written to the Education Committee of the London County Council, asking for a maintenance grant of £5,000 for the year 1908-9. According to the scheme of 1903, the Council proposed to contribute the sum of £20,000 per annum, provided that land, buildings, and equipment for the proposed additional technological teaching and research, to the value of not less than £500,000, were in use. The acting-secretary states that the governors do not think it necessary that the Council should contribute the full amount of £20,000. The General Purposes Sub-committee of the Education Committee, report that although the governors have a capital of £510,500 at their disposal, only £86,000 is in use—this amount being roughly the value of the new portion of the Royal College of Science building. Until the value of the new buildings and equipment had risen to the stated value of £500,000, the Council were not bound to contribute any sum whatever, but they were prepared to include the sum of £5,000 in the annual estimates, and to actually pay this amount if the Council was satisfied that the additional expenditure on the part of the governors for the development of post-graduate teaching and research for the session 1908-9 amounted to not less than this sum.

THE GENERAL ELECTRIC DINNER

AT the eighteenth annual dinner of the General Electric Co., Ltd., held last Saturday at the Trocadero Restaurant, Mr. GUSTAV BYNG presided over a gathering numbering upwards of 450. After the loyal toasts, the chairman proposed "The Prosperity of Electrical Science and Industry." The success of any company, he said, depended on three main factors: the management, the general state of the industry, and political considerations. Mr. Byng then made appreciative references to the work of Mr. Hirst, the managing director, and of many individual members of the staff. With regard to the state of electrical science and industry, we had a serious rival in gas, but the metallic filament lamp had given a tremendous impetus to the electric lighting industry. The Robertson factories were working hard, and the foundations of a large new factory for metallic filament lamps had been laid at Hammersmith. England would soon be on a level with other countries in this matter. The influence of the third factor was not so favourable to success; the members of the present Government were, he said, opposed to the idea that industrial enterprise should be national. It was the duty of the Government to stand by and assist the manufacturer. He emphasised his own opinion that Free Trade had a bad influence on the industry, and attributed to the present fiscal policy of the Government the disproportionate amount of unskilled as compared with skilled labour.

Colonel R. E. B. CROMPTON (president of the Institution of Electrical Engineers) was the first to respond. He said that he was not one of those who thought that the electrical industry was in its decadence. England was obliged to confine herself to smaller and less showy work than that carried out abroad owing to the lack of water-power, but he thought that in this direction England had done well—nowhere could be found more excellent or better controlled systems of supply; and the average prices for electrical energy, both for lighting and heating, were less than in any other country.

Mr. W. M. MORDEY made some remarks in praise of the energy and enterprise of Mr. Byng and Mr. Hirst. With regard to the work in other countries, he was sure that we had little to learn as to electricity supply. Three years ago he had compared twenty representative towns in England and in Germany, and he had found that three times the number of units were supplied in the English towns at one half the price. He thought that the electricity supply companies would do well to enter into the field offered by small houses taking energy on the prepayment system. Both light and heat must be supplied, however.

Mr. H. HIRST welcomed the guests, and read letters from Sir W. H. Preece and Prof. W. E. Ayrton, who were unable to attend. Sir W. H. Preece was celebrating his 75th birthday in his own family circle, and a telegram of congratulation was despatched from the assembly.

Mr. E. GRANT BURLS and Prof. J. PERRY responded for the guests The latter welcomed the advent of the osmium and tantalum filament lamps, and remarked that the competition with gas had been a good thing for the industry; the invention of the incandescent gas mantle, particularly, had put us on our metal! Electrical engineers, however, should not be too confident about heating; heating by gas was equivalent to paying £6 per ton for coal, but heating by electricity might be said to be equivalent to paying £130 per ton.

The health of the chairman was proposed by Mr. Rashleigh Phipps (president of the Electrical Contractors' Association). In addition to those already mentioned, the guests included the Hon. C. H. Rason (Agent-General for Western Australia) and a large number of well-known consulting engineers, central station engineers, and others connected with electrical engineering. During and after dinner an excellent programme of music was performed, and the evening concluded with an entertainment in which several well-known variety artistes took part.

Temporary Supply at Gillingham.—On Wednesday last week in the King's bench division of the High Court the Lord Chief Justice, Mr. Justice A. T. Lawrence, and Mr. Justice Sutton, sitting as a divisional court, had before them the case of the Mayor, Aldermen, and Burgesses of Gillingham, Kent, *v.* The Kent Electric Power Co., which came before their lordships on a case stated by the arbitrator. In 1905, owing to the destruction by fire of the generating station of the Gillingham Urban District Council, an agreement was entered into with the Kent Electric Power Co. for a temporary supply of electrical energy. This agreement was dated June 6th, 1905, and provided for the current to be metered at the defendants' power station, any difference between the parties concerning the agreement or its construction was to be referred to an arbitrator. A supplemental agreement was later entered into for a continuation of the supply under the original agreement. At the date of this extension agreement, a question arose as to the accuracy of the meter. The point went to arbitration, and the arbitrator, being in doubt as to whether he would be in order in admitting evidence of certain tests of the meter in question, applied to the court for direction. Their Lordships decided that the case should be sent back to the arbitrator for the admission of the evidence referred to.

A NEW SINGLE-PHASE RAILWAY MOTOR

MR. E. F. ALEXANDERSON read a Paper recently before the American Institute of Electrical Engineers describing a new single-phase motor designed for traction purposes. The motor in question, is neither a series nor a repulsion motor in the generally accepted sense, but embodies the best features of both. The windings resemble those of a series motor, and the armature and stator are permanently connected in series. A general diagram of the motor is shown in Fig. 1. The terminal voltage can be selected with greater liberty than in a series motor, but not so arbitrarily as in the case of a repulsion motor. The author designates the motor as a "series repulsion motor" for lack of a better name.

In its performance it resembles the series motors with commutating poles, but several distinct advantages are claimed over the same. Instead of producing a commutating flux locally by coils on the stator, the conductors in the armature are located in such places where the desired flux will naturally exist. This arrangement simplifies the stator winding considerably. The compensating winding of the series motor is replaced by an inducing winding with twice as many turns, and the energy is introduced either in the stator alone or in the stator and rotor together. By this arrangement, as will be explained later, the starting torque is doubled for the same commutation and the same supply of current.

In the compensated repulsion motor the commutating field becomes too strong as soon as the speed appreciably exceeds synchronism, unless special arrangements are made to suppress this field locally. The motor under consideration is not limited by the synchronous speed, as the repulsion motor feature is reduced at the high speeds, and its action follows more closely the performance of a series motor; the number of poles can therefore be selected with the same liberty as in a series motor. This is of great importance for the motor characteristics, particularly in regard to weight and starting torque. Furthermore, no extra set of brushes, nor any series transformer, is required, which makes the motor equally well adapted for direct and alternating current. These being the most important general characteristics of the motor, there are a number of features which are of interest, particularly to the designer.

A theoretical discussion of some length is given in the Paper to demonstrate how the two fundamental conditions for good commutation can be fulfilled in a series repulsion motor at any speed without the aid of commutating poles. Instead of creating a commutating flux artificially in a place where the commutated conductors happen to be, the conductors are located in a place where the correct flux will naturally exist. By controlling the value as well as the phase of the different fluxes as described, perfect commutation can be obtained at any speed. The improvement introduced by the fractional-pitch armature winding is a separate matter and is of the same character as the change from an ordinary direct-current machine to a commutating-pole machine.

The starting of a single-phase motor is materially handicapped by the fact that the alternating nature of the main

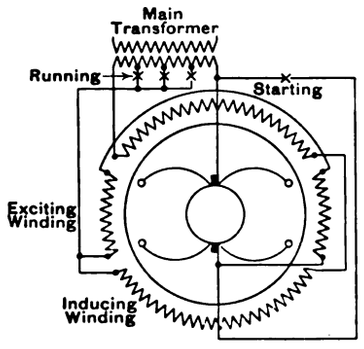

FIG. 1.

field sets up currents in the armature coils which are short-circuited by the brushes. This same difficulty is experienced in all known types of single-phase commutator motors. Although the principle involved is the same in the motor under consideration, the practical result gained by the arrangement employed is a starting torque twice as high as would be possible in a corresponding series motor for the same commutation and the same supply of current.

This double starting torque is obtained by winding the stator with twice as many turns as the armature. The motor starts as a repulsion motor with the armature short-circuited as shown in Fig. 2. The current as it enters the stator has only half the strength of that in the rotor, owing to the ratio of stator to rotor turns. The short-circuiting switch of the rotor carries only half as much current as the rotor itself, because the current in the short-circuited connection is only the difference between the stator and the rotor current. The inducing winding, the field, and the armature are connected permanently in series, but with the connections shown, the field is in series with the stator circuit at starting and with

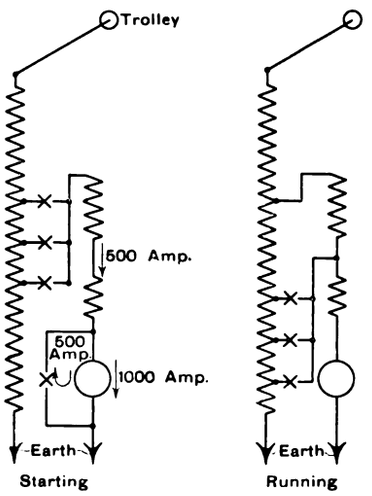

FIG. 2.

the rotor circuit when running. In starting, the rotor carries twice as much current as when running, in order to give the same field strength—in this manner doubling the starting torque. The sparking at starting is quite insignificant up to a certain value of the voltage short-circuited by a brush, but beyond this point the commutation rapidly becomes bad. This critical value is about the same as that which gives a reasonably good commutation in running. In regard to the practical application of the system, it may be mentioned that several four-motor equipments for alternating and direct current have been in operation for some time. The alternating-current control equipment has a total of seven contactors and a reversing switch. This gives four points on the controller which seems quite satisfactory for motor-car operation, though any number of steps can be added to take care of locomotive operating conditions.

The preferred method of control is the one shown in Figs. 2 and 3. In starting, the armature is short-circuited, and the full secondary voltage of the transformer is impressed upon the inducing and exciting windings. The current flowing through the stator continues through the armature, but due to the ratio of turns of inducing winding and armature winding, an additional current of equal strength to the stator current flows through the local circuit of the armature and the short-circuited connection. In the running connection, part of the power is introduced in the stator and part in the rotor, and the field winding carries the same current as the armature; that is, twice the stator current, thus giving a relatively greater field strength than in the starting condition, just as it would be produced by a series-multiple connection of the field winding.

Although the total potential impressed upon the stator and rotor is the same for starting and running, the result of changing the connection so as to transfer the energy input from the stator to the rotor has the effect of increasing the resulting voltage of the motor. This is due to the ratio of transformation between stator and rotor. In this manner a higher speed is obtained by impressing a higher resulting voltage, and the same change of connections makes the motor adapted for a higher speed by changing the ratio of series and repulsion motor action.

The considerations governing the power factor of single-phase motors are then briefly considered, and it is shown that the power-factor of the "series repulsion motor" is practically the same as in a series motor.

The use of resistance leads, which has been so much discussed, has been found to be unnecessary in motors of the

Digitized by Google

type described. Certain motors which have been operated for a considerable time as series motors, and then rewound so as to embody the features described in this paper, have shown an increased life of brushes and commutator up to the standard of good direct-current practice. The improvement in commutation was so great that it was possible at the same time to increase the thickness of the brush and the output of the motor.

In regard to choice of frequency, the series repulsion motor again gives greater liberty. Whereas the starting torque can be doubled on either 15 or 25 cycles, it may be mentioned that a series motor which was almost inoperative at a certain load at 25 cycles, after rewinding, as described, was tested as a series repulsion motor, and found to give excellent commutation at 40 cycles, at the same load. It can therefore be said in general that 25 cycles is entirely satisfactory for all geared motor work; it is preferable in that the combination of motor and transformer weighs less at 25 than at 15 cycles.

Economy of Material.—The motor described can be built in larger capacities than the series motor. The principal reason for this is the inherently good commutation and increased starting torque which make resistance leads unnecessary, thereby eliminating the heat generated by the resistance leads, and also gaining space in the slots, which can be used for copper. Furthermore, it is possible to increase the flux per pole without impairing the commutation.

The author sums up the advantages claimed for the new type of motor as follows:—

(1) Good commutation at all speeds without the use of resistance leads. (2) Larger capacities possible than with the series motor. (3) High tractive effort possible, due to the liberty of selecting the number of poles. (4) Increased starting torque, possible because of the inherent ratio of winding turns, without supplying an increased current from the main transformer. (5) Simplicity of construction. The stator is the same as in the series motor, in fact easier to construct due to the greater liberty of placing the field-winding in slots. The armature is constructed according to standard direct-current practice with the conductors soldered into the commutator bars. (6) Equally well applicable to direct and alternating current.

CATALOGUES AND PAMPHLETS RECEIVED

ALTERNATORS, TRANSFORMERS, METERS.—New leaflets from the Electrical Co. deal with the following subjects:—Specification of revolving field type three-phase alternators with internal or external field; price lists of single-phase oil-insulated transformers, from 1 to 70 kw.; three-phase oil transformers up to 100 kw.; and continuous-current meters for switchboard and traction use.

ARC LAMPS.—A leaflet from the Warner Engineering Co. gives particulars of the "Warner Solio" arc lamp, three forms of which, with decorative metal cases, are illustrated. A polar curve is given showing the excellent distribution of light obtainable with this form of lamp, for which an efficiency of 0·223 watts per mean hemispherical candle-power is claimed. Three sizes, for 8, 10, and 12 amperes respectively, are made, both for continuous and alternating currents.

ARC LAMPS.—A revised price list has been issued by The Foster Arc Lamp & Engineering Co., of Wimbledon, which covers a very considerable range of types of arc lamps and accessories, and also some small transformers for use with metallic filament lamps. The general features of the Foster enclosed arc lamp were described and illustrated in ELECTRICAL ENGINEERING, Vol. II., page 768. Lamps of this description are made in various forms and sizes, and special attention may be called to the inverted reflectors listed. A simple form of hot wire alternating enclosed lamp is also included, in addition to special lamps for photographic purposes, and the Foster flame arc lamp for direct or alternating currents, with the usual inclined carbons and a feed mechanism of the brake type.

CRYSTOPAL TILING.—A pamphlet from Messrs. George Kent, Ltd., points out the advantages of this special form of tiling for the interior of such buildings as generating stations, &c. The white opal glass surface is easily cleaned, and reflects a great amount of light, and the elastic nature of the backing gives the material great strength.

INSTRUMENTS.—A list is to hand from Messrs. Isenthal & Co. composed of several separate sections, conveniently arranged in a cover, and provided with a thumb index for facilitating reference, which covers a considerable range of measuring instruments supplied by this firm. The types included comprise electromagnetic ammeters and voltmeters of switchboard and portable patterns, dead-beat moving coil instruments, and hot-wire instruments. A separate section deals with dynamometer type wattmeters. Flush type and edgewise type and illuminated dial instruments are included, in addition to ordinary patterns, as well as one or two forms of insulation testing apparatus.

METALLIC FILAMENT LAMPS.—A card from the Electrical Co. gives particulars of the "Aegma" metallic filament lamp, which is made in the 25 to 50 c.p. sizes for 100 to 130 volts.

PORTABLE ELECTRIC TOOLS.—A new catalogue of portable electric tools, &c., has been issued by the Consolidated Pneumatic Tool Co., Ltd. A large variety of electric drills are included with self-contained motors. A feature of these machines is the use of a small fan on the motor spindle by which a current of air is drawn through the motor for cooling purposes, so that motors of extremely light weight for their outfit can be employed. The planetary form of reduction gear used also permits of great compactness, and the ball thrust bearings tend to high efficiency. The smaller drills are of the ordinary single armature type, but an ingenious arrangement of two or even three armatures revolving in one field system is adopted in the larger machines. Some of these drills were illustrated in ELECTRICAL ENGINEERING (Vol. II., p. 612) in connection with the recent Engineering and Machinery Exhibition at Olympia. Alternating and continuous current drills are included, and a number of useful accessories are listed, including a special form of feed gear for adapting these drill to rail bonding work. Other tools are portable grinders, buffers, &c., for hand or lathe use, as well as pedestal forms, and a special design of long-necked grinder for internal work. A particularly compact self-contained blower for dusting electrical machinery is listed, and another line of machinery which should be mentioned is simply designed series of electric worm-geared lifting blocks. Other apparatus includes a magnetic separator, which can be employed for separating iron and steel borings and turnings from dirt, and several other purposes, and a submarine arc lamp for the use of divers.

STORAGE BATTERIES.—The D.P. Battery Co. have issued a pamphlet on their well-known storage batteries, printed with three parallel columns in English, Japanese, and French respectively. The Japanese lettering is printed in lines across the page, to read from left to right, in order to correspond with the other two languages, and the prices are given in £ s. d., although Japanese numerals are employed. We notice what appears to be a typographical error in the table of capacities on p. 10, where, in the Japanese column, the second size is given as 140 instead of 240 ampere hours.

TELEGRAPH, TELEPHONE, AND RAILWAY SIGNAL APPARATUS.—A handsome bound catalogue from the Walters Electrical Manufacturing Company at Kensal Road, W., contains particulars of a very complete line of telegraph instruments, including Morse ink writers, full sets of apparatus for single and double current, simplex and duplex, diplex and quadruplex working, sounders, relays, keys, and other apparatus, galvanometers, and testing appliances. A number of patterns of bells, indicators, and pushes are included, and a complete range of lock and block instruments for railway signalling. The telephone section embodies most of the familiar types of wall and table sets for battery and magneto working, small switchboards for private exchanges, and automatic replacement intercommunication telephones. Battery materials of all kinds are included, as well as insulators, line material, and tools.

TRANSFORMERS.—Messrs. Johnson & Phillips, Ltd., have issued a carefully arranged and well illustrated pamphlet describing their series of standard designs for single-phase and three-phase transformers. The air-cooled type are built up to 100 k.v.a. capacity, the oil-self-cooled type up to 400 k.v.a., and oil-insulated water-cooled type up to any size. The cores are of the "butt joint" type, and a damaged coil can be easily replaced. The frame is simple, and is so designed that there are no clamping bolts through the part which carries the magnetic flux. Particulars of performance of this type of transformer, and finally the dimensions and weights for both single-phase and three-phase air and oil cooled transformers are given.

WEIGHING MACHINERY.—The new catalogue of weighing machinery issued by Messrs. Hodgson & Stead, of Manchester, contains illustrated particulars of practically every kind of weighing appliance, ranging from the largest railway weighbridges, down to the smallest scales and balances, including a particularly large selection of platform weighing machines for general purposes.

Sale of Magneto-Igniters.—In the Court of Appeal on Friday before Lord Justice Vaughan Williams, Lord Justice Farnwell, and Lord Justice Kennedy, the case of De la Valette *v.* Riches & Co. was decided. The first claim had been admitted, but defendants (Riches & Co.) had brought a counterclaim for breach of contract, and judgment had been given by Mr. Justice Walton, who had granted defendants £750 damages, but had raised the point as to whether the agreement was enforcible. (*See* ELECTRICAL ENGINEERING, Vol. II., page 193.) Their lordships held that the contract did not come within the Statute of Frauds, and was not enforcable, and accordingly the appeal was allowed.

THE OFFICIAL AUDIT OF ELECTRIC SUPPLY COMPANIES' ACCOUNTS

In November last the Board of Trade issued to electric supply companies a letter, which we reprinted at the time, stating that "they are considering how far it would be possible or expedient to utilise for the purposes of the official audit, the audit conducted on behalf of the shareholders, and so to reduce the amount of work and inconvenience involved by the double audit." This letter has led to protests from a large number of local authorities, who are evidently under the impression that their interests as the potential purchasers of the companies' undertakings are in some way protected by the existing official audit, and would consequently be imperilled if it were dispensed with. The principal ground for this view appears to be that the purchase prices to be paid when the undertakings are eventually acquired by the local authority, will be based upon the companies' capital expenditure, as shown by their books, and that it is therefore necessary that an official audit shall be maintained to prevent improper allocation of expenditure to capital account, or inflated and unnecessary capital expenditure.

There are two principal conditions under which the company undertakings may be purchased by the local authorities, and it is necessary to consider these separately in order to see whether, and to what extent, the official audit could be a protection against over-payment by the purchasers.

The first or general statutory conditions are those provided by Section 2 of the Electric Lighting Act of 1882, which permits the local authority to purchase the undertaking at the appointed time at the fair market value of the lands, works, materials, and plant *at the time of the purchase*, due regard being had to the nature and *then condition* of such buildings, &c., &c., and to *the state of repair* thereof, and to the circumstance that they are in such a position as to be ready for immediate working, and, to their suitability of the same to the purposes of the undertaking, but without any addition in respect of compulsory purchase or of goodwill, or of any profits which may or might have been made, or of any similar considerations. Failing agreement between the parties, the price is to be determined by arbitration, and the section above summarised is a statutory instruction to the arbitrator as to the basis he must take for his award.

There has been no purchase under the section, but it is sufficiently close to the purchase clause (Section 43) of the Tramways Act of 1870, to make it certain that the legal meaning is substantially the same, so far as it has any bearing upon the question of audit of the companies' accounts.

In the first place, the value is the structural value of the works, plant, &c.; at *the time of the purchase*, in their *then* condition, their *then* state of repair, and their suitability to the purposes of the undertaking; this can be determinable only by contemporary evidence, and the capital account of the company during the years of its exploitation could not be admitted as evidence by any arbitrator. This view is supported by the actual working of the Tramways Act purchase clause. In the arbitrations held thereunder, the valuations made by both sides are their estimates of the structural value at the time of purchase. The usual method is to set out the cost of the undertaking as a new structure at the "appointed day," and to depreciate it, according to its age, the ascertained rates of wear and the actual state of repair? Some of the company's plans and books may be accepted, as the bases of "quantities," and it is usual for the experts on both sides to endeavour to "agree quantities," in which process the company's records may be used. Any such use is, however, strictly by consent of the purchaser, who may dispute every detail of the company's "quantities," as well as their valuation, if so disposed.

The very specific instructions laid down by Parliament for the guidance of the arbitrator, do not include his scrutiny of the company's books, and it is submitted that those books and the published accounts derived therefrom, will be entirely immaterial to the awards made; and consequently, that their official audit or non-audit must be equally immaterial.

The other conditions under which the local authorities may purchase electric supply undertakings are, generally, in virtue of agreements to purchase before the expiry of the period at which the compulsory purchase clause becomes applicable. Such an agreement may be made in virtue of Section 3, of the Act of 1883, either when the company is obtaining its Parliamentary powers, when the terms form virtually part of the "price of consent," or it may be made at any time after the granting of the powers. In either case the agreement must have the approval of the Board of Trade.

The terms of such agreements, of which there are many in existence, vary widely, but they are in general so drafted as to provide that the company shall receive, in some form or other, compensation for the prospective profits of the time elapsing between the date of purchase by agreement, and that at which compulsory purchase may occur; and in many cases the compensation is defined as a premium added to the capital properly expended upon the undertaking. There are other cases in which the compensation is defined as a sum sufficient to make up some average dividend upon the capital expended, during the whole period of the company's concession; and in all these cases the company's books will no doubt be relevant, but not conclusive. It is therefore contended that the official audit of the accounts is necessary to prevent improper swelling of the purchase price, but if this view is correct it would put upon the official auditor a much more onerous task than that of audit, no less indeed than an annual valuation of the undertaking in the terms of the purchase agreement. On this basis, clearly, the potential seller and purchaser would necessarily seek to protect their interests before the auditor, exactly as they do before an arbitrator. It hardly seems to need argument to show that such an annual valuation is impracticable, and would be a foolish waste of time and money.

To take a concrete illustration, the case of the Borough of Camberwell may suffice. Here, the Borough may buy the undertaking of the County of London Electric Supply Company, at any time, by paying an amount equal to a sum of £133 for every £100 "properly expended on the undertaking and chargeable to the capital account." "The undertaking" means the company's undertaking within the Borough of Camberwell. The company works this in conjunction with other undertakings, as one business. It has no generating station in Camberwell, but it has, on the other hand, mains passing through Camberwell which supply other districts. Evidently the question of how much capital has been "properly expended and charged to the capital account," in respect to that undertaking is one upon which the seller and the buyer, both in good faith, may differ widely, and one on which neither would be willing to take an official's opinion, unless he were acting judicially *ad hoc*, and heard the parties in a regular way. The Camberwell Borough Council has asked the Board of Trade to set up machinery by which its own representations and the explanations of the company may be duly considered, but does not seem to recognise that it is really asking for an annual valuation, and will probably not wish to pay for such work at the usual rates.

The proposal of the Board of Trade to accept the audit of the shareholders' auditor seems to have been made to relieve the companies of the work and expense of two audits of the same accounts. It is difficult to see how any public interest can suffer from the change. It must be assumed that auditors accepted by the Board of Trade will be professional accountants of undoubted capacity and integrity. The official auditors have no legal power to amend accounts of which they do not approve; they may comment on them, and the spectacle is on record of an official auditor in his comments speaking of items which he has "disallowed" for years in succession, with no effect upon the accounts.

A New Form of Accumulator.—A form of battery, containing some points of novelty, made by the Standard Electric Accumulator Co., of New York, is described in the *Street Railway Journal*. The main feature is the complete enclosure of the active material and its lead electrode in a very thin, strong, and porous box of unglazed pottery. The result is a cell having the same chemical properties as other lead-lead-oxide couples, but very light for its output, since the supporting grids have been replaced by the much lighter earthenware. Moreover, the active material stays permanently in place. The cells are built up on the unit system. Each unit box is about 3½ in. square, and half an inch thick over all. Its sides are porous plates, of which the inner surfaces are reticulated, and the outer faces ribbed. The reticulations strengthen the plates and firmly grip the active material, while the ribs give added strength, and also serve as spacers to hold adjacent boxes far enough apart to permit free circulation of the electrolyte when the cell is in use. When assembled the opposed ribs provide vertical flues in which the acid flows freely. The body of the plate is about 1/32 of an inch thick, and so porous that liquid goes through it almost as through blotting paper, while the pores are so fine as completely to prevent any infiltration of the active materials. In building the battery the reticulated sides of the plates are compactly filled with a paste of lead oxide, and a sheet-lead electrode is placed between two plates. The edges are closed tight, either by flanges on the plates themselves or by edge pieces applied when the cell is assembled. In the larger cells as many unit plates as are necessary are assembled with a single large lead sheet as electrode between the active surfaces, and these composite boxes are assembled with non-conducting backing plates and hard lead bands. The element thus assembled is placed in its electrolyte, "formed" in the ordinary manner, and is then ready for use.

A DYNAMOMETER FOR TESTING AUTOMOBILES

A VERY complete apparatus for carrying out tests of automobiles and making measurements under running conditions of speed draw for full horse power of road wheels, brake power, &c., has been installed by the Automobile Club of America, New York.

The dynamometer, which is described in *The Electrical World* (New York), consists of a moving track upon which cars can be fully tried while remaining stationary and under observation. In 1904, Dr. S. S. Wheeler was requested by the club to design and build a machine for determining accurately the performance of cars of all kinds, and the present machine is the result of several years' attention to this problem. It is an assemblage of power absorbing and measuring instruments, and a large power chart with automatically operated pointers. It absorbs and measures the power so that, at a glance, the speed, tractive effort and horse-power can be clearly seen and read at each instant. The measurements show the power delivered at the ground by the wheels of the automobile. Instead of travelling along, as on a road, the car is held stationary by cables upon the floor with its driving wheels resting upon two large drums which reach up through the floor, and which the engine of the automobile causes to revolve. The revolution of the drums is resisted by a large pendulum hanging below the floor, and attached to the drum shaft, not rigidly, but through a device furnishing a degree of friction which can be varied.

The pendulum, in consequence, swings out from the vertical a distance exactly proportional to the pull exerted by the car upon the drums. The amount of this pull, or tractive effort, is indicated by a pointer attached to the pendulum and reaching above the floor. The indications given by the pendulum are transferred to a ruler travelling across the face of a large chart by a wire cable moved by a small motor, in such manner that with each varying position of the pendulum pointer, the cable is moved to correspond to its new position.

The more difficult operation of measuring accurately the speed of the car, by moving another ruler vertically across the large chart, is accomplished by special apparatus of some novelty.

A cone is revolved by an electric motor at absolutely constant speed. To verify this speed, a bell, attached to the cone shaft, rings at each 100 revolutions, or at intervals of 30 seconds. A wheel or roller, driven by the automobile and, therefore, revolving slowly or fast to correspond, rolls upon the surface of the cone and is pulled, by an independent motor, back and forth between the small and large ends of the cone until it finds the point where it does not slip because that portion of the cone presents the same speed as the roller. This longitudinal adjustment of the roller is transmitted by a wire cable to the speed ruler on the chart, and the power required for moving the ruler is thus made independent of the automobile. In other words, none of the power of the automobile is used in operating the indicators on the chart. The method of speed measurement employed, based upon one element running at a constant speed like a clock, that can be verified, insures great accuracy. The roller, driven by the car if running at 60 miles per hour, must be drawn to a position near the large end of the cone in order to run with the cone. Whereas, if the car drives the roller at only five miles per hour, it must be drawn to a position near the small end of the cone. A system of electric contacts is arranged with a motor to shift the roller automatically until it finds the point where it will roll on the cone without slipping.

The speed and power rulers are thus moved across the chart automatically to correspond with the speed and the tractive effort or pull that the dynamometer shows the car is making.

On the board are painted the horse-power corresponding to each different speed and pull, so that the result at each moment can be read at a glance and without calculations.

The chart can be read easily by the driver of the car. The speed of the car may be read from the chart in miles per hour, minutes per mile, kilometres per hour, &c., by means of the several different scales provided.

All of the measuring apparatus is made reversible so that when running backward the performance of the car may be measured. As a secondary apparatus, a grade meter is provided, operated by the pendulum indicator of the dynamometer. To use the grade meter the clamp is set upon the sliding scale at the point representing the weight of the car. The moving lever then assumes at each moment the angle of inclination of the grade the car would climb (if there were no wind resistance, slipping, &c.), with the effort that the car is then making.

To observe an automobile coasting down hill, either forward or backward, it is necessary merely to start the electric motor on the shaft carrying the two large drums upon which the driving wheels of the automobile rest. The brakes may then be tested, and the wheels or gears or engine may be run free (not run by the power of the automobile), and the relative friction loss of the automobile may be ascertained. The exhaust from the automobile engine is directed into a pipe connected to an electrically driven exhaust fan, so that the test room is free from smoke and obnoxious fumes. The apparatus was built by the Crocker-Wheeler Company.

The Mersey Railway Contract.—On Friday, in the Chancery Division of the High Court, Mr. Justice Eve heard a motion in the action of the British Westinghouse Electric Manufacturing Co., Ltd., v. The Mersey Railway Co. Mr. Stewart Smith, K.C., and Mr. Martelli, appeared for the plaintiffs, and Mr. P. Ogden Laurence, K.C., and Mr. Clauson were for the defendants. Counsel explained that the defendant company had obtained powers to convert its line to electric traction. The plaintiffs, who carried out the work, were to take payment in debenture stock, and were also to find money to redeem certain existing debenture stock. This arrangement was embodied in an agreement dated July 15th, 1901. That agreement recited that there was then outstanding original first debenture stock amounting to £249,276, and that under its new Act of 1900, the defendant company was authorised to create and issue two further amounts of debenture stock of £275,000 and £428,000, making a total of £703,000 debenture stock. The contract price for the work was to be £620,000, payable in 4 per cent. perpetual debenture stock. Therefore on the redemption of the £249,276, the company was entitled to create and issue £703,000 perpetual 4 per cent. debenture stock. The agreement also provided that the Mersey Railway Co. should not issue the difference between the £249,276 and £275,000, or the difference betwen the £620,000 and the £703,000, at a higher rate of interest than 4 per cent., or at a lower price than par, without the previous consent of the plaintiff company in writing. The action was brought for alleged breach of this clause. The reason for the clause was that the company should not flood the market with stock which would spoil the plaintiff company's holding. His lordship inquired if Mr. Smith contended that the clause bound the defendant company for all time. Mr. Smith said he did not know, but he did say that it bound the defendant company so long as the plaintiff company had rights under the contract. The plaintiff had still got some of the debenture stock, and there was a considerable block of the £620,000, namely, £34,000, unissued. The plaintiff company said the work was all completed in June, 1906, but as so often happened in these contracts disputes had occurred. The railway company said that the work was not completed, and that the plaintiff company had been paid all it was entitled to. The parties had been at arbitration on the matter, and a supplementary agreement was entered into on July 19th, 1904, and the defendant company now said that there had been a breach by the plaintiff company of its obligations under the supplementary contract, which released the defendant company from its liability under the original works contract. That was the question that had to be determined. If the defendant company was right, the consequences to the plaintiff company would be very serious, because there was £34,000 stock unissued, and if the fetter under clause 4 of the works contract were removed the defendant company would issue stock at such discount as it pleased. In this way the defendant company could interfere with the large holding of stock held by the plaintiff company, and its friends, and could destroy any market for the plaintiff company's shares by putting blocks of debentures on the market at a lower price. The defendant company, in fact, was trying to force the plaintiff company to at once take up the unissued £34,000 stock. Mr. P. Ogden Laurence, K.C., for the defendant company, argued that no reading of clause 5 warranted the construction that the plaintiff company was to have two months' notice in each year. His lordship, in his judgment, held that the plaintiff company was bound to take over the stock on January 2nd, 1908, and that by the failure to do so the company stood released from the works contract. It was said that the conduct of the company, subsequent to the failure of the plaintiff company to take the shares amounted to a waiver of the consequences, because it did not present the stock. But the obligation was on the plaintiff company to present itself with the money to pay for the stock. The company was, by plaintiff's failure to take the stock on January 2nd, 1908, released from clause 4, and all he could do was to refuse the motion. The motion was accordingly refused ith costs.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

TWO highly interesting articles by Dr. A. E. Tutton, F.R.S., have appeared in the last two numbers of the *Times Engineering Supplement* upon "The Diamond and its Artificial Reproduction." The first article deals mainly with the diamond as it is found naturally occurring, and its properties. It is premised that the diamond is always produced by the crystallising of molten carbon under pressure, and it is presumed that the crystallisation usually took place within molten iron. The blue clay which forms the pipes in which the diamond is found is not the magma in which the crystallisation took place, but the diamonds have been forced up into the clay by volcanic agencies. Recently blocks of one of the original rocks in which crystallisation took place were found in blue clay. These blocks consisted of an eclogite containing large quantities of iron, and small diamonds were actually found within them, thus giving the final proof that such was the original mode of origin of the diamond. Although carborundum and metallic tantalum approach the diamond in hardness, they do not exceed it, and the diamond is still the hardest substance that we know. Although diamond is so hard, it is extremely brittle, and can readily be reduced to a powder by a blow from the hammer. But Sir William Crookes has shown that if it be placed between two hard steel jaws, and an even pressure applied, the jaws can be made to touch each other, the diamond having been embedded into the hard steel as if it were wax. Diamond is, as is well known, an allotropic modification of carbon, and by strongly heating it in an electric arc, can be converted to graphite. Quite recently Parsons and Swinton have shown that by rapid bombardment by means cathode rays, the diamond can be converted into a graphite coke. The current used was about 48 milliamperes at 11,200 volts, and at a temperature of 1,890 C. the diamond swelled up and became converted into this coke. It was left to electric furnace methods to prove on a laboratory scale that the necessary conditions for the production of crystalline carbon in the form of the diamond, are high temperature pressure and slow solidification. High temperature, because it is first of all necessary to liquefy the carbon. It has been found when amorphous carbon and graphite are heated to a temperature of 3,600° in the electric arc, in an atmosphere incapable of chemically acting upon the carbon, that they vaporise without first liquefying, and on cooling condense to form crystals of graphite. Diamond, on the other hand, is first converted into graphite, and then vaporises, and on condensation forms graphite. Now arsenic behaves in a similar manner, but if heated under pressure, it can be liquefied. The conclusion there is, that if carbon is heated to a sufficiently high temperature at a sufficient pressure, and is allowed to cool under pressure, crystalline carbon in the form of diamond will settle out.

In 1896 Moissan showed that by dissolving sugar carbon (the purest form of amorphous carbon) in molten iron, and plunging it into cold water or mercury, great pressure is produced. When pure iron is cooled it contracts regularly like any other metal. But when carboniferous iron is cooled it expands in the act of solidifying. By suddenly quenching iron, a solid layer or crust is produced outside the molten metal. When, therefore, the inside layer commences to solidify, it expands as it solidifies, and thus, as it is encompassed with the solid crust, enormous pressure is exerted. When quite cold the iron was dissolved away by means of acids, and there was left behind minute crystals of diamond. Moissan melted the iron in a carbon crucible with a current of 1,000 amps. at 60 volts, a temperature of between 3,000 and 4,000° C. thus being obtained. Crookes, in 1897, confirmed Moissan's work, and again in 1905 Moissan publihsed a further paper upon the subject. Shortly after Moissan published his work in 1896, Professor Majorana, in Italy, also showed that pressure and high temperature were necessary. He heated a piece of charcoal between two carbon electrodes, and then while incandescent drove it with great force into a hole in a steel block. In 1905 Sir Andrew Noble exploded cordite in closed steel cylinders, a temperature of 5,100° was obtained, and a pressure of 50 tons per square inch. Sir William Crookes examined some of the carbon deposited, and found it to contain minute diamonds. Although electricity has been successful in unravelling nature's secret of manufacturing the diamond, it is not probable that diamonds will ever be manufactured. We have no conception of the enormous forces exerted by nature in the earth's interior, where masses of molten metal and rocks are cooled slowly. And this is really the point, we cannot conduct our experiments upon a sufficiently large scale, and cool slowly enough, to ever expect to obtain large crystals of diamond. It has already been mentioned that carbon exists in three allotropic forms. There is no difficulty in obtaining amorphous carbon or charcoal, but until the introduction of the electric furnace it was not possible to manufacture graphite, but last year, as we mentioned in this article last week, 3,092 tons were manufactured in the electric furnace.

In contradistinction to the results obtained by J. Tafel, who stated that when nitrates were reduced in acid solution with copper cathodes the reduction does not go beyond the hydroxylamine stage, H. E. Patten found that hydroxylamine is reducible with copper cathodes, and he was able to obtain 58·8 per cent of the theoretical yield of ammonia. The electrolyte contained in this case 1·7 per cent. of sulphuric acid. (*Chemiker Zeitung*, 1907, 1,135.) Tafel now replies (*Chemiker Zeitung*, 1908, 135) that his reductions were carried out with a heavy current in 50 per cent. sulphuric acid, and that in such an electrolyte hydroxylamine is not reduced to ammonia. He has, however, repeated the work, using diluted acid, and finds that hydroxylamine is actually reduced when the concentration of the acid in the cell is below a certain minimum. The question is one of interest, the probable explanation is that in dilute solutions the hydrogen is given up with a higher super-tension than in strong solutions.

Electrochemical and Metallurgical Industry of February reports that the Canadian Zinc Co. is making good progress with the completion of its plant. The plant is designed for the electric reduction of zinc, and is being built after the designs of F. T. Snyder. An electric plant is working successfully in Sweden, but this is the first plant to be erected on the American Continent. A large quantity of the lead ore in the Slocan district contains zinc, and the smelters demand a penalty for the zinc content. Consequently, a considerable quantity of the ore cannot be worked owing to this penalty. The establishment of the Canadian Zinc works in Nelson will mean the opening up of many Slocan properties which at present cannot be worked remuneratively.

In the same number of *Electrochemical and Metallurgical Industry*, a Multiple-Voltage Dynamo for Electroplating purposes is described. There are two commutators and two sets of brushes, one on each side of the machine. The commutators are each connected with half of a double winding on the armature. For plating purposes each set of brushes may be connected to a plating tank, so that two separate tanks may be operated from the same machine. Both may be operated independently of the other, since by placing in each circuit an adjustable resistance it is possible to adjust the pressure at the terminals of each tank at will. It is also possible, by connecting the negative brush on the one side of the machine with the positive brush on the other side to connect the two armature windings in series, so that the double voltage is produced at the two free brushes. Suppose, for example, that the machine is built to give normally 5 volts on each side, it is possible to supply any voltage between zero and 5 to two tanks simultaneously and independently by means of the two adjustable resistances. But by connecting in series as just described, it is possible to obtain anything between 5 and 10 volts. By using a single machine in this way, the saving in first cost and floor space is self-evident. The whole of these changes can be made with three switches. One for connecting the two windings of the dynamo in series. When this switch is open there is no connection between the two windings, and the current can be taken off from both sides of the machine independently and fed to two local circuits. One switch in each of the two local circuits is necessary to open and close them independently. These dynamos are built for from 400 to 10,000 amps., and are supplied by the Zucher and Levett and Loeb Co., of New York.

The first award of the Perkin medal has been made to Mr. J. B. F. Herreshoff, the chief scientific adviser to the Nichols Copper Co. The Perkin medal was founded in 1906 in connection with the "coal tar colour" jubilee, and is to be given to an American chemist in recognition for good work done. It is particularly interesting that it should have been given to an "electro-chemist," it also shows the importance which the Americans attach to this comparatively new branch of chemistry.

The Electrochemische Werke, of Berlin, which is in a very flourishing condition, have just declared a dividend of 9 per cent. Their chief works are in Bitterfeld and Rheinfelden, and also at the Chemische Fabrik Griesheim-Electron in Frankfort. They manufacture chlorine, bleaching powder, potassium, hydroxide, sodium hydroxide, potassium carbonate, magnesium, calcium carbide, and metallic calcium; they also manufacture oxalic acid, but not by an electrochemical process.

It is found that small quantities of iron which may dissolve off from the iron electrode, or from impurities in the electrolyte on to the nickel oxide electrode, very considerably affect its capacity. Edison—*American Patent* 876,445 (1907)- states that the addition of 2 per cent. of lithium hydroxide to the electrode very considerably increases the life of the nickel electrode. The electrolyte, beside the lithium hydroxide, is made up of 15 per cent. sodium hydroxide or 21 per cent. of potassium hydroxide.

ELECTRICAL SCIENCE

British and American

On the Positive Electrons in the Sodium Atom.—The greatest part of existing evidence regarding the structure of atoms indicates that the centres of vibration which emit the spectral lines are negatively charged corpuscles. For instance, the Zeeman effect shows that the D lines of sodium are due to the vibrations of negative charges, and the same conclusion is drawn from observations of the magnetic rotation of the plane of polarisation for waves of very nearly the same frequency as the D lines. Band spectra do not show the Zeeman effect, and thus this method is unavailable for investigating the centres of vibration responsible for the bands. R. W. Wood has been working at the problem in another way, and describes his most recent results in the *Philosophical Magazine* for February. White light, plane polarised by passage through a nicol, was passed through heated sodium vapour in a magnetic field, and through a second nicol into a spectroscope. When the nicols are crossed a magnetic rotation spectrum appears in the spectroscope if the vapour is hot and the field on; but because the slightest turn of the analysing nicol restores the full ordinary spectrum, no information as to whether the magnetic rotation is in the positive or negative direction could be directly obtained. When the light emerging from the second nicol in the above experiment was passed through another tube of hot sodium vapour in a magnetic field, and analysed by a third nicol, it was found that rotating this third nicol had no effect. This shows that the spectral lines observed are really narrow bands comprising wave-lengths undergoing gradually differing rotations. The observer, therefore, analysed the light with a pair of Fresnel prisms. The continuous spectrum thus obtained was traversed by a number of horizontal dark bands, which correspond to the points on the slit at which the plane of polarisation is parallel to the plane of extinction of the analysing nicol. Under these circumstances the magnetically rotated line should penetrate the dark band from above or below, according as the rotation is positive or negative. The sodium tube was heated until the fine black absorption lines in the red end of the spectrum appeared distinctly above and below a horizontal dark band due to the Fresnel prisms, then the current was thrown into the magnet. As the field gradually rose, numerous needles of light penetrated the dark band, both from above and below. This, the author concludes, establishes the existence in the sodium atom of both positive and negative electrons.

Self and Mutual Inductance Formulæ.—In the January *Bulletin* of the Washington Bureau of Standards, E. B. Rosa gathers a number of inductance formula, and gives proofs of them. Many of the formulæ are, of course, well-known, and are reproduced merely for convenience of reference; but others are less familiar, and a few are new. One that may be referred to is that of the self-inductance of a "non-inductive" winding of round wires. Suppose the wire arranged as a to-and-fro winding in a plane, the length of each section being l, the distance apart of the adjacent wires, centre to centre, being d, and the wire of radius P, and let $2n$ be the total number of to-and-fro lengths. The author shows that the self-inductance is

$$2l\left[\log\frac{d}{\rho}+\frac{1}{4}-2\log\left(\frac{2\,.\,4\,.\,6\,.\,8\,\ldots\,(n-1)}{1\,.\,3\,.\,5\,.\,7\,\ldots\,(n-2)\sqrt{n}}\right)\right]$$

The term involving n assumes the values 0, 0·1931, 0·2876 0·3522, 0·3804, 0·3961, as $2n$ becomes 2, 4, 6, 10, 14 and 18. The author shows also that the same formula holds for the case of a to-and-fro winding on a circular cylinder, provided that the length of the coil is small compared with its radius.

Continental

A New Electric Furnace.—In the *Comptes Rendus* for February 3rd, L. Clerc and A. Minet describe an electric furnace in which any temperatures from red heat up to the temperature of the arc may be conveniently obtained. When an arc is surrounded by oxide of calcium or magnesium, or other refractory substance, it may be several centimetres in length without consuming more than ordinary power. Keeping the E.M.F. constant at, say, 60 volts, the length may be varied at pleasure by giving the cavity suitable dimensions and the current a certain strength. The sectional area of the cavity containing the electrodes should vary according to a power of the length, which is a little higher than unity, and the current should vary with a power of the sectional area somewhat less than unity. A magnesia or carbon crucible is introduced into the cavity from below. It is mounted on a rod, which can be raised or lowered into any desired position from outside. The crucible contains from 2 to 40 grammes of the substance to be treated, according to its density. The power consumed is one or two kilowatts. The temperature is regulated by bringing the crucible nearer to the arc or further from it. An unusual advantage claimed is that after one electrode has been withdrawn and reinstated, the arc relights without contact.

Flames as Rectifiers.—A. Cathiard showed some time ago that a flame may act as a rectifier for an alternating current of high tension and low intensity. The unidirectional character of the discharge is confirmed by the oscillograph. In a recent communication published in the *Comptes Rendus* for February 3rd, he announces that in this case a true disintegration of the cathode is produced. It is accompanied by the appearance of a very brilliant point on the cathode, whereas the anode is only surrounded by a diffuse violet tuft. If two identical parallel electrodes, say two cylinders, are mounted in the same horizontal plane, and one of them is immersed in a flame containing no solid conductors in suspension, the electrode so immersed is always a cathode. On transferring the flame to the anode, it at once becomes the cathode. The experiment is easily shown with cylindrical rods of homogeneous close-grained carbon, which are specially suitable for anodes.

Magneto-optic Anomalies.—A. Dufour, who recently announced an anomaly in the arc spectrum of calcium fluoride which suggests the existence of positive electrons (see ELECTRICAL ENGINEERING, p. 216, February 6, 1908), carries the matter a stage further in the *Comptes Rendus* of February 3rd. He has found a similar effect (a reversal of the polarisation of the edges of bands in the magnetic field) in the arc spectra of other haloid salts, but in none of these salts do *all* the bands show the effect. The author gives the following tables, in which the figures represent the wave-length of the sharp edge of such band, that the abnormal and normal polarisations are indicated by the letters A and N respectively:—

CaF_2	603A	605A	606N	
SrF_2	651A	653A	660(?)N	
BaF_2	495A	499A	500N	
$CaCl_2$	618A	619A	621N	
$SrCl_2$	635A	636A	661A	674N
$BaCl_2$	514A			

It will be noticed that the abnormal effects all tend towards the shorter wave-lengths. It is significant that this effect is only observed in compounds, though whether these are maintained at the temperature of the arc seems more than doubtful.

Oxford Tramway Arbitration. The point of law raised before the arbitration at the commencement of the Oxford tramway arbitration proceedings came before the Lord Chief Justice, Mr. Justice A. T. Lawrence and Mr. Justice Sutton on Friday. We gave full particulars of the point in question in ELECTRICAL ENGINEERING, Vol. I., page 122. Briefly, the facts are as follows:—The National Electric Construction Co. having obtained Parliamentary powers in co-operation with the Oxford Corporation for the conversion of the existing horse tramways to electric traction, agreed to purchase the latter undertaking under the terms of an agreement between the Corporation and the existing Oxford Tramways Co., the purchase to take place as from December 31st, 1906, which was in advance of the statutory period. The exact price to be paid was to be determined by arbitration. These arbitration proceedings commenced in July last, but at the very outset the difficulty arose which has just been settled by the Court. The agreement between the Oxford Corporation and the existing company is dated December 14th, 1906, and it lays down that the purchase shall take place under Section 44 of the Tramways Act of 1870. It will be remembered that Section 43 of the Tramways Act is the clause under which a local authority may purchase, the price excluding any consideration for goodwill. Clause 44 lays it down that the owners of the tramway undertaking may sell to any body or persons as distinct from the local authority. Mr. Balfour Browne, K.C., for the Oxford Tramway Co., intimated at the arbitration his intention of proceeding on the basis that the purchase was to take place upon going-concern terms, inasmuch as the agreement contained the words, "the then value" of the undertaking. Mr. Hutchinson, for the National Electric Construction Co., argued that Clause 44 of the Tramways Act of 1870 is governed by Clause 43, and that therefore the purchase should take place on the basis of the then value, exclusive of any provision for goodwill or future profits. In giving judgment, the Lord Chief Justice said that, in his opinion, the case was too clear for argument. The agreement stated that the Corporation would "purchase the said undertaking of the said company in pursuance of and in the manner provided by Section 44 of the said Act. And whereas it has been agreed between the company and the Council that the company shall sell and the Council shall purchase the said undertaking upon terms of paying the then value thereof, as provided by Section 43 of the Tramways Act, 1870," and later, quite consistently, "in respect of the tramway as on December 31st, 1906, the standard value for the undertaking is to be the same as in Section 43." The decision, therefore, must be in favour of the Oxford Corporation, and as there was a question in the Special Case which asked the opinion of the Court on the matter of costs, he was quite clearly of opinion that the Corporation of Oxford ought to have the costs of this appeal. Mr. Justice A. T. Lawrence and Mr. Justice Sutton concurred.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 13th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

1,197, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) Boron is purified and rendered a conductor by heating it to a high temperature in a vacuum. It is then fused, powdered up, and finally compressed, with or without a binding material, into the required shape. Four claims, one figure.

1,356, GANZ & CO. EISENGIESSEREI UND MASCHINENFABRIKS AKT. GES. A device for regulating the pressure of alternating current generators. A resistance with a positive temperature coefficient is placed in the field circuit of the exciting machine. This resistance is also in the secondary circuit of a pressure transformer, and, further, another alternating current from the secondary of a current or series transformer is led in at equipotential points in the secondary winding of the said pressure transformer, which current is opposed to that of the pressure transformer. The resultant current, which heats the resistance, decreases in value with increasing load or diminishing power-factor. The resistance cools, decreases in value, and the excitation is increased. Further improvements for rendering the whole more sensitive are described. Seven claims, four figures.

1,759, RAYMOND-BARKER & AMALGAMATED RADIO-TELEGRAPH CO. Radio-telegraphy with undamped oscillations of two or more different wave-lengths and signals of equal time value. This system is particularly adapted for telephonic reception, as two-tone signals are more distinctive than long and short single-tone signals. Receiving apparatus for audible or visible signals for the same system is described. Three claims, eight figures.

2,459, MILES WALKER. As the voltage between adjacent commutator bars of armatures of high speed dynamos is sometimes very high, intermediate bars, which are connected to points on an auxiliary ring or drum winding intermediate in potential between the potentials of the two adjacent main bars, are inserted between the main bars. If the auxiliary winding is a drum winding, it can extend to half the length of the core only, and the end connections are then arranged in a duct in the middle of the core. The auxiliary winding is placed in the same slots as the main winding. Three claims, seven figures.

4,182, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) A protective device for D.C. or A.C. circuits, which will operate to open the circuit upon either an overload or a reversal of current. The device is arranged with a time limit of the bellows type, which is inoperative on an excessive overload or a reversal of energy. A pivoted armature provided with a series winding is moved by a field-magnet provided with a differential shunt and series winding, the series overpowering the shunt on overload. The device will operate even if the voltage of the circuit falls to zero. Five claims, three figures.

5,575, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) An improved method of manufacture of tungsten filaments for electric lamps. The filament, consisting of a compressed mass of cadmium amalgam and powdered tungsten, is first heated in a vacuum furnace, which drives off the mercury, leaving a strong filament. The cadmium is then volatilised by passing current through the filament in a vacuum. Three claims, four figures.

6,242, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) To obtain a higher voltage than the normal, from a mercury-vapour rectifying device, two auxiliary anodes are provided which can be connected to terminals on the secondary of the transformer, which include extra turns, an increased voltage on either side of the neutral connection being applied by this means. Three claims, one figure.

10,007, SIEMENS BROS. DYNAMO WORKS & POYNDER. In order to run an asynchronous motor at a reduced speed economically, the rotor winding of the same feeds into the stator winding of an auxiliary motor, to which is coupled another asynchronous machine. The latter has a larger number of stator poles than the former. The rotors of both machines are of the ordinary short-circuited type. The stator winding of the second asynchronous machine is connected to the supply mains. The energy transmitted by induction to the rotor of the main motor, and ordinarily wasted in resistances, is thus converted to the frequency of the supply and partly recovered. The speed varies only slightly with the load, and by inserting a variable-speed gear between the two auxiliary machines, several working speeds can be obtained. Five claims, one figure.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Names in brackets indicate communicators of inventions from abroad.

Summaries of the more important of these patents will appear in our next issue.

1906 Patents

24,252, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*). Manufacture of incandescing bodies for electric lamps.

24,253, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitats Ges.*). Electric lamps having incandescing bodies of refractory metal.

1907 Patents

1,947, HANSEL. Electrically-operated installation for forwarding postal letters.

1,963, LOEBL & BRITISH EVER-READY ELECTRICAL CO. Electrical switches.

2,132, FLETTNER & FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Controlling motors from a distance.

2,165, ST. JERNBERG. Winding apparatus with variable loads.

2,283, MUIRHEAD. Coherers for wireless telegraphy.

2,381, PARSONS, WILSON, & FORD. Blading for turbines.

2,413, BROWN. Electrical block signalling system.

2,416, SUMPNER. Alternating current instruments.

2,417, CHAMBERS & BENNETT. Electrical switches for internal-combustion engines.

2,509, HUMPHREY. Ignition of internal-combustion engines.

3,116, CUNNINGTON. Electric heaters for bedding and clothing.

3,739, LANCASHIRE DYNAMO & MOTOR CO., WARBURTON, & KELSALL. Method of equalising the power supplied to electric motors.

4,564, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Incandescing bodies for electric lamps.

4,706, HOWORTH (*Akt.-Ges., Brown, Boveri & Cie.*). Single-phase alternating current motors.

4,742, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Alternating current motors.

5,037, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Methods of regulating lighting systems.

5,050, ROSS. Ignition system for explosion engines.

7,883, NAUJOKS, NAUJOKS, & GOEPPERT. Electrically-controlled elevators.

8,138, BERRY, SKINNER, & MARKHAM. Protected fuses.

8,874, HAHN. Alternating current vapour apparatus.

9,965, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Electrically-operated signals for railways.

14,725, SIEMENS BROS. DYNAMO WORKS (*Siemens Schuckertwerke Ges.*). Electrical potential regulators or speed-controlling devices.

14,765, SIMMS MANUFACTURING CO. & ALTREE. Ignition devices for internal-combustion engines.

15,009, FELTEN & GUILLEAUME-LAHMEYERWERKE AKT.-GES. Alternating current electro-magnets.

15,442, CONRAD. Voltage regulation of generators.

16,745, LE MANQUAIS. Electric junction boxes.

16,854, TARDIEU. Telephonic apparatus.

17,455, DEUTSCHE TELEPHONWERKE GES. Signalling apparatus.

17,617, CARTER. Coin-controlled pay station for telephones.

18,152, STONE. Apparatus for determining the direction of space telegraph signals.

18,868, KWAPIL & BIHN. Electro-magnetic make and break ignition devices for explosion engines.

19,805, WACKERMANN. Device for transferring drawings and manuscripts to a distance by electricity.

21,966, CHISWELL. Adjustable holder for telephones.

22,638, SMITH. Winding of phonopore and like induction coils.

27,541, PAULI. Electric incandescent filament lamps.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patents

11,979, DEUTSCHE BECK-BOGENLAMPEN GES. Supported carbon for arc lamps.

12,633, GALLETTI. Methods of producing electric oscillations.

12,636, GALLETTI. Wireless telegraphy.

1908 Patents

412, STEYNIS & CHAUMUT. Ozoniser.

1,427, DE FOREST. Space telegraphy.

1,532, SIEMENS & HALSKE AKT.-GES. Electric signalling.

1,615, BELIN. Apparatus for reproducing graphic documents at a distance.

1,773, ALEXANDERSON. Motor control.

LOCAL NOTES

BALLYSHANNON: *Electric Lighting.*—The Council's permission has been given to Mr. J. S. Myles for the erection of an electric lighting works, subject to public rights being secured.

BELFAST: *Tramway Employees Wages.*—The Tramways Committee has had an application from the tramway men's union, asking for an advance in the present scale of wages for motor men and conductors, and fixing a maximum of 7d. per hour, to be reached after three years' service. In October last the Corporation voluntarily agreed that all conductors and motor men should receive a maximum pay of 6½d. per hour after three years' service, instead of after six years, as at present, such scale to come into operation in April, 1908. This concession on the part of the Corporation will entail an additional cost of £1,300 per annum, and in view of this fact, it has been decided not to re-open the question with the tramway men's union.

Cavehill and Whitewell Tramways Bill.—The London correspondent of the *Belfast News Letter* stated that on Thursday night Mr. Devlin, the Nationalist M.P. for Belfast (West), issued the following statement in the lobby of the House of Commons:—"Mr. Joseph Devlin, M.P., is willing, in the interests of the 70,000 ratepayers who are opposed to the Bill promoted by the Belfast Corporation for the purchase of the Cavehill and Whitewell Tramways, to agree to the passage of the measure provided the purchase price is reduced to £46,000, with the recreation grounds at Glengormley thrown in free. Mr. Devlin hopes by this arrangement to save the ratepayers £30,000 or £40,000. If the compromise is not agreed to, there is not the slightest chance of the Bill being passed, as it will receive vigorous opposition from Mr. Devlin, as the representative of three-fourths of the ratepayers who are opposed to it."

BIRMINGHAM: *Electrical Contractors' Dinner.*—The first dinner of the Midland Branch of the Electrical Contractors' Association was held on Friday. The chair was taken by Mr. F. Brown, and among those present was Dr. Gisbert Kapp, who proposed the toast of the "Electrical Industry."

BOURNEMOUTH: *Tramway Accounts.*—A report has been presented by the Joint Finance and Tramways Committee, in which the auditor states he cannot find that the accounts of the tramways department are in any way subject to examination or check by the Borough Accountant. He urges that all accounts should be subject to some systematic examination in the Accounts Department independent of any examination in the department which is responsible for the expenditure. The accumulated revenue on the Council's tramway undertaking amounted on March 31st, 1907, to £24,999, and the auditor thinks that the time has now arrived when the treatment of these monies, by the establishment of a reserve fund, should receive the attention of the Council. In dealing with this report, the Committee recommend that the Borough Accountant be instructed to report as to what would be involved by the adoption of a simple and efficient checking system in connection with the tramway accounts by his department. With regard to dealing with the accumulated revenue, the Committee are of the opinion that it is not advisable to establish a reserve fund as anticipated at present, having regard to the restrictions to which the Council would be subject in the future application of the accumulated profits if the same were now definitely allocated as recommended.

BLACKROCK: *Dublin and Central Ireland Electric Power Bill.*—This Bill was under consideration by the Urban District Council on Friday, when it was decided to present an objection against the Bill as a precautionary measure. At the same time the Town Clerk, in bringing the matter before the Council, stated that the Bill seemed to be one of the most important measures towards the development of the industrial resources of Ireland, and if it became law, the works which it was proposed to carry out would give a great impetus to manufacturers. The object of the undertaking was primarily to generate and supply cheap electric power to local authorities and other large consumers throughout the city and county of Dublin, and for this purpose to work the extensive series of peat bogs known as the "Bog of Allen." It would afford practically an inexhaustible supply of peat, from which it was proposed to manufacture gas for the purpose of generating electrical energy. Instead of subjecting the peat to elaborate drying and manufacturing processes, the peat sods, only partially dried in handling, would be transported to the gas producers, and there converted into gas. In this way peat containing fully 50 per cent. of moisture would be dealt with.

BRADFORD: *Tramway Intercommunication with Leeds.*—At a conference of sub-committees of the Leeds and Bradford Tramways Committees, the question of arranging for a permanent through service was discussed at some length, and proposals made which will be brought before the respective tramways committees. It will be remembered that the gauges of the two tramways systems in question are not identical, but through connection has been rendered possible by the extensible gauge truck, invented by Mr. C. J. Spencer, the Bradford City Tramways Manager, and Mr. W. H. Dawson. A description of this mechanism appears in ELECTRICAL ENGINEERING, Vol. I., p. 760.

BRAY: *Electric Lighting and Tramways Scheme.*—A letter has been received by the Rathdown (No. 2) Rural District Council from Messrs. B. Hooper & Co., Greenwich, stating their intention to apply for powers to construct an electric tramway between Bray and Enniskerry, and also for the electric lighting of Enniskerry and district. The scheme has been approved by the Council.

CLACTON: *Opposition to Extension of Works.*—The proposed application to the Local Government Board for sanction to borrow £4,000 for the extension of the electricity undertaking, has called forth an emphatic protest from the Ratepayers' Association, which, at a meeting last week, unanimously passed a resolution calling upon the Council to authorise an independent inquiry into the whole working of the electricity undertaking before any further extensions are made.

DARTFORD: *Light Railway Undertaking.*—The Metropolitan Police have called the attention of the Council to the fact that the cars of the Dartford light railways have become subject to the provisions of the Metropolitan Carriage Act, 1907, and the Order of the Secretary of State made thereunder, dated December 30th, 1907. Messrs. J. G. White & Co., the lessees of the tramway undertaking, are making the necessary arrangements for licensing the cars, drivers, and conductors.

DUBLIN: *Progress of Electrical Undertaking.*—The gross income for the twelve months ending March 31st, 1907, was £44,225, of which £10,736 was credited to the electricity accounts for the cost of public lighting, and the balance, £33,486, was received from private consumers, together with rentals of meters, current supplied to the Corporation offices, and work done for the Corporation, &c. The total expenditure was £22,029, leaving a gross profit of £22,196. From this has to be deducted £216, being amount of accounts written off and interest paid on consumers' deposits, and the balance of £23,000 was devoted to the repayment of principal of loans, and the payment of interest. This leaves a debit balance to be provided for of £1,720 1s. 5d. The total amount of the loans received up to March 31st is £441,747, and of this a total of £78,558 have been repaid. The average cost per unit has been about 1d., whereas in 1903 it was 2½d.

DUNDEE: *Tramway Fares.*—A report has been presented by the Tramways Manager with regard to a proposal to abandon halfpenny fares and adopt 1d. fares as a maximum. The Manager is strongly of the opinion that a 1d. maximum fare should be aimed at and adopted as soon as it is possible to do so without jeopardising the financial position of the undertaking. At present, however, he recommends that no special alteration should be made upon the halfpenny stages.

Electric Lighting Tariff.—Upon the recommendation of the Electrical Engineer, Mr. H. Richardson, the Electricity Committee has decided to abolish the minimum amount for lighting of tenements. It was stated that this regulation had been a source of irritation, whilst the revenue accruing from it only amounted to £150 per annum. The new arrangement will come into force at the beginning of the next financial year.

DUNFERMLINE: *The Electric Lighting Order.*—A special meeting of the Town Council was held on Friday to consider the report by Sir Alexander Kennedy in regard to the proposal to sell the Council's electric lighting Provisional Order to the Fife Electric Power Co., the details of which were given in our last issue. A discussion took place in which the general feeling was that the Council should not dispose of the Order, and a motion to the effect that the Order should be disposed of was defeated by 12 votes to 5. It was ultimately agreed to appoint an engineer to submit estimates as to the cost of working a generating station, and, alternatively, of taking a supply of energy in bulk from the Fife Electric Power Co.

EALING: *The Dolter System.*—As a result of a joint meetin of the Highways, Open Spaces, Tramways and Electricity Supply Committees, the Borough Surveyor and the Electrical Engineer have been instructed to submit an estimate of the cost of constructing the South Ealing tramway on the Dolter system, with a gauge of 3 ft. 6 in., and of the annual cost of maintenance and of working a service of four cars to and fro.

Bulk Supply.—The Electricity Supply Committee reports in favour of making an offer to supply electricity in bulk to the Hanwell Urban District Council in accordance with a scheme proposed by the Borough Electrical Engineer. The Council discussed the matter in private.

EDINBURGH: *Smoke Nuisance.*—A meeting of a sub-committee of the Edinburgh Public Health Committee was held last week, when it was unanimously resolved that the regulations allowing five minutes for the abatement of smoke nuisance from the factory chimneys shall in future be insisted upon. It was stated that this regulation will apply to the electric lighting works, in addition to private factories.

Condensing Water Plant Arrangements.—Mr. F. A. Newington, the Chief Electrical Engineer, reports that the work in connection with the use of sewage water for condensing purposes at the Macdonald Road power station, are now practically completed, and that the plant will be in operation at the beginning of next week.

Digitized by Google

FALKIRK: *Proposed Tramway Extensions.*—The directors of the Falkirk and District Tramway Co. received last week a deputation of the ratepayers of Laurieston, a suburb of Falkirk, urging them to construct the tramways into that district, which were authorised a few years ago. No decision was given by the directors.

FINCHLEY: *Electricity Reserve Fund.*—A resolution instructing the Finance Committee to inquire what the annual amount required for a reserve fund in connection with the electricity undertaking would be, has been considered by the Council, but only the mover supported it, and it was accordingly negatived.

FRASERBURGH: *Electric Lighting.*—Mr. H. Richardson, the Electrical Engineer to the Dundee Town Council, has been retained by the Fraserburgh Town Council in connection with its electric lighting scheme.

GRIMSBY: *Agreement with Tramway Co.*—In connection with the proceedings relating to the incorporation of Cleethorpes with the Borough of Grimsby, the Grimsby Corporation have made an arrangement with the Grimsby Tramway Company in order to dispose of their opposition, by which the rights of the Corporation to purchase the tramways in Grimsby as a going concern in 1910 shall be extinguished in favour of the right to purchase under Section 43 of the Tramways Act in 1921. The tramway company have agreed, as a concession, to certain rearrangements of its fares, and to run certain workmen's cars, but the arrangement does not appear to have met with satisfaction locally.

HALIFAX: *Tramway Undertaking.*—A report has been presented by the Deputy Borough Accountant, dealing with the present financial position of the tramways undertaking. It is stated that the total amount of loans authorised is £685,521, of which £394,275 have been expended, namely, £255,149 on permanent way; £38,707 on electrical equipment; £60,000 on cars, and £29,518 on buildings and fixtures. The report also points out that since 1905, when the last two cars were purchased, the cost of repairs has increased considerably, and for the year 1907 amounted to £5,504, or 9·15 per cent. of the total cost. An important part of the report referred to the condition of the permanent way. It is pointed out that the cost of repairing the track during the last six years has been fairly low compared with the capital expenditure, but the time is at hand when an immediate expenditure of some thousands of pounds will be necessary to keep the track in good running order. In connection with the price which should be charged to the Tramways Committee for electrical energy, the report states that this should be 0·87d. instead of 1½d., as at present. As the result of consultations between the tramway manager and the Borough Electrical Engineer, the following list of years as the life of the various portions of the tramways undertaking has been arrived at:—Buildings and fixtures, 30 years; track and bonding, 15 years; cars and equipment, 15 years; overhead equipment, 15 years; tools and plant, 10 years.

KEIGHLEY: *Tramway Revenue.*—At the meeting of the tramway committee on Thursday, it was stated that it was not proposed to ask for any assistance from the rates in respect of the tramway undertaking for the year ending March 31st, 1909. Already they had received £280 more revenue since July than in the corresponding period, and it was probable that for the full year there would be a net surplus of £500 or £600, in addition to the unused grant of £400 from the rates, which would leave about £1,000 to be carried to a renewals fund.

LANCASHIRE: *New Tramway Scheme.*—A project is projected for constructing a tramway from Horwich through Chorley to Preston, a distance of 13 or 14 miles. A Manchester firm of solicitors have written to the Bolton Electricity Committee asking what price the committee would charge for electricity to be supplied in bulk for the purposes of the tramway. The Bolton Electricity Committee have the matter under consideration.

LIVERPOOL: *Electric Lighting and Tramway Accounts.*—The total income of the electric lighting undertaking for the past year amounts to £274,105, and, deducting generation and distribution costs, there is a balance of £158,449. After making allowance for the sinking fund, reserve and renewal fund, there is a surplus of £27,500, which it is proposed to transfer to the borough funds.

The tramway revenue amounts to £598,364, and the gross balance is £199,631. After deducting capital charges, &c., there is a surplus of £27,793, which it is also proposed to transfer to the borough funds.

LOWESTOFT: *Supply in Oulton Broad.*—As the Oulton Broad Urban District Council is opposing the Corporation's application for a Provisional Order for that district, the question was raised at the last meeting as to whether they should abandon this project. After some discussion, however, it was decided to go forward with the application.

LONDON: *London County Council.*—At the meeting on Tuesday expenditure amounting to £7,000 was authorised in order to carry out preliminary works in connection with electrification of the Nine Elms Lane to East Hill, Wandsworth, tramways.

A supplemental vote of £2,000 was passed in respect of the construction of the Embankment tramways. The additional expenditure is mainly due to the cost of alterations required to the carriage way and riverside footway having been considerably greater than was expected.

The Chairman of the Highways Committee, in reply to a question, said that, although the matter of approaching the City Corporation with a view to the trams being carried over Southwark Bridge had not come definitely before the committee, the Council's engineer had been in communication with the City engineer on the subject.

School Lighting.—The Council has approved a proposal to light the extension to the School of Building, Brixton, by means of electricity. Inverted arc lamps will be used in the workships, class-rooms, &c., and incandescent electric lighting in the rest of the building. The cost, exclusive of motors, is estimated at £1,670. Electricity will also be used at the new secondary schools at Dawes Road, Fulham, and Hortensia Road, Chelsea, at an estimated cost of £475 and £492 respectively. In the case of the Fulham School the Borough Council declined to quote a lower price than 3½d. for energy, but they have agreed to bring the service into the school free of charge in a duct provided by the County Council. The Chelsea Electricity Supply Co. will supply current to the Hortensia Road school at a reduced price of 5d. per unit instead of 5½d. In consequence of the marked success of the metallic filament lamps installed at the London Day Training College, these lamps will be used in the new schools.

Progress with the G.B. Surface Contact System.—The track work in connection with the conversion of the Mile End Road tramway to the G.B. surface contact system has been completed by the contractors, Messrs. Dick, Kerr & Co. A service of horse cars is now being run pending the arrival of new cars.

Bermondsey: Franco-British Exhibition.—The Electricity Committee has taken no action with regard to a suggestion of the Associated Municipal Electrical Engineers (Greater London) that the municipal electric supply authorities of London should make a collective exhibition or demonstration of electricity at the Franco-British Exhibition.

Camberwell: Purchase of Electric Lighting Co.—At the last meeting of the Borough Council, a resolution was on the agenda stating that in view of the expert evidence in possession of the Council, that the "option" of the Borough Council to purchase the Electric Lighting Co. was of the estimated value of £40,889, the Council should authorise the Town Clerk to open up negotiations with the company with the object of ascertaining what prospect there was of selling this valuable "option." After a short discussion, the motion was rejected.

City of London Street Boxes.—At the Court of Common Council on Wednesday, a question was asked with regard to explosions in electric lighting street boxes. The Chairman of the Streets Committee stated that only three small accidents from this cause had taken place in the City of London during the past two years, although there were about 9,000 street boxes in the city. They were so carefully attended to by the electric lighting companies, that he saw no need for proposing further regulations regarding them.

Hammersmith: Street Lighting.—The Electric Lighting Committee have had under consideration the question of alterations to the lighting system in Queen Street, the Broadway, Shepherd's Bush Road, and Shepherd's Bush Green, rendered necessary or desirable owing to the construction of the Hammersmith to Harlesden tramways. The engineer has reported that he considers that lighting will be very seriously interfered with if the present central arc lamp standards be removed. He suggests the fixing of lamps alternatively in the tramway standards, which course will require the addition of three arc lamps in order to obtain the same equal distribution of light, and which will cost the Council an additional £20 per annum each lamp. As lighting must be maintained during the progress of alterations, it will be almost impossible to carry out the work by contract, and it must be done by day. The committee has agreed to this suggestion, and has resolved that it be a condition subject to which the Council approves of the L.C.C.'s suggestions for fixing the posts and wires in connection with the tramways, that such alterations and additions to the lighting system should be carried out by the Hammersmith Council at the cost of the London County Council.

Hampstead: Electricity Estimates.—The estimates for the year ending March 31st, 1909, of the Electric Lighting Committee show an income of £65,417, and a total expenditure of £62,998, leaving a surplus of £2,419, which will permit, it is expected, of a transfer equal to a halfpenny in the £ in aid of the general rates. The expenditure estimate for the year ending March 31st, 1908, was £62,645, and it is now anticipated that the actual expenditure will be £63,635. The receipts for the same period were estimated at £67,817, but the actual amount is now only expected to realise £64,093. The falling-off in the receipts from the estimate was in the sale of current to private consumers £58,700 (as against the estimate of £60,500) and in the rental of meters £2,020 (as against the estimate of £4,050).

Hackney: Road Widenings.—The Council has decided to contribute £17,000 towards the widening of Mare Street and Clapton High Road in connection with the conversion to electric

Digitized by Google

traction of the tramways from Whitechapel Road to Stamford Hill.

Metropolitan Water Board: Telephone Wayleaves.—The Metropolitan Water Board has adopted an agreement with the National Telephone Company, whereby the acknowledgments paid by the company for easements for the erection of telephone poles, standards, and brackets, and the fixing of wires and stays on the Board's property shall be uniform throughout all districts. The present income of the Board by means of charges to the company is £224 per annum, and under the new scale this will be increased by a net sum of £48 per annum. The scheme is to operate as from January 1st last. The Board have also agreed to enter into an agreement with the Postmaster-General that all wayleaves existing on August 28th, 1907 (the date when the Board's Various Powers Act came into force), shall be paid for on the old scale down to that date, and thereafter allowed to continue under the terms of the new statute, which empowers the Postmaster-General to erect and maintain telegraph wires upon the Board's land.

LYTHAM: *The Electric Lighting Co.*—The Lytham Electric Lighting Co. is in negotiation for a site for their works.

MALVERN: *Electrical Exhibition.*—An electrical exhibition, organised by the municipal electrical department, was concluded last week, and we are informed by Mr. Rendell Baker that it has done excellent service in the way of picking up new consumers.

NEATH: *The Electric Lighting Scheme.*—A ratepayers' meeting last week passed a resolution that the District Council should abandon its proposed electric lighting scheme.

RICHMOND: *Tramway Matters.*—Negotiations have been going on between the Corporation and the London United Tramways Co. in regard to the type of car to be used upon the tramway over Kew Bridge. The Council require smaller cars than those in use on other parts of the company's system, but to this the company raise objections. After some discussion, a resolution has been passed informing the company that the type of car would be discussed should the Bill be passed. With reference to the West London, Barnes, and Richmond Tramways Bill, the Corporation is willing not to oppose this upon certain conditions. These include a purchase clause specifying 45 years instead of 60 years, as proposed by the Bill, and the deposit with the Corporation of £300 as security for the repair and maintenance of the roadways and track. In reference to the Corporation's dispute with the Richmond (Surrey) Electric Light & Power Co., it was suggested that an agreement might be come to on the basis of a reduced scale of charges in the district, and the removal of the chimney at the electricity works as soon as a supply in bulk was received from an outside source, in order to do away with the complaints as to vibration at the works.

SHANGHAI: *Completion of Tramway System.*—The Shanghai Electric Construction Co. announce that the construction and equipment of the electric tramway system is now complete. The supply of electrical energy will be given from the municipal generating station.

SUNDERLAND: *Sir James Laing & Sons' Works.*—In consequence of the suspension of payment by Sir J. Laing & Sons, shipbuilders, of Sunderland, the Corporation, which supplied electrical energy for lighting and power purposes in the works, have cut off the supply. Sir J. Laing & Sons owed the Corporation £2,300 for current, and the action of the Corporation was in consequence of the company refusing to treat them as preferential creditors. On Monday a meeting was held, at which it was decided to voluntarily wind up the business of Sir J. Laing & Sons.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ACTON.—Tenders are invited for the annual supply of meters, prepayment meters, carbons, house fuse-boxes, meter boards, and cables. Particulars from Mr. J. M. Blair, the Electrical Engineer, 130 Churchfield Road, Acton, and tenders to the Clerk by February 29th.

BARKING.—The Council invite tenders for the supply and delivery of electrical sundries, carbons, meters, &c. Full particulars from the Electrical Engineer's office, East Street, and tenders to the Town Clerk by February 25th.

BELFAST.—Tenders are invited by the Corporation for the supply of low-tension cable during the twelve months ending March 31st, 1909.

BOLTON.—The Electricity Committee have under contemplation improvements and extensions at the Electricity Works.

BRISTOL.—The Docks Committee invite tenders for the supply, delivery and erection, and maintenance for 12 months after they have been in use, of electric cables for the supply to Avonmouth Docks. The tenders are also to include the construction, delivery, erecting in place, fitting, completion, and testing and the maintenance for 12 months after they shall have been taken into use of the electric lighting installations, complete in all details, for the various buildings, railway yard, wharves, &c., at the Royal Edward Dock, now in course of construction at Avonmouth. Specifications, &c., from the Secretary of the Docks Committee (fee £5, returnable), and tenders to 19 Queen Square, Bristol, by February 27th.

BURSLEM.—A special meeting was to have been held yesterday for the purpose of considering the question of applying to the Local Government Board for sanction to a further loan in connection with the electricity works.

DARTFORD.—The Electricity Committee recommend that an Artesian well be sunk and that a surface condenser capable of dealing with 15,000 lb. of steam be installed. Application is to be made to the Local Government Board for sanction to borrow £1,900 for the surface condenser, artesian well, &c., and £1,100, which is the estimated capital expenditure during the next two years.

DUNDEE.—Tenders are invited for E.H.T. three-phase and direct-current switchboards and substation generating machinery. Full particulars from Mr. H. Richardson, the Chief Electrical Engineer (fee £3 3s., returnable), and tenders to the Clerk by March 2nd. (See an advertisement last week.)

GLASGOW.—The Tramways Department invite tenders for the supply and erection of two movable bridges over the Forth and Clyde Canal at Dalmuir and Kilbowie. Full particulars from the General Manager, 46 Bath Street, Glasgow, and tenders to the Town Clerk by April 15th.

HANDSWORTH.—Tenders are invited for (*a*): 315 kw. generating set, (*b*) feed-pump economiser and pipe work, (*c*) switchgear for 315 kw. generating set. Full particulars from Messrs. Kennedy & Jenkin, 17 Victoria Street, fee £3 3s., returnable, and tenders to the Town Clerk by March 4th.

HASLINGDEN.—The Corporation has received sanction from the Local Government Board for the erection of refuse destructor works at Priory Hill, at a cost of £8,500. These will be worked in conjunction with the Electricity Works.

HOLYWOOD (BELFAST).—Estimates have been placed before the Urban District Council to the effect that a generating station sufficient for public and private lighting can be installed in Holywood for £2,000, excluding the cost of buildings and mains. The matter has been adjourned for full consideration at the next fortnightly meeting.

HULL.—Tenders are invited for the supply and erection of three 500 kw. 2,250 volt continuous-current dynamos to be coupled direct to existing engines running at 250 rev. per minute. Particulars from the City Electric Engineer, and tenders to the Chairman of the Electric Lighting Committee, Town Hall, Hull, by February 27th.

ILFORD.—Tenders are invited for the supply and delivery of a 1,000-kw. steam generator, watertube boiler, &c. Particulars from the Council's Electrical Engineer, and tenders by February 28th.

LONDON: *London County Council.*—Tenders are invited for lighting the Hackney Downs secondary schools. Full particulars from the Clerk to the Council, and tenders by February 26th.

Fulham.—The Guardians invite tenders for electrical requisites, among other supplies, for the year ending March 31st, 1909. Samples and patterns can be inspected at the Guardians' offices, 129 Fulham Palace Road, Hammersmith, between 10 and 12 and 2 and 4 o'clock. Tenders to the Clerk not later than February 27th.

Hammersmith.—The Electrical Engineer has reported that it is now necessary to proceed with the installation of a battery to act as a stand-by for exciting the alternators. The installation was included in the extension scheme approved by the Council in 1904, and the estimated cost is £700.

Hampstead.—The estimated capital expenditure for the coming year ending March 31st, 1909, is £14,890, made up as follows:—Thermal storage drums, £1,060; water softener filter, £30; new boilers (after allowing for old boilers), £6,000; mains, £2,750; house services, £2,600; transformers, £750 and £400, and in case of the new Home Office Regulations being put in force an additional £300; meters and indicators, £1,000.

Islington.—Tenders are invited by February 25th for (*a*) one 1,500-kw. steam-turbine alternator, &c., (*b*) water-tube boiler, conveyor, &c.

Stoke Newington.—Mains are to be extended at an estimated cost of £332.

Woolwich.—The Council is to take up a loan of £2,394 for boiler plant required at the Electricity Works.

MANCHESTER.—The Electricity Committee invite tenders for the supply, delivery, and erection at the Stuart Street generating station of four water-tube boilers and accessories. Full particulars may be obtained from the Secretary of the Electricity Department at the Town Hall, fee £1 1s. returnable, and tenders to the Chairman of the Department by February 25th.

The Tramways Committee are inviting tenders for stores, including car wheel tyres, canopy trolley standards, overhead line material, lightning arresters, fuses, and fuse-boxes, incandescent lamps, car switches, bells, &c., telephone-

Digitized by Google

instruments, and power and lighting cables. Specifications, &c., from the General Manager, 55 Piccadilly, Manchester, and tenders to the Chairman of the Tramways Committee, at the same address, by February 24th.

STOKE-ON-TRENT.—A special report has been presented by the Electrical Engineer, in which he states that the generating plant will shortly require extensions. The amount borrowed for the purpose of the combined electricity and destructor undertaking up to date has been £40,000.

WIGAN.—Mr. J. Slevin, the Electrical Engineer, reports to his committee that the maximum load upon the electricity works during 1907 was 2,520 h.p., which was within 100 h.p. of the total capacity, thus leaving no spare engines in case of an abnormally heavy load or breakdown. He urges upon the committee, therefore, the absolute necessity for extensions of the plant immediately.

WOLVERHAMPTON.—The Corporation have agreed to the recommendation of the Electricity Committee providing for the laying of mains, &c., in connection with the proposed supply to the works of Messrs. T. Parker, Ltd., at an approximate expenditure of £2,500.

WREXHAM.—Tenders are invited for stores. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by March 6th.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Victorian Postmaster-General's department has accepted tenders from the following firms for telephone material :—British Insulated & Helsby Cables, Ltd., Melbourne; W. H. Hunter & Co., Melbourne; J. L. Drew, Melbourne; Millars' Karri & Jarrah Co. (1902), Ltd., South Melbourne; Cole Bentley, Melbourne; and F. Vanderkelen & Co., Melbourne.

BRISTOL.—The following tenders have been accepted by the Corporation upon the recommendation of the Electricity Committee :—Extra high-tension cable, Messrs. Siemen Bros. & Co., £21,787 17s. 4d.; 10-ton hand-travelling crane, Messrs. C. & A. Musker (1901) Ltd., £221; substation superstructure, Messrs. R. Wilkins & Sons, £2,939; coal, Ashton Vale Iron Co., £1,281 5s.

BRADFORD.—The following tenders are recommended for acceptance by the Tramways Committee :—Wire and cable, The India-Rubber, Gutta-Percha, and Telegraph Works Co., Ltd., £146; steam tubing, Messrs. Taylor & Parsons, £139 2s. 5d. Tenders of a large number of firms for miscellaneous stores to the aggregate value of £5,700 are also recommended for acceptance.

EDINBURGH.—The Edinburgh School Board have accepted the tender of Messrs. John Munro & Co., of Edinburgh, for the electric lighting installation at the Portobello High Grade School.

LONDON: *City of London.*—The City of London Board of Guardians has placed an order with Messrs. Pinching & Walton for the supply of 6 doz. electric lamps, 230 volts, at 8s. 9d. per doz. Repairs to telephones are to be carried out by W. Palmer for £3 8s.

Bermondsey.—The Borough Council has received the following tenders for a recording ammeter complete for 50 and 100 amperes :—Everett, Edgcumbe & Co. (accepted), £9 10s. 4d.; Elliott Brothers, £9 12s. 6d., less 2½ per cent.; Evershed & Vignolles, £14. All these prices were less 2½ per cent. Twelve enamelled iron plates for advertising the electricity undertaking are to be obtained from the Chromo Enamel Co., at a cost (three colours), of 6s. each.

City of London.—At the Court of Common Council last week an arrangement with the Postmaster-General for ten years' telephone system in connection with the City Electric Ambulance Service at £329 12s. 6d. per annum was approved.

Hammersmith.—The Electricity Committee has accepted the tender of Messrs. Thomas Parker & Co., Ltd., for the supply of a Rees roturbo patent self-regulating pump at £470. This pump will be capable of dealing with 250,000 gallons of water per hour.

LOWESTOFT.—The tender of the Lahmeyer Electrical Co. for service cable at an average price of £248 per mile has been accepted.

QUEENSLAND.—The Postmaster-General's department has accepted tenders from the following firms for telephone, telegraph instruments, parts and material :—Oswald Haes, Sydney; G. R. Hodson, Brisbane; Lawrence & Hanson, Sydney; India-Rubber, Gutta-Percha, and Telegraph Works, Ltd., Sydney; Trackson Bros., Brisbane; Brisbane Electric Co., Brisbane; Jas. Paton & Co., Sydney; International Electric Co., London; British Insulated & Helsby Cables, Ltd., Melbourne; C. E. Bernays, Brisbane.

COMPANIES' MEETINGS AND REPORTS

BAKER STREET AND WATERLOO RAILWAY.—At the half-yearly general meeting on Monday, Sir G. Gibb, who presided, said he thought he might say the company was making rapid progress. The gross receipts showed an increase of 55 per cent. over those of the corresponding period of the previous year, and after providing for interest and rents and crediting to net revenue account the amount receivable from the Underground Electric Railways Co. of London there remained a balance of £17,670. This was the first half-year in which it had been possible to compare their position with corresponding periods. The passengers carried had increased by 3,868,981, while the traffic receipts had increased by £22,272. This rate of progress was being maintained during the current half-year, and during the first five weeks the receipts per week had shown an increase of 15½ per cent. The report and accounts were adopted.

BRISTOL TRAMWAYS AND CARRIAGE.—The report for the year 1907 shows gross receipts of £263,689, and working and general expenses £178,342, leaving a net revenue of £85,347. A final dividend at the rate of 9½ per cent. for the year is recommended, and £8,708 added to reserve fund. The company's investments on December 31st, at market value, amounted to £166,536, but since the close of the year additional investments have been made, bringing the total up to £179,826. With the addition of the sum now proposed, the reserve fund stands at £188,534. Mention is made in the report of the fact that the issue of 250,000 4½ per cent. mortgage debenture stock was oversubscribed.

Sir G. White, presiding at the annual meeting on Monday, said that their tramway receipts, which had decreased by £392 compared with 1906, had doubtless been affected by weather conditions. The total receipts of the company showed the net decrease of £3,080, the difference between this sum and £392 being upon the carriage department of their business. By rearranging the service they had been able to make a considerable reduction in the car mileage and bring up their receipts per car mile from 8·68d. to 9·27d. The number of passengers carried was 46,585,050, against 46,902,257. A special meeting was held after the ordinary general meeting, when a resolution to proceed with the company's Bill now before Parliament was carried.

BRUSH ELECTRICAL ENGINEERING.—The adjourned meeting of the 4½ per cent. perpetual debenture holders was held on Friday for the purpose of considering a resolution for consolidating the company's debenture stock. Lord Vaux of Harrowden stated that since the previous meeting (ELECTRICAL ENGINEREERING, February 13th, p. 231), the Board had communicated with several of the holders of both classes of debenture stock, and it was hoped that the scheme would now be looked upon in a more favourable light. The original proposal of the Board was to raise new 4½ per cent. stock, and in addition that a sum equivalent to ½ per cent. per annum should be provided as a sinking fund. After carefully considering the objections made to this amount as not being large enough, the Board have agreed to set aside 1 per cent. As the stock was redeemed the interest would be added to the fund, but instead of the interest on the sinking fund being £8,750, it would be £9,625. A good deal of discussion followed the speech of the chairman, and when the resolution was put to the meeting it was declared to be lost. A poll was demanded, but the chairman refused to take it at once on the ground that several of the shareholders had not had time to thoroughly consider the proposed change in the plans. It was arranged that the poll should be taken on the 27th inst., at 12 o'clock, and a meeting of the second debenture holders, which was to be held on Friday, following that of the first debenture holders, has been adjourned until after the result of the poll is announced.

BUDE ELECTRIC SUPPLY.—At the statutory meeting held on the 14th inst., the chairman stated that the number of shares allotted was 3,200, on account of which calls to the amount of £1,335 have been received. The preliminary expenses amounted to £140.

CENTRAL ELECTRIC SUPPLY, LONDON ELECTRIC SUPPLY, NOTTING HILL ELECTRIC LIGHTING, AND WESTMINSTER ELECTRIC SUPPLY.—The reports of these companies are given on page 275 of this issue.

CHATHAM AND DISTRICT LIGHT RAILWAYS.—The report for the half-year ended December 31st, 1907, shows receipts amounting to £20,207, and expenses to £12,799, leaving a balance of £7,408. Interest on debentures absorbs £1,284, and the amount written off, mainly in connection with abandoned lines, is £5,555. There thus remains the sum of £619,

Digitized by Google

to which is added balance brought forward from June 30th, 1907, viz., £4,492, making £5,111 available for distribution. Owing to the bad weather experienced throughout the year and slackness of trade in the Chatham district, the traffic revenue has been very disappointing, there being an increase of only £1,580 over the previous year's receipts, although the Rainham extension was open for the full year, as compared with three months of the year 1906. During the half-year £1,900 debentures and £1,900 preference shares have been issued, and the proceeds utilised in reducing the company's indebtedness. Capital expenditure during the half-year amounts to £2,059, mainly expended on additional plant in power station. In September last the Board of Trade issued, on the application of the Gillingham Corporation, an order declaring that the powers of the company in respect to the lines in Pier Road (1,246 yards in length) should cease and determine. The cost of the line and reinstating the roadway, less materials taken up, amounts to £4,528 9s. 5d., and the directors in the circumstances have considered it advisable to write the full amount off, and the balance cost of the line abandoned in Westcourt Street, viz., £666 5s., and recommend that the balance profit after transferring £3,000 to reserve for depreciation be utilised in paying a dividend at the rate of 3 per cent. per annum for the half-year on the preference share capital, carrying the balance remaining of £347 to the accounts for the current year. The Rochester Corporation extension lines to Strood Hill and Frindsbury referred to in the previous report are expected to be completed before Easter and leased to the company. The meeting will be held on March 5th.

CLONTARF AND HILL OF HOWTH TRAMWAYS.—The directors' report for the year 1907, states that the new working agreement with the Dublin United Tramways Company came into operation on January 1st, 1907, and the company duly received the sum of £2,000 under the terms of that agreement. After paying debenture interest, wayleaves, and management expenses, there remains a surplus of £585 14s. 4d., from which has to be deducted £23 5s. 8d., being the balance at debit from last account, leaving a net balance of £562 8s. 8d. Out of this it is proposed to pay a dividend of 1 per cent. on the ordinary shares, absorbing £499 16s., and to carry forward £62 12s. 8d. to next year's account. Under the terms of the agreement with the Dublin United Tramways Co. the company is entitled to £2,500 in respect of the current year, and £3,000 in respect of next and subsequent years. The first-named sum will enable the payment of a dividend to be made at the rate of 2 per cent. per annum, and the latter sum at the rate of 3 per cent. per annum. As the payments are received half-yearly from the Dublin United Tramways Co., the dividends will in future be paid half-yearly. The report was adopted at the meeting last week.

DISTRICT RAILWAY.—The meeting was held on Wednes- last week at the Westminster Palace Hotel, Sir G. Gibb, chairman, presiding. He stated that the deficit of £45,551 shown in the accounts (ELECTRICAL ENGINEERING, February 13th) had been paid out of capital, but they had now practically come to the end of their available capital assets. They had carried 28,838,732 passengers, an increase of 19,605, and had earned £4,595 more in passenger receipts. They estimated that during the last half-year the loss of revenue from traffic diverted by the Great Northern, Piccadilly and Brompton Railway amounted to £22,830, after deducting the District share of through traffic with that railway. The working expenses were £12,133 more than in the June half of last year, but were practically identical with those for the December half of 1906, but this was due to the fact that they had run more trains. In order to dispel any idea that the working cost on the District Railway was extravagant or excessive, he gave some figures of the working expenses upon other London electric railways. The cost of train working, including interest on capital for generating plant, was as follows upon various London tube railways :— City and South London, 1·22d. per car mile; Great Northern, Piccadilly, and Brompton Railway, 1·59d.; Metropolitan District Railway, 1·75d.; Charing Cross, Euston and Hampstead Railway, 1·76d.; Central London Railway, 1·83d.; Baker Street and Waterloo Railway, 1·85d.; Great Northern and City, 1·95d. For the same railways he gave the following figures of traffic expenses as percentage of traffic receipts :—City and South London, 11 per cent.; Metropolitan District, 12 per cent.; Great Northern, Piccadilly and Brompton Railway, 13 per cent.; Central London, 14 per cent.; Baker Street and Waterloo, 14 per cent.; Great Northern and City, 15 per cent.; Charing Cross, Euston and Hampstead, 18 per cent. Dealing at length with the financial position of the company, Sir G. Gibb gave in detail the proposed arrangements for raising fresh capital, set forth in the circular to the shareholders in November, which was given in full in our issue of November 28th. The report and accounts given in our last issue were then adopted with one dissentient, who was a debenture holder.

A special general meeting was subsequently held for approving the Bill for making further provision respecting the capital of the company, when a resolution to this effect was passed.

DUBLIN & LUCAN ELECTRIC RAILWAY.—The gross receipts for the half-year to December 31st are £3,576 10s. 1d., being £256 5s. 11d., in excess of those of the corresponding period of last year. After providing for debenture interest there is an available balance of £987 5s. 6d., out of which the directors recommend the payment of the usual half-yearly dividend on the 5 per cent. preference shares, and that the balance of £512 5s. 6d. be carried forward to next half-year, as against £644 2s. 7d. carried forward for the corresponding period of the previous year. The meeting will be held to-day.

At the meeting on Thursday, the chairman, Mr. W. Mooney, said that whereas the receipts showed an increase of £256 over the corresponding period of the previous year, the expenditure had increased by £405, mainly due to extra cost of electric power and maintenance of permanent way and works; the increased price of coal had also contributed to this result. They had decided to continue the expenditure upon the permanent way, until the whole line had been put into a thoroughly efficient state. In order to make the line as attractive as possible, the directors, had, among other improvements, introduced electric heating in the cars. The report and accounts were adopted.

EDMUNDSON'S ELECTRICITY CORPORATION.—An extraordinary general meeting was held at Salisbury House, London Wall, on Tuesday, under the chairmanship of Mr. F. E. Gripper, to consider a report of the committee appointed in July last to investigate the affairs of the company. This report stated that the non-success of the company was due to a combination of injudicious capital expenditure, unwise management, and imprudent finance. The committee recommended that the resignation of the old members of the Board be accepted, and that Mr. Tuckett be appointed chairman of the company, and that Mr. Campbell Swinton be elected to the Board; that Mr. Stanley Beeton be invited to the Board; that Mr. J. S. Highfield, chief engineer to the Metropolitan Electric Supply Co., be invited to assist in the reorganisation of the company's business; and that Mr. F. E. Gripper should act as manager to the London office, and as the representative of the Corporation upon the Boards of the local companies. The report further stated that immediate steps must be taken to provide additional capital. After careful consideration the capital requirements for the next four years were estimated to amount to £250,000, and the committee were reluctantly compelled to suggest as the only practicable course, the issue of prior lien debenture stock. During the discussion upon this report it was stated that Mr. Gripper would subordinate his personal views and likings in his position as manager entirely to the views of the directors. There was a good deal of opposition to the issue of prior lien debentures, and a suggestion was made that the committee should take back for consideration its recommendation with regard to finance. An amendment to omit from the report the financial proposals and the recommendation with regard to the appointment of Messrs. Beeton, Highfield, and Gripper was lost, and the original resolution was carried. A demand for a poll was subsequently withdrawn.

GREAT NORTHERN, PICCADILLY & BROMPTON RAILWAY.—The half-yearly meeting was held on Tuesday, Sir George Gibb presiding. The Chairman traversed all the statements made in his report, given on page 227 of our issue last week, and stated that the receipts for the first seven weeks of 1908, compared with those of the first seven weeks of 1907, showed an increase of 43 per cent. The report and accounts were adopted, and at the subsequent special meeting a resolution approving the company's Bill in Parliament was passed.

HASTINGS & DISTRICT ELECTRIC TRAMWAYS.—The report for the year ending December 31st, 1907, shows receipts aggregating £24,099, or, after deducting administration expenses, £22,206 1s. 7d.; adding to this the sum of £300 12s. 6d. for interest earned on moneys in hand, and £733 6s. 10d. brought forward from last account, and deducting £9,472 10s. debenture stock interest, there remains a balance of £13,767 10s. From this has been paid during the year by way of interim dividend on the preference shares the sum of £4,000, being at the rate of 4 per cent. per annum, and the directors now propose to pay a further sum of £8,000, being at the rate of 8 per cent. per annum, making the full 6 per cent. for the year 1907, and to carry forward the balance of £1,767 10s. The Front line was opened for traffic on January 12th, 1907, and therefore the completed system has been in operation for practically the whole year. Having regard to the unfavourable weather which was generally experienced throughout the year, the directors consider the result to be satisfactory. The meeting will be held on Monday. The following statistics are given in the report :— Miles of line, 19½; number of cars, 65; car mileage, 1,436,014; passengers carried, 9,530,345; traffic receipts per car mile, 9·05d.; total expenses per car mile, 5·47d.

The meeting was held on Monday, Mr. E. C. Morgan, chairman, presiding. The Chairman pointed out that the expenses were about 60 per cent. of the receipts, and although it was hoped to reduce this rather large percentage, they did not expect to emulate the figure of other lines where the conditions were much less onerous than those of Hastings. He referred to the fact that in connection with the line along the sea front, which gave a direct communication between Hastings and Bexhill, they had been compelled to adopt some other system than the overhead. They had therefore to fall back on one of the surface contact systems (the conduit system being almost impossible), although very little was known as to their merits, and

Digitized by Google

practically nothing of the particular system which had been put into operation, namely, the Dolter system. They were, therefore, the pioneers of this system in England, and for a considerable period they experienced many difficulties which did not tend to improve their traffic. By patience and perseverance however, they had surmounted many of the difficulties, and the line was now working in such a manner as to lead the directors to hope for fairly good results. The report and accounts were adopted.

IMPERIAL TRAMWAYS.—The gross revenue receipts from the Middlesbrough, Stockton, and Thornaby Tramways during the year ended December 31st, 1907, amounted to £54,747, a decrease of £587 over the previous year. £2,500 is placed to reserve, leaving a net profit of £16.884. The receipts from the London United Tramways were £21,111, this being the same as for the previous year. The net revenue of the Imperial Company for the year shows a gross profit of £41,573, which is reduced to £26,125 after payment of interest on debenture stock for the whole year, and interim dividend on the preference and ordinary shares up to June 30th, 1907. Dividends are proposed of 6 per cent. per annum on the preference capital, and final dividends of 10 per cent. per annum, making 9 per cent. for the year on the ordinary shares. The sum of £248 is carried forward.

The report and accounts were adopted at the meeting on Monday, the Chairman stating that the past year's experience had been without any special feature, and called for no special comment.

LIVERPOOL OVERHEAD.—At the half-yearly meeting last week, the report and accounts given in our issue for February 6th were adopted. Sir W. Forwood, the chairman, who presided, said that there were indications that they had now to some extent discounted the pressure of tramway and railway competition, and were reaping some benefit from the annual growth of dock side traffic. The receipts per passenger, he pointed out, were only 1·77d., against 1·93d., which was the figure when the company was paying a 5 per cent. dividend, and this low average was due to the heavy workmens' traffic.

ST. JAMES'S & PALL MALL ELECTRIC LIGHT.—At the ordinary general meeting, held at the office of the company in Carnaby Street, on Tuesday, the report and accounts given on page 273 of this issue were adopted. Having gone through the figures of the report, the Chairman stated that with regard to the future he was not going to make any promises, but he would state that the first result of the effect of metallic filament lamps upon their business was a sensible loss of revenue; but it need not be feared that these new lamps were going to be an unmitigated disadvantage, as undoubtedly they would tend to the greater use of electrical energy by a class of people who now regarded it as a luxury.

SOUTH METROPOLITAN ELECTRIC LIGHT AND POWER.—The report for the year ended December 31st, 1907, shows a credit balance of £27,068, which, with £7,104, the balance brought forward from the last account, makes a total of £54,172. After deducting £9,792 for interest on debenture stock paid and accrued, and for other interest, and £4,128 for interim dividend paid on the 7 per cent. cumulative preference shares, there remains a balance of £20,250, which the directors recommend be dealt with as follows:—A final dividend upon the 7 per cent. cumulative preference shares, £4,555; depreciation account, £5,500; dividend upon the ordinary shares at the rate of 2½ per cent. per annum, £3,011; carried forward, £7,182. During the year a further £19,262 debenture stock, 25,000 preference shares, and 3,000 ordinary shares of £1 each were issued. The premiums arising from the issue amount to £3,487. The directors have applied £1,987 of the amount in the reduction of preliminary expenses account, and have carried the balance, £1,500, to reserve account. Eight of the London electric supply companies, including this company, are jointly promoting a Bill in the present session of Parliament for the establishment of a joint committee, and to make agreements for mutual assistance, and for the supply of energy in bulk to and the taking of energy from one another. The Bill will be submitted for consideration, and a resolution proposed to approve the same after the general meeting on the 26th inst.

SOUTH WALES ELECTRIC POWER DISTRIBUTION.—A special general meeting was held at Cardiff last week, at which the company's Bill, of which full particulars were given in our issue for December 26th, was agreed to. A meeting of the debenture shareholders was afterwards held under the chairmanship of Mr. T. O. Callender, and the resolution to promote the Bill was also passed. It was stated that arrangements have been entered into with creditors to the extent of £79,000, for the annulment of the amount owing them by the creation of preference stock at the rate of 150 per cent. face value of the stock for every £100 of indebtedness. Creditors to the amount of £4,000 were unable to give their assent to this proposal, however, but the Bill contained a clause compelling them to accept preference shares on the terms above mentioned. Power is taken in the Bill to raise £500,000 by means of prior lien debenture stock, and to postpone the payment of interest on the £200,000 existing debentures for a period of three years, namely, until January 1st, 1910.

TYNESIDE TRAMWAYS & TRAMROADS.—The report for the half-year ending December 31st, 1907, shows a surplus of receipts over expenses of £3,785, which, with the balance brought forward from last half-year of £600, makes a total of £4,385 available, and after deducting interest on mortgages, loans, &c., there remains an available balance of £2,968 8s. 1d. The directors propose a dividend on the preference shares of 5 per cent. per annum (less income tax); a dividend on the ordinary shares of 2½ per cent. per annum (less income tax), as compared with 2 per cent. for the corresponding half-year of 1906; placing to the credit of reserves for renewals, depreciation, and other contingencies, £600, increasing this fund to £4,600. The amount carried forward is £422. The whole of the track, overhead line, and rolling stock has been kept in thorough repair during the past year out of revenue. The recent issue of preference shares has been satisfactory, inasmuch as 2,033 shares have been applied for out of a total of 3,000 offered for subscription. The following statistics are attached to the report:—Car miles (Tyneside Tramway Co.'s cars), 679,692; passengers carried (Tyneside Tramway Co.'s lines), 4,703,459; total traffic receipts, £24,068; gross profit, £8,261.

Dr. J. T. Merz, who presided at the meeting last week, said the traffic receipts had increased by 4¼ per cent., and the car miles run by ¾ per cent. In other words, though running a trifling number of miles more they had carried very many more passengers, with the result that the receipts per car mile had increased from 8·18d. to 8·49d. The cost had increased from 5·64d. per car mile in 1906, to 5·82d. in 1907. The report and accounts were adopted, and upon the motion of the chairman, the number of the directors of the company has been reduced to five.

YORKSHIRE (WEST RIDING) ELECTRIC TRAMWAYS.—The report for the year ended December 31st, 1907, states that the operations of the past twelve months, after providing for all expenses, including repairs and renewals, resulted in a net income of £27,377. Adding the balance brought forward from last year, £4,443, the available profit is £31,821. This profit has been dealt with as follows:—Debenture interest (less income-tax) on 4½ per cent. stock, £11,756 5s.; debenture interest (less income-tax) on 6 per cent. bonds, £744 11s. 3d.; sundry reserves as per appropriation account, £9,856 14s. 7d.; carried forward, £9,463 8s. 11d. The number of passengers carried during the past year amounted to 8,627,247, and the miles run to 1,758,669, as against 6,169,148 and 1,414,767 respectively for the previous year. The increase of passengers is chiefly due to the completion of the Normanton and Pontefract section, but a satisfactory expansion of traffic is also shown on the old routes. The meeting takes place to-morrow at 14 Victoria Street, Westminster.

APPOINTMENTS AND PERSONAL NOTES

Sir John Gavey, C.B., late Engineer-in-Chief to the Post Office, has been appointed consulting engineer to that department.

The Woolwich Borough Council has passed increases of £10 per year each to the salaries of officials in the Electricity Department as follows:—F. H. Edwards, station engineer, and S. H. Penning (present salaries, £180); H. H. Clare, charge engineer (£140); T. W. Bunce, charge engineer (£120); C. A. Trayte, draughtsman (£100).

The salary of the Electrical Engineer to the Ealing Corporation, Mr. C. S. Davidson, has been increased £25 per annum; that of Mr. Law, the assistant in the Electricity Department, £10 per annum; and that of Mr. Kieffer, the shift engineer, £5 per annum.

The salary of Mr. A. L. C. Fell, chief officer of the London County Council tramways, has been increased from £1,500 to £1,750 per annum. In making this recommendation the General Purposes Committee point out that since Mr. Fell was appointed in November, 1903, additional tramway undertakings have been taken over, and a large proportion of the lines reconstructed for electrical traction by the Council; as an instance of the rapid growth of the service it is mentioned that the number of passengers carried has increased from 126,388,845 in 1903 to 351,407,794 in 1907, whilst during the same period the receipts have increased from £489,369 to £1,536,196. At the time the salary of £1,500 was fixed, it was not contemplated that the northern tramways system would be taken over before 1910.

Mr. E. L. Pope, resident electrical superintendent for the L.C.C. tramways, has had his salary increased from £400 to £425 per annum, and Mr. G. Dickens, superintendent of stores, from £250 to £300 per annum.

A resolution to increase the salary of Mr. H. W. Angus, the Electrical Engineer to the Eccles Town Council, by £50, was discussed at some length at the last meeting of the Council, and was defeated, the recommendation being referred back to the committee.

The Gravesend Corporation has agreed to a recommendation by the Electric Lighting Committee to increase the salary of Mr. C. F. McInnes from £300 to £400 by annual instalments of £50, £50, and £20, on condition that Mr. McInnes remains with the Corporation for a further period of three years.

Mr. Owen L. Rhys has been appointed to the position of medical officer in charge of the electrical department at the Cardiff Infirmary.

PARLIAMENTARY INTELLIGENCE

GREAT EASTERN RAILWAY (GENERAL POWERS) BILL.—At the meeting of the Ipswich Town Council last week, when a resolution was under discussion with regard to opposing Section 19 of this Bill, which gave the G.E.R. Co. more or less general powers of electric supply, it was stated that a communication had that morning been received from the company to the effect that the clause in question had been deleted from the Bill.

PETITIONS AGAINST PRIVATE BILLS.—The period for depositing petitions against Bills originating in the House of Commons expired last week. Against the Dublin and Central Ireland Electric Power Bill petitions have been lodged by the Dublin Corporation, Dublin County Council, Rathmines, Pembroke, and Blackrock Councils, and the Dublin United Tramways (1896). The London United Tramways Bill is opposed by the National Telephone Co., Richmond Corporation, Surrey County Council, and the promoters of the West London, Barnes, and Richmond Tramway Bill. There are a number of municipal general powers Bills containing tramway clauses which will be opposed, but the above two Bills seem to be the only ones calling for special comment. The most controversial Bills, viz., the London Electric Power Bills, commence in the House of Lords, and the period for depositing petitions has not yet expired. Already, however, petitions have been lodged against the London and District Electricity Supply and the London Electric Supply (Joint Committee) Bills by the Camberwell Borough Council, City of London Electric Lighting Co., and the Gravesend, Ealing, Hendon, Hornsey, Dartford, Leyton, West Ham, Westminster, and Friern Barnet Corporations. The Bristol Corporation is opposing the Bristol Tramways Bill, the Hornsey Corporation the Highgate Hill Tramways Bill, and petitions upon minor points have been lodged against the Metropolitan Electric Tramways and other Bills.

PROGRESS OF ELECTRICAL BILLS.—The Nottinghamshire and Derbyshire Tramways Bill was read a second time in the House of Commons on Monday. The Metropolitan Electric Tramways Bill was read a first time in the House of Lords on Thursday. The Macclesfield and District Tramways (Abandonment) Bill, and the Central Ireland Electric Power Bill, were read a second time in the House of Commons on Tuesday.

RADIOTELEGRAPHIC CONVENTION.—In the House of Commons on Thursday, in reply to Sir John Dickson Poynder, the Postmaster-General stated that all the self-governing Colonies had notified their intention of adhering to the Radiotelegraphic Convention, with the exception of Newfoundland, which had not yet communicated its decision, and the Orange River Colony, which, as an inland colony, sees no necessity for adhering to the Convention.

TELEGRAPH (CONSTRUCTION) BILL.—A Bill has been introduced into the House of Commons by the Postmaster-General to amend the Telegraph Acts, 1863 to 1907, with respect to the construction and maintenance of telegraphic lines for telephonic and other telegraphic purposes. The Bill provides for the use of land near roads for telegraphic purposes, the flying of wires overland adjoining a road so used, and the lopping of trees which obstruct any telegraphic line.

In the memorandum which the Postmaster-General has published, explaining the provisions of this Bill, he states that the Department is placed in great difficulties where the most convenient road for telegraph lines is alongside a road which has no grass margin, and the owner of the land adjoining refuses permission for poles to be erected. Under the Bill, in cases where there is such an objecting landowner, the Postmaster-General may appeal to a County Court judge and the Railway Commissioners. The same procedure is allowed where the Postmaster-General desires to place his posts on private land within 20 ft. of the road not forming part of the road. The Bill further extends the provision of the Telegraph Act of 1892, which enables the Postmaster-General to obtain a Provisional Order from the Railway Commissioners giving him access to a place where he is altogether barred by the unreasonable attitude of the landowner.

NEW COMPANIES

ADDINELL & CO.—This company was registered on February 13th, with a capital of £1,500 in £1 shares, to take over the business of an electrical engineer and contractor carried on by J. G. Addinell, at Saracen Buildings, Snow Hill, E.C., as the "A. C. Electrical Co." and at Eagle House, Great Darkgate Street, Aberystwyth, Cardiganshire, as "Addinell and Humphreys." and to adopt an agreement with the said vendor. The subscribers are:—R. S. Phillips, R. E. Burnage, J. J. McIntyre, J. G. Addinell, G. H. Palmer, A. E. Timberlake, P. H. McIntyre. No initial public issue. The number of directors is not to be less than two nor more than five; the first are J. G. Addinell and J. J. McIntyre. Qualification £10. Remuneration as fixed by the board. Registered office, Saracen Buildings, Snow Hill, E.C.

ARBROATH ELECTRIC LIGHT & POWER CO.—This company was registered in Edinburgh on January 30th with a capital of £30,000 in £1 shares to carry on the business of an electric light, heat, and power supply company, to undertake the lighting by electricity, gas, or other illuminant of towns, streets, buildings, and other public or private places, particularly near Arbroath, to construct, maintain and work by electricity or other power tramways, or other undertakings, &c. The subscribers are:—G. Balfour, A. H. Beatty, J. B. White, A. Shepherd, R. F. Shepherd, W. Shearer, J. A. Ferguson. The first directors are to be afterwards appointed. Qualification, 100 shares. Remuneration as fixed by the company. Registered office, Brothock Bank House, Arbroath.

COLONIAL RAIL & TRAMWAY SYNDICATE.—This company was registered on February 14th, with a capital of £2,100 in 2,000 "A" shares of £1 each, and 2,000 "B" shares of 1s. each, to construct, work, develop, or control railways, tramways, and other public works and conveniences of all kinds in any British Colony, Dependency, or elsewhere, and to carry on the business of financiers, capitalists, company promoters, concessionaires, &c. The subscribers are:—W. H. Hodges, F. W. Gibson, E. H. Burton, A. H. Lansdowne, D. Lewes, G. Brodie, P. J. Miller. No initial public issue. The subscribers are to appoint the first managers. Registered office, 16 St. Helen's Place, E.C.

ELECTRELLE.—This company was registered on February 14th, with a capital of £10,000 in £1 shares (55 founders'), to carry on the business of manufacturers of and dealers in "Electrelles" and other mechanical contrivances or devices for playing, producing, or reproducing sound from pianofortes, organs, harmoniums, and other musical instruments, &c. The subscribers are:—H. Whitcombe, J. C. Burrows, F. Cox, J. Oates, J. Hall, F. W. Browne, W. F. Hughes. No initial public issue. The number of directors is not to be less than three, nor more than seven; the first are J. E. Prestwich, R. H. Prestwich, W. H. Fish, and A. W. Stevenson. Remuneration as fixed by the company. The holders of the founders' shares shall be entitled: (*a*) to 55 per cent. of the distributed profits, and (*b*) to 55 per cent. of the surplus assets in the event of winding up. They shall also, in addition to one vote for every share held by them respectively, be collectively entitled to as many votes as the holders of all the other shares for the time being issued shall be entitled in respect of such other shares. Registered office, 13 Spring Gardens, Manchester.

LAIDLER, RITCHIE & CO.—This company was registered on January 30th with a capital of £6,000 in £1 shares (3,000 preference) to acquire the business of electrical engineers carried on by Laidler & Co. (formerly known as "Laidler, Laidler & Co."), of Pink Bank Lane, Longsight, Manchester, and to carry on the same and the business of manufacturing electricians, makers and suppliers of apparatus used in connection with the distribution, supply, accumulation, and employment of electricity, &c. The subscribers are:—F. Raimes, W. Raimes, F. T. Nattrass, W. C. Laidler, T. E. Ritchie, J. S. Proctor, and E. E. Kellett. No initial public issue. The number of directors is not to be less than two, nor more than five; the first are F. Raimes, W. C. Laidler, and T. E. Ritchie. The two last named are permanent managing directors; special qualification, 300 ordinary shares. Qualification of ordinary directors, £200 shares or stock. Remuneration of first managing directors, £100 each per annum (£150 per annum when only one): of ordinary directors as fixed by the company. Registered office, Nutsford Vale Works, Pink Bank Lane, Longsight, Manchester.

LEE'S ENGINEERING CO.—This company was registered on February 3rd with a capital of £1,000 in £1 shares to acquire the business carried on by J. Lee at Station Road, Oswestry, Salop, and to carry on the business of mechanical, electrical, and general engineers, founders, manufacturers of, and dealers in electric light fittings, art metal workers, fitters of bells, telephones, and signalling appliances and apparatus, dealers in boiler and non-conducting composition for coating purposes, &c. No initial public issue. The number of directors is not to be less than three, nor more than seven; the first are E. B. Smith, G. Perks, W. Foulkes, and W. W. Coulson. Registered office, Station Road, Oswestry, Salop.

LEWIS & DAVID.—This company has been registered with a capital of £6,000 in £1 shares to carry on the business of electrical, mechanical, civil, and mining engineers, &c. No initial public issue. Registered offices, Port Talbot Foundry, Isaac's Place, Aberavon, Glam.

SCHREIBER ELECTRIC BATTERY CO.—This company was registered on February 5th with a capital of £7,000 in 5,000 preference shares of £1 each, and 40,000 deferred shares of 1s. each, to acquire certain inventions or processes relating to the manufacture of electric batteries, to adopt an agreement with P. Schreiber, and to carry on the business of manufacturers of and dealers in all kinds of electric batteries, accumulators, and self-propelled vehicles, electricians, electrical engineers, &c. The subscribers are:—H. Leighton, W. F. Hutchison, H. Foster, P. Schreiber, J. Bruce, S. G. Barnes, A. F. Robinson. No initial public issue. The number of directors is not to be less than three, nor more than six. P. Schreiber is managing director. Table "A" mainly applies. Registered office, 25 Brewer Street, Regent Street, W.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £58 10s. to £59 per ton (last week £61 10s. to £62 10s. per ton).

"TANTALUM" LAMPS.—Messrs. Siemens Bros.' Dynamo Works, Ltd., notify us that from the 10th inst., the 16 c.p. and standard "Tantalum" lamps have been reduced to 2s. 6d. The price of the "Sun" bulb lamps remains at 5s. 6d.

MESSRS. HARRIS, LEE & CO.—A meeting of the creditors of Messrs. Harris, Lee & Co., of Johannesburg and London, was called yesterday, and we understand that a statement of affairs has been prepared which shows liabilities to sundry creditors £9,517 6s. 5d., debentures and interest £4,274 7s. 10d., and partly secured creditors making the liabilities total £15,570 9s. 10d. The assets total £17,438 9s. 8d.

It appears that the company was registered at Johannesburg on February 15th, 1905, with a capital of £11,421, to carry on the business of electrical and contracting engineers. The business was conducted at Johannesburg only at the date of the incorporation, but a concession was obtained from the municipality of Heilbron, in the Orange River Colony, and the work is in course of erection. This concession, which was afterwards sold, resulted in a total loss to the company of £1,600. A similar concession was obtained in October, 1904, in the town of Bethlehem in the same colony, and, though this is being worked at a small loss, it is still being carried on by the provisional liquidators with a view to a sale. A business carried on in Pretoria, which the company took over in 1906, was carried on at a loss, as was also a business in Doornfontein, and both these businesses have been closed. A contract was obtained from the municipality of Krugersdorp in May of last year for public lighting, and a branch office was opened there. Several contracts were obtained, and these are now practically completed. A synopsis of the trading from the date of the incorporation of the company shows that losses have been made at Johannesburg and other branches amounting to £4,258, while £768 has been written off amount owing by directors, and £8,500 off goodwill. The provisional liquidators are of the opinion that the liquidation has been brought about by insufficient working capital, over-trading, and the adoption of too large a policy of expansion, with a consequent lock-up of capital; having the business too much scattered, involving difficulty of supervision and consequent loss, high expenses of administration and heavy rents; a tendency to cut prices in order to secure business, and the consequent failure to make adequate gross profits, and absence among the management of one controlling hand to watch the finance and stop extravagance. The following are the chief creditors :—Atlas Carbon & Battery Co., £33; A.E.G. English Manufacturing Co., Ltd., £56; M. Bateman & Co., £47; Berry, Skinner & Co., £79; British Prometheus, Ltd., £20; C. Conradty, £15; Cole Marchant & Morley, Ltd., £206; J. Defries & Sons, Ltd., £60; Dorman & Smith, £13; Drake & Gorham, Ltd., £16; Everett, Edgecumbe & Co., Ltd., £14; Electric & Ordnance Accessories Co., Ltd., £139; Ecco Battery & Electric Co., Ltd., £17; Estler Bros., £13; Edison & Swan U.E.L. Co., Ltd., £13; Gwynnes, Ltd., £63; Gilbert Arc Lamp Co., Ltd., £274; Hooper's I.R. Works, Ltd., £52; Hawkes, Ltd., £15; Cecil Hodges & Co., £25; Johnson & Phillips, Ltd., £12; Marples, Leach & Co., £45; Morgan Crucible Co., Ltd., £38; Plutte, Scheele & Co., £11; Rumney & Rumney, £167; Sloan Electric Co., Ltd., £10; Spagnoletti, Ltd., £20; Saxon Electrical Co., Ltd., £58; Sterling Telephone & Electric Co., £137; Simplex Conduits, Ltd., £1,236; Dr. Henrick Traun & Sons, £12; J. H. Tucker & Co., £76; Union Electric Co., Ltd., £35; Walsall Electric Co., Ltd., £10; Ward & Goldstone, £81; Zurich Incandescence Lamp Co., Ltd., £1,113. Among the South African creditors are :—A.E.G. Electrical Co., Ltd., £75; African Merchants, Ltd., £25; British General Electric Co., Ltd., £89; R. C. Brown, £25; H. Daniels, £59; C. J. Duncan, £100; W. M. Edwards, £10; W. H. Ferrar, £47; Giddey & Sparkes Clarkson, £60; A. J. Geard & Co., £55; Henley's Telegraph Works Co., Ltd., £101; Harvey & Co., Ltd., £16; D. M. Kisch & Co., £12; Natal Government Railways, £116; Parker, Wood & Co., Ltd., £11; Reunert & Lons, £11; Robson & Holton, £18; Stewarts and Lloyds, Ltd., £104; S.A. Investment Co., Ltd., £30; W. D. Smith & Sons, £10; W. P. Sole & Co., £18; Seehoff & Victor, £14; E. W. Tarry & Co., Ltd., £18; Telegraph Manufacturing Co., Ltd., £1,590; Transvaal Rubber Co., £10; Vacuum Oil Co., £115; Western Electric Co., £117.

W. F. JONES & CO.—A meeting of the creditors of C. H. Rosoman & Sidney Dicks, trading as W. F. Jones & Co., Dacre House, Victoria Street, London, S.W., was held on the 11th inst., when a statement of affairs was submitted, showing liabilities amounting to £752 2s. 9d., all of which was due to unsecured trade creditors. After allowing £18 6s. 3d. for preferential claims, the assets were expected to produce £581 8s. 9d., a deficiency thus being disclosed of £170 14s. In order to protect the estate a deed of assignment has been executed. The trustee under the deed (Mr. Abernethy) had received from the largest trade creditors an offer to purchase the stock for £212. The offer would, however, probably be withdrawn if the estate were administered in bankruptcy. The matter was discussed at some length, and it was ultimately decided to confirm the deed already executed. The following are among the creditors :—Auto Claw Co., Ltd., £25; Cutting Bros., Ltd., £22; Everett Edgcumbe & Co., Ltd., £13; *Electricity*, £11; Ferranti, Ltd., £10; Adams Manufacturing Co., £7; Armorduct Manufacturing Co., £3; Drake & Gorham, Ltd., £6; Endolithic Manufacturing Co., Ltd., £3; General Electric Co., Ltd., £6; G.P.O. telephone, £1; London Electric Supply Corporation, Ltd., £1.

MISCELLANEOUS CITY NOTES

ADELAIDE ELECTRIC SUPPLY CO.—Notice is given to holders of preference share warrants to bearer that, on and after March 2nd next, they will receive payment of a dividend at the rate of 6 per cent. per annum for the half-year ending the 29th inst., less income tax, on presentation of Coupon No. 4 at the bankers of the company, Messrs. Glyn, Mills, Currie & Co., 67 Lombard Street, London, E.C. Coupons must be left with the bankers three clear days for examination.

BRUCE PEEBLES & CO.—A circular was issued on Saturday informing the shareholders that it has become necessary to call a meeting of the shareholders for the purpose of putting the company into voluntary liquidation, with a view to reconstruction. This step has been rendered necessary owing to the need of further additional working capital. A further issue of debenture was sanctioned by the shareholders in April, 1907, but by reason of the extreme stringency of the money market it was found impossible to make such an issue, and for the same reason it has not been possible to realise advantageously the securities in which the company is interested. The auditors are at present engaged on the preparation of the accounts, and the directors are considering plans for the reconstruction of the company, which have been submitted to, and favourably received by some of the larger creditors and representatives of the preference shareholders. A special meeting will be held on February 24th, when a resolution will be proposed sanctioning the voluntary liquidation of the company, and appointing Mr. A. W. Tait, liquidator, with a committee of shareholders and creditors. In a second circular which has been issued to the creditors, it is stated that under the proposed scheme it is expected that substantial payments on account will be made to the creditors at an early date. The circular further points out that in view of the large contracts in course of completion, it is absolutely necessary to carry on the business of the company without interruption, and the directors hope that the creditors will extend their support to a course of action which they believe will secure the best results for the creditors. Mr. J. A. Robertson Durham, of Edinburgh, has since been nominated as joint-liquidator on behalf of the creditors.

BOURNEMOUTH & POOLE ELECTRIC SUPPLY CO.—The directors recommend a final dividend at the rate of 9 per cent. per annum for the half-year ended December 31st, 1907, making 7 per cent. for the year.

BRITISH ALUMINIUM CO.—A resolution has been passed authorising the division of the £10 conversion shares into two shares of £5 each, one a 7 per cent. preference share, ranking *pari passu* with the existing 7 per cent. preference shares, and the other an ordinary share ranking with the existing ordinary shares.

CAMMELL, LAIRD & CO.—At a meeting of the directors last week, Mr. Arthur Daulby Wedgwood, late of the Dennystown Forge Company, was appointed Managing Director, and Mr. Henry Edward Deadman, C.B., late of the Admiralty, and Major Arthur Handley, late R.A., were elected directors.

CITY OF LONDON ELECTRIC LIGHTING CO.—A dividend of 6s. per share upon the preference shares for the half-year to December 31st, making 12s. for the year, and 7s. on the ordinary shares, also making 12s. for the year, has been declared. After making allowance for reserve, the sum of £20,000 is carried forward.

ELECTRICAL DEVELOPMENT COMPANY OF ONTARIO.—A Reuter telegram from Ottawa states that Mr. William Mackenzie, president of the Canadian Northern Railway, has secured control of the Electrical Development Company, bonds of which, to the amount of £1,600,000, are held in Great Britain. It is officially declared that the reorganisation will result in the interest being met.

Telegraph Traffic.—A lull has occurred in the storm of interruptions to telegraphic communication during the past week, but the repairs of certain cable lines, which we had hoped to be able to announce in this issue, have not yet taken place. It is probable, however, that during the coming week the cable between Trinidad and Demerara will be once again open for traffic. The company owning it have great difficulty in maintaining it in working order, owing to the injurious effect of the mud found on the coast of British Guiana, which it is said sets up chemical action leading to destruction of the cable. The only repair we have to announce this week is of the El Arich land-line route. The date of the Telegraph Conference at Lisbon has now been fixed for May 4th.

SUMMARY

A new enclosed flame arc lamp has been placed on the market. Passages are provided in order to obtain a good circulation of the gases, thus preventing eddies in the glass cylinder enclosing the arc. A plain carbon is used for the negative electrode, which is uppermost, and the positive carbon has a star-shaped section, and, instead of its being impregnated, paste containing the necessary chemicals is inserted in the grooves. (Page 299.)

A short description is given of a form of electric capstan with a loose head which can be connected to the spindle when required by a clutch. Several of these capstans are in use at Clydebank. (Page 301.)

Two Papers, both received from the Newcastle Local Section were discussed at the London meeting of the Institution of Electrical Engineers last Thursday. The first, by Mr. H. Henderson, describing the electrical equipment of the new goods warehouse of the North Eastern Railway, has already been published in our columns. The second, by Mr. C. E. Taylor, related to applications of electric power in docks, and described in some detail a number of coal conveyors and hoists, wharf cranes and capstans. Particular stress was laid on the advantages of Messrs. Stothert & Pitt's free-barrel device on cranes, which enables the load to be lowered independently of the motor armature, so that the change from lifting to lowering can be practically instantaneous, greater lowering speeds are possible than with a reversible motor, and the risk of overrunning can be lessened. An automatic starting switch for electrically-driven pumping plant was also described. In the discussion Mr. Roger Smith criticised the speeds of some of the cranes, and elicited from Mr. Henderson a complaint that the traffic department were apt to requisition unnecessarily high speeds for short lifts, the time occupied by which was but a small proportion of the total time taken in handling the goods. On the other hand, as a result of his reading the Paper, the under-hung jib travelling cranes described would be adopted on the Great Western Railway. He emphasised the economy of conveyors, such as those described by Mr. Taylor, compared with jib cranes, and pointed out that their load factor was far superior, giving the relative figures as 5·3 and 30 per cent. The design of electric capstans was severely criticised by Mr. Smith, Mr C. W. Neele, of the Great Central Railway, and Mr. C. F. H. Bayley, of the South Eastern & Chatham Railway, who all agreed that the resistances, &c., should not be placed in the capstan case, which is invariably damp, due to sweating. Mr. Smith even went to the extent of recommending that the capstan case should be lagged, and contain an electric heater. He also thought that series motors should

Digitized by Google

be employed rather than compound motors; but the contrary view was expressed by Mr. Henderson. Mr. Neele also referred to the trouble experienced with electrical devices to prevent over-running, and asked for a more sensitive controller. (Page 301.)

MR. P. DAWSON read a Paper recently at the Royal Automobile Club on "Railway Electrification," in which he gave a rapid sketch of the development and present aspect of the subject. Some prominent railway men took part in the discussion. (Page 307.)

A FIFTEEN-INCH "merchant" rolling mill at the Motherwell Iron & Steel Works is electrically driven on the slip regulation method by a 500 h.p. three-phase induction motor, at a consumption of about 40 Board of Trade units per ton of material rolled. An illustrated article describes the mill and the system employed, and also gives particulars of other electrically-driven plant used in the works. (Page 309.)

IN the discussion of Mr. J. F. C. SNELL'S Paper on the cost of electrical power supply, by the Leeds Local Section at Sheffield, further figures were given by various speakers. Mr. FEDDEN said that, in spite of the price of gas at Sheffield being about half the figure upon which Mr. Snell based his comparisons, the Corporation were adding to their power load at the rate of 200 to 300 kw. per week. Works that had previously put down their own suction and producer plants had changed over to the Corporation, and the load factor at which they supplied was now from 40 to 45 per cent. Mr. DICKINSON gave the diversity factor at Leeds as 2·4. (Page 312.)

A FORM of accumulator locomotive for use in mines, in which special attention has been paid to means for readily changing the batteries, has been developed on the Continent. (Page 313.)

THE Variable Electric Lamp Syndicate has obtained an injunction against the Bryant Trading Syndicate for infringement of a patent relating to a double filament lamp, in which the filaments are switched on and off by turning the lamp in its holder. (Page 314.)

A LARGE number of open inverted arc-lamps have been installed for interior illumination in the premises of a large West End drapery establishment. The lamps are fitted with under-reflectors, and in some cases with over-reflectors. The useful intensity of illumination is about three and a half candle-feet. (Page 314.)

THE working of the "Dick" voltage regulator, which is in use in the power-station of the Vienna-Baden single-phase railway and elsewhere is described. The voltage of the system is maintained constant by varying a resistance, which is in the field-circuit of the generator, or, in the case of alternating-current systems, in the field-circuit of the exciter, by means of a solenoid controlled switch acting by the displacement of mercury by a moving plunger. (Page 315.)

REVIEWS of the following books appear in this issue:—"Electric Arc Lamps," by J. Zeidler and J. Lustgarten; "The New Physics and Its Evolution," by L. Poincaré (translation). (Page 316.)

A PAPER on the electrical equipment of ships, read by Mr. W. D. KIRKPATRICK before the Liverpool Engineering Society, contains some interesting information concerning systems of wiring on board ship, and some comparisons between steam and electrical driving of auxiliary machines. An extract from an Admiralty specification for control gears, which must be made to operate in a similar manner to the old steam gear which it replaces, is given. (Page 317.)

A LETTER has been received from Mr. S. F. WALKER with regard to a short review of his book, published last week. (Page 318.)

IN the final of his series of Cantor lectures upon clock-making, at the Royal Society of Arts on Monday, Mr. H. H. CUNYNGHAME, C.B., dealt with electric clocks. He gave an interesting *résumé* of the history of this subject, and instanced examples of earlier electric clocks still doing good work. The main difficulty to be got over was with the batteries, the unsatisfactory nature of which, the lecturer said, was due to the impurities in the zinc. His own opinion was that the best form of battery would be a large gravity Daniell, using comparatively weak solutions. (Page 318.)

THE chief points discussed by Mr. HOULT in his Paper on "Direct-current Turbo-generators," read before the Manchester Local Section of the Institution, were the means provided for improving commutation, the use of carbon brushes for high-speed work and the balancing of high-speed rotors In the author's opinion, carbon brushes will entirely supersede copper brushes for high-speed work as well as for low-speed work. The discussion, in which several well-known engineers took part, turned chiefly on the superiority of compensating windings to the use only of commutating poles and the behaviour of carbon and metal brushes. (Page 319.)

A SERIES of tests on a boiler with and without a live steam feed-water heater have been conducted recently by Prof. GOODMAN and Mr. MACLACHLAN, the results of which are embodied in a Paper read last Friday before the Institution of Mechanical Engineers. The general conclusion arrived at was that, whereas in this particular case no great increase in the amount of water evaporated per lb. of coal was apparent, the deposit in the boiler was materially less when the feed-heater was in use. (Page 323.)

AT a meeting of the Birmingham Local Section of the Institution of Electrical Engineers on February 12th last, the Paper by Messrs. T. F. WALL and S. P. SMITH on the losses in pole-shoes due to armature teeth was further discussed. Mr. WALL'S Paper on the reluctance of the air-gap, originally read in Manchester, was also discussed at the same meeting. (Page 324.)

MR. G. FRANKLIN, presiding at the annual general meeting of the National Telephone Co. on Wednesday last week, dealt at length with the question of message rates *v.* unlimited service rates. He quoted some remarks of the Postmaster-General that some unlimited service subscribers who originally made 3,000 calls per annum had, in the course of a few years, increased this number to 11,000 per annum, using the same line. Mr. Franklin also stated that the National Company had many cases of flat-rate lines used to such an extent that 24 per cent. of the total calls had become ineffective owing to the lines being engaged. Some subscribers thought nothing of sending 250 or 300 calls per day, with the result that nobody else could get into communication with them. Moreover, it was peculiar to the telephone business that the larger the number of subscribers the greater the capital cost per subscriber, and the following illustration of this was given. With an exchange for 1,000 subscribers, the capital outlay on switchboards and junctions would be £4 per subscriber, but if there were 10,000 subscribers, the capital cost would be £13 per subscriber. (Page 324.)

UNDER "Electrochemistry and Electrometallurgy" we abstract an article upon the question whether the rusting of iron is a purely chemical or an electrochemical process. In this case actual potential measurements between unrusted iron and rusted iron and between cast-iron and wrought-iron were taken, and it would appear as if the rusting process could be described as electrochemical. We also briefly abstract the two Papers read before the Faraday Society on Tuesday. (Page 325.)

UNDER "Electrical Science" is given an account of Sir OLIVER LODGE'S Friday evening Lecture at the Royal Institution on "The Ether of Space." There are also notes in the British and American Section on the calculation of self-inductances and on phosphorescence produced by cathode rays. In the papers abstracted in the Continental Section W. RITZ formulates a new electromagnetic theory which eliminates the ether and propagates gravitation with the speed of light; STARK

Digitized by Google

explains the mechanism of band spectra; and Deininger studies the discharge from electrodes covered with quicklime. (Page 325.)

The Birmingham Corporation Tramways Committee have adopted the brake invented by Mr. A. W. Maley, of Leeds, which dispenses with blocks on the wheels, for three new tramcars, as an experiment. The Brentford Corporation have notified the London United Tramways Company that unless the tramway track in Brentford is put into a proper state of repair, an application will be made to the Board of Trade for an inspection with a view to enforcing the daily penalty of £5 stipulated in the company's Act. An application has been made to the Brighton Corporation for permission to run electric omnibuses. Complaints having been made by the Chiswick Corporation with regard to the smoke nuisance from the power-house of the London United Tramways, the Engineer to the company has replied that the apparatus which was installed some months ago with the object of preventing the emission of smoke has entirely failed, but that new precautions are being taken. A proposal which had been put before the Douglas (Isle of Man) Town Council to engage a consulting engineer to report upon the possibility of utilising water from the reservoir in connection with the electric lighting and tramways scheme, has been rejected. Sir Alexander Kennedy has been appointed to submit estimates to the Dunfermline Town Council upon the cost of erecting a generating station, or of taking a supply in bulk from the Fife Electric Power Co. At a conference of London Borough Councils owning electricity works, resolutions were passed which, it is stated, will affect the whole question of bulk supply in London in the future. The tramway system which Messrs. J. G. White & Co. have constructed in Luton has been opened. (Pages 327–329.)

At a local Government Board inquiry at Hanley on the 18th inst. the inspector, Mr. H. R. Hooper, agreed to the principle of sanctioning sums for prospective expenditure. A loan of £8,400 has been sanctioned to the Haslingden Corporation for the erection of a refuse destructor in conjunction with the Electricity Works. The Bradford Corporation tramways committee propose to spend £21,000 on the renewal of the track in various parts of the city. Tenders are invited by the London County Council for rails, and the Australian Government requires tenders for two cables between Tasmania and Victoria. (Page 329.)

The accounts of Messrs. Mather & Platt for the year 1907 show a net profit of £141,057. At the meeting of the Scarborough Electric Supply Co. last week, it was stated that an endeavour is being made to come to an arrangement with the Corporation for the erection of a refuse destructor in conjunction with the electricity works. A profit of £12,933 is shown in the accounts of the Simplex Conduits, Ltd., for 1907. The Telegraph Maintenance & Construction Co. accounts show a net profit of £165,470 for the year 1907. The accounts of the Charing Cross, West End & City Electricity Supply Co. show a net balance upon the West End undertaking of £42,023, and upon the City undertaking to £2,256. The connections to the West End undertaking are the equivalent of 538,964 8-c.p. lamps, an increase of 28,375 over the previous year, and the connections to the City undertaking are the equivalent of 457,757 8-c.p. lamps, an increase of 42,073. Mr. A. G. Lupton presiding at the half-yearly meeting of the Yorkshire Electric Power Co., on Wednesday last week, said the directors were now confident that the Company was fairly started on its way towards success. Sir William Crookes, presiding at the annual general meeting of the Notting Hill Electric Lighting Co., on Tuesday, stated that the company now paid rates equal to 2¼ per cent. per annum upon their share capital, and that advice was being taken with a view to an appeal against the assessment. At the meeting of Messrs. Bruce Peebles & Co. on Monday, when a resolution agreeing to voluntary liquidation was passed, it was stated that the net loss was £93,671. (Pages 331–333.)

The London Electric Supply (Joint Committee) Bill has been read a second time in the House of Lords. Three tramways Bills affecting London have been referred to the Standing Orders Committee for non-compliance with Standing Orders. (Page 333.)

Three patent specifications relating to incandescent lamps by the British Thomson-Houston Co. were published on Thursday last. The first describes the preparation of a filament composed entirely of tungstous oxide, which, it is stated, has a longer life than the ordinary metallic tungsten filament. The other two refer to filament supports and treated carbon filaments respectively. Another specification by the same company describes a single-phase repulsion motor without a commutator, which has the characteristics of a direct-current series motor. The Lancashire Dynamo & Motor Co. have patented a method of control for flywheel motors working on an intermittent load. (Page 335.)

Two Papers of considerable interest both to railwaymen and to electrical engineers were discussed at the Institution of Electrical Engineers on Thursday last. Their subject was the use of electrical power in the goods warehouses and docks of the North Eastern Railway. The Tyne has the advantage of a very cheap supply of electricity for power purposes, and the North Eastern Railway have made wise use of this opportunity in displacing worn-out hydraulically-worked plant by electrically-driven plant. Their fine new goods warehouse in New Bridge Street has been equipped with electrically-driven machinery throughout, while at their Tyne Dock old hydraulic pumping machinery and boilers have been replaced by electrically-driven hydraulic pumping machinery to work existing hydraulic plant more economically. The Papers were almost exclusively descriptive. Some of the apparatus described is new and some old, but all of it is more or less interesting. It is necessary to remember that almost all railway machinery in goods warehouses is worked by the Traffic Staff and not by the Engineering Staff. It must therefore be simple to manipulate, and, since repairs will probably not be asked for until a complete breakdown occurs, designs ought to be such as to make repairing work by the mechanical staff as easy as possible. In the discussion, the speeds of the various cranes described were adversely criticised, some being much too great where very short lifts were in question, and others for high lifts being too slow. The Traffic Department who work the machinery usually specify the speeds, but it is essential that those who specify the machinery should clearly point out to the Traffic Department whether the speeds asked for are those which give the most economical results. In Mr. Henderson's Paper on electrical power in goods warehouses, and in the discussion, the present design of electric capstans was severely criticised, and there is no doubt that manufacturing firms who make this plant have been content for far too long to produce machinery which almost always gives trouble, working as it does under the most adverse circumstances. One point in the discussion which appeals to us as of value was the suggestion that all capstan electrical switchgear should, if possible, be removed from the capstan-box and be put in a totally enclosed and accessible case or pillar above ground. One of the many valuable features of electric driving, quite apart from efficiency, is the means

Digitized by Google

it affords of making fairly accurate comparisons of the power required by different pieces of plant or machinery. This leads to questions of efficiency being discussed, which previously were frequently overlooked. For instance, in the present debate the use of conveyors and cranes for loading coal into vessels was compared, and the great saving which is arrived at by employing the former method was made apparent. A hinged belt conveyor for delivering coal into vessels alongside, at any state of the tide, described by Mr. TAYLOR in his Paper on electric power in docks, showed that in actual working, about 500 tons of coal per hour could be delivered into a vessel, requiring the continual work of a 16 h.p. motor. With a lifting and tipping coaling crane less than half the above quantity of coal required the intermittent use of 120 h.p. in the hoisting and slewing motors. The discussion brought out that one of the fairly modern type hydraulic coal-tips in a South Wales dock required, for a delivery of 400 tons of coal per hour, the intermittent use of 50 pump h.p. at the tip-rams, for which about 100 indicated h.p. was installed in the pumping station. It was further mentioned that at Fishguard Harbour the annual load factor of 11 electric wharf cranes was slightly more than 5 per cent. It seems likely, therefore, that the advance in the economical shipping of unpacked materials in bulk, such as coal or ore, will be in the direction of the use of conveyors rather than in the use of tipping hoists or special cranes. The electric motor is the ideal drive for a conveyor of any form, while the load factor of such machinery as compared with the load factor of cranes or hoists is so incomparably better that it would seem worth while for electrical engineers to give especial attention to this class of machinery, and to urge its adoption on railway and dock people wherever conveying is suitable.

A NEW arc-lamp, combining the advantages of the flame arc with those of the ordinary enclosed arc, is described on another page, and if it confirms in practice the claims made by its makers, it should have a future before it. This new "Jandus" lamp follows the same lines as the Blondel flame lamp. The carbons are arranged vertically, with the positive carbon underneath, and a system of passages for ensuring a circulation of the gases and fumes is common to both the above lamps. Comparing the new lamp with the illustration contained in the Blondel patent (ELECTRICAL ENGINEERING, Vol. I., p. 521), the chief difference apparently lies in the construction of these passages; and from an article on the commercial form of the Blondel lamp as made by Messrs. Crompton & Co. (ELECTRICAL ENGINEERING, Vol. II., p. 853), it appears that impregnated carbons are employed in this, while in the Jandus lamp the carbons are high-grade carbons, the upper one plain and the lower one of a star-shaped section with the necessary chemicals, supplied in the form of a paste, set in its interstices. It is gratifying to see that arc-lamp makers are continuing to exercise the inventive energy and constructional ability that is maintaining the arc-lamp well in advance of the incandescent gas burner for the illumination of streets and large spaces.

THE electric driving of rolling mills is gradually gaining ground in this country, and the description which we publish this week of the 15 in. "merchant" mill driven by a 500 h.p. motor will be read with considerable interest, chiefly on account of the simplicity of the method employed for regulation. While the flywheel motor-generator would appear to be a *sine quâ non* in the case of reversing mills, the present installation shows that a more direct method of control is applicable with good results to ordinary rolls. A three-phase induction motor is employed, and, when the heavy load comes on, a resistance is inserted in the rotor circuit, increasing the slip between the phases of the stator and rotor, and the decreased speed causes the flywheel to give up some of its energy into the mill. The efficiency of the arrangement should be high, and the simplicity is such that, in addition to the general economies brought about by electric driving, there should be considerable saving in the cost of labour and maintenance. Electric power companies and those makers of electrical plant who are the most alert for an increase in their field, should now be looking to iron and steel works as one of the most important class of customers in the near future, and if the few examples of electric rolling-mill drive in this country give satisfaction to the mill-owners, a large increase of work will doubtless accrue to the electrical engineering industry.

WE were pleased to hear the announcement made by the PRESIDENT at the last meeting at the Institution of Electrical Engineers that a movement is on foot among electrical men to establish a memorial to Lord KELVIN. A committee with this object has already been formed and has recommended that a Kelvin lectureship be established by the Institution, and a Kelvin lecture held annually. It is also proposed that steps be taken to place a statue of the Institution's greatest President in a prominent position in London, and that, if possible, a series of scholarships shall be founded. The fame of so great a man will continue to live by his own monumental works, apart from any reminder erected by his followers; but not only do we heartily approve of the scheme of invoking the sculptor's art to give enduring expression of the respect felt for their leader, but we particularly applaud the recommendation to establish means of furthering the knowledge of the subjects upon which his work had so much influence, and of assisting aspirants to his field of thought and action.

ARRANGEMENTS FOR THE WEEK

FRIDAY, FEBRUARY 28TH.

Physical Society.

5 p.m. Meeting at the Royal College of Science, Imperial Institute Road, South Kensington. Paper to be read:—"Contact Potential Differences Determined by means of Null Solutions." By S. W. J. Smith and H. Moss.

SATURDAY, FEBRUARY 29TH.

Institution of Electrical Engineers: Students' Section.

10 a.m. Visit to the Brimsdown power station of the North Metropolitan Electric Power Co.

TUESDAY, MARCH 3RD.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, London. Paper to be read:—"Notes on Some Engineering Works in Austria and Bosnia." By A. S. E. Ackermann.

Tantalum Lamps for Alternating Current.—Messrs. Drake & Gorham inform us that a tantalum lamp, suitable for alternating current, will be placed upon the market in a few days. Up to the time of going to press we are unable to obtain particulars as to candle-power, &c., either from Messrs. Drake & Gorham or Siemens Bros.' Dynamo Works, but we understand that a pamphlet on the subject will be available by the end of the week.

Digitized by Google

THE JANDUS ENCLOSED FLAME ARC-LAMP

In the ordinary enclosed arc lamp, as is well known, access of oxygen to the arc is prevented by enclosing the electrodes in an air-tight chamber. The burning of the carbons is thus considerably retarded, and providing the carbons are of a high grade and contain no impurities, this arrangement is very satisfactory. When the flame-arc was first introduced, attempts were made to enclose the arc for the same purpose, but these were not successful, as most of the light given out by the ordinary flame-arc is due to the actual combustion in the arc of the chemicals with which the carbons are impregnated. Consequently when the oxygen present in the enclosure was exhausted, the arc lost most of its brilliancy; and, furthermore, the products of the combustion and the other residues from the chemically-impregnated carbons were desposited on the globe, thus causing most of the remaining light to be absorbed. The Jandus "Regenerative" flame lamp has been especially designed to overcome these objections, and in two points is entirely new. In the first place special means are provided for obtaining a circulation of the gases past the arc, and secondly the light is mainly produced by raising certain gases to the temperature of incandescence, and not by the combustion of chemicals in the arc. The spectrum of the light from the arc is a band and line spectrum, showing that the gases are incandescing.

Fig. 1 shows the mechanism of the lamp, which is the same as is used in the ordinary Jandus single enclosed arc lamp. The lower carbon, which is the positive, is held in a fixed support. Surrounding the arc is a clear glass cylinder, and outside this again is a translucent globe. This arrangement of the carbons gives a wider distribution of light than the usual arrangement, in flame arc lamps, of converging carbons, which was necessary in order to keep the striking contacts of the electrodes free from slag. The inner glass cylinder is in communication with two metal tubes, one on either side of the globe. These tubes, shown in section in Fig. 1, are also conspicuous in Fig. 3. There is a circulation of the hot gases up the central cylinder and down the outer tubes, and the incandescing gases are carried round and subjected to the high temperature of the arc several times before finally condensing and settling in the outer tubes. (This arrangement is protected by British Patent No. 23,286, 1906.) It was for this reason that the name of "regenerative flame arc lamp" was given to the lamp.

The inner glass cylinder is kept perfectly clear of deposit for the greater part of its length, chiefly as a result of the high temperature which prevents the gases condensing, and also probably on account of the direct and strong draught past the arc. In the outer tubes the gases are condensed, partly because of the lower temperature, and also possibly as a result of the formation of eddies in the tubes. These outer tubes and the support for the outer globes are cast in iron or aluminium in one piece, as is seen from Fig. 1. The upper negative carbon is an ordinary high-grade carbon. The lower carbon is also of high-grade carbon, but is

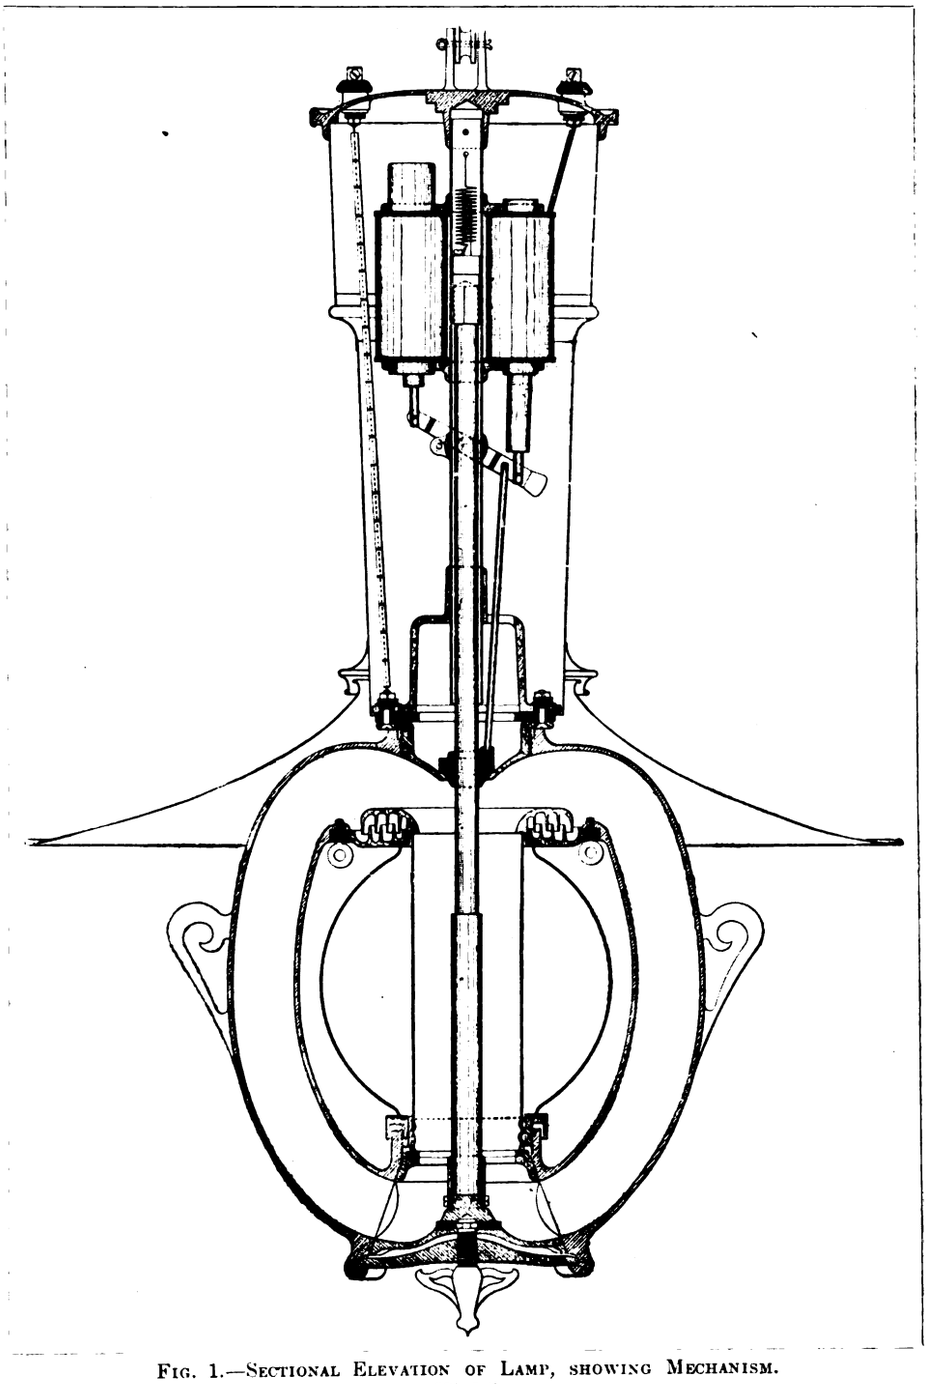

Fig. 1.—Sectional Elevation of Lamp, showing Mechanism.
One-fifth full size.

D

Digitized by Google

star-shaped in section. The grooves between the eight rays of the star are filled with a chemical composition, which is laid in in the form of a paste. The rods are then baked, and the paste expands into the pores of the carbon and fixes itself firmly into the grooves. The carbons themselves are not impregnated, although this was tried at first. When impregnated carbons were used instead of the arrangement described above, the slag produced by the chemicals covered the carbon-tips and prevented the arc from forming. By the use of the star-shaped carbon the central tip of the carbon is always clean. About 15 grains of the composition are volatilised every hour, the gases rising up from the positive crater through the arc. The arrangement of the carbons and enclosing globes gives a most favourable distribution of light, as can be seen from the curve of Fig. 4. The life of a single pair of carbons is over 70 hours. The light is a yellow-white colour, but modifications can be obtained by varying the nature of the composition on the positive carbon. No shadows are thrown by the outer metal tubes on account of the diffusing properties of the outer globe, and the appearance of the lamp is improved by covering the tubes with vitrified enamel. Fig. 2 shows the illumination given by a lamp hung 30 feet from the ground, at various distances from the lamp-post. The trimming and cleaning of the lamp is a very simple process, as the outer globe is not removed. By loosening the wing-screw at the bottom of the lamp the conical plug can be removed, and with it the inner cylinder and the lower carbon. We are informed that the 550-watt size taking 5·5 amperes at 100 volts, gives a mean hemispherical candle-power of 2,200. The regenerative flame arc lamp is the invention of Mr. A. Denman Jones, the manager of the Jandus Arc Lamp Co.'s works. The lamps are manufactured entirely at the Jandus works in Holloway, and are put upon the market by Messrs. Drake and Gorham, Ltd.

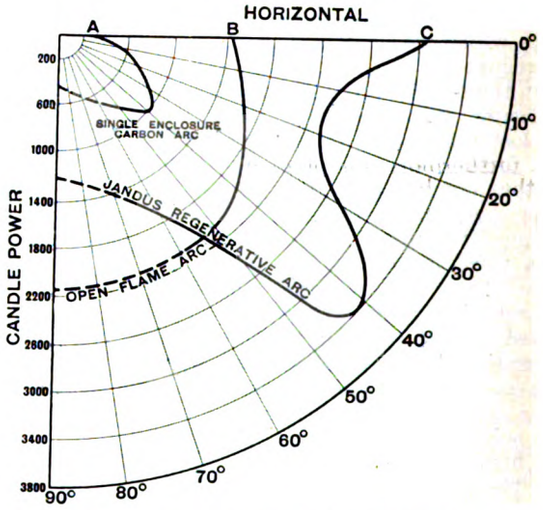

FIG. 4.—COMPARISON OF CURVES OF DISTRIBUTION OF LIGHT.

Students' Dinner.—The fourth annual dinner of the Students' Section of the Institution of Electrical Engineers was held at the Holborn Restaurant on Monday last. Among the guests were Prof. S. P. Thompson, Mr. W. M. Mordey, Mr. R. Hammond, and Mr. A. O. Laird (Chairman, Graduates' Section of the I.Mech.E.). The toast of "The President and the Institution" was proposed by Mr. C. C. Abell (Vice-Chairman of the Students' Section), and responded to by Mr. W. M. Mordey, who said that he was sorry to hear that the students' meetings were not well attended. Commercial papers especially were shunned, and this was a great pity. He emphasised the importance of these meetings, especially with regard to the opportunity they afforded for friendly intercourse amongst the students. In his opinion it would be a good thing if estimating classes were arranged for in the colleges. Estimating and drawing were, he thought, subjects to which engineering students should give particular attention. Mr. Hammond, in proposing the toast of the Students' Section, advised the students to cultivate the habit of curiosity. Curiosity, he said, was a mark of civilisation, and by curiosity all knowledge was built up. Mr. E. W. Moss (Chairman of Students' Section) responded, and in the course of his remarks said that a visit to Newcastle was being arranged for next July. The toast of "The Colleges," proposed by Mr. B. A. Cooper, was responded to by Prof. S. P. Thompson, who also urged the students to attend the meetings, and hoped that there would in future be more harmony between the different institutions. Good, honest, frank rivalry was an excellent and admirable thing, but at the same time the students should learn to work together with a harmony of purpose and a unity of desire. With regard to Mr. Mordey's remarks, he (Prof. Thompson) thought that the commercial side of engineering was better learned in commerce than at college, but he had already introduced the question of cost into his classes on dynamo design, and had found that the students took a keener interest in the work at once. It gave a reality to the work, which was most valuable.

THE CLYDE PATENT ELECTRIC CAPSTAN

THE accompanying illustrations show a type of electric capstan, differing markedly from the forms more usually adopted hitherto in essential points of design. It has been developed under the patents of Mr. Walter Dixon and Mr. G. Baxter, and a number of examples of it have been manufactured by Messrs. Stothert & Pitt, of Bath, and supplied to the Rothesay Dock of the Clyde Navigation Trustees.

The principal features of the capstan, as will be seen from the drawing, are that the head is not fixed to the spindle, but is connected thereto by a clutch sliding upon the upper end of the spindle inside the capstan-head, and that a wire rope is used, permanently fixed to the capstan-head, instead of the usual loose hemp rope passing through the man's hand and given a few turns round the head. All the gear is machine-cut, and runs in oil, ball bearings being fitted to the capstan-head and also to the worm-shaft to take end thrust. When the gear is at rest, the head is loose upon the spindle, and a wire rope fixed to the head can therefore be used, a positive pull being obtained as soon as the head revolves, thereby avoiding all losses due to current consumption when the head is running light at starting. Moreover, as the rope is fixed, there is no slipping and grinding action upon the head as where loose hemp ropes are used, and the head may be made of cast-iron without fear of wear.

The starting-switch and clutch are controlled by a long lever, which, in the backward position, releases the head by throwing out the clutch, and in the other direction puts in the clutch and operates the starting-switch. The man is thus free to work his starting-switch in an upright position and see all that is going on, instead of having one foot and two hands occupied. In places where a number of wagons have to be drawn up and used one at a time as in a coal hoist, this is a very good arrangement; there is a great saving in ropes, and no wear on the capstan head.

The makers have conducted a number of comparative tests, from the results of which they claim that under varying loads an overall average efficiency can be obtained ranging from 42 to 78 per cent., according to circumstances, as compared to a corresponding figure of 10 to 32 per cent. for hydraulic capstan of modern design. Also, from a large number of observations taken, it has been found that the standard capstan with loose rope makes about three times the number of revolutions of the Clyde capstans to perform the same work, owing to the large number of useless revolutions of the former when the rope is not on the head, or is slipping. Comparative current consumption curves have been made which show a reduction of 25 per cent. in favour of the Clyde capstan as against a standard electric capstan with fixed head, and a reduction of 50 per cent. in the peak of the load demand upon the generating station.

PLAN AND SECTION OF CLYDE CAPSTAN.
Scale: 1/32nd full size.

ELECTRIC POWER IN RAILWAY GOODS WAREHOUSES AND DOCKS

TWO Papers were read in abstract and discussed at the meeting of the Institution of Electrical Engineers in London on Thursday last. The first, by Mr. H. Henderson, had already been read and discussed before the Newcastle local section. It described the equipment of the North Eastern Railway Co.'s new goods warehouse at New Bridge Street, Newcastle, which includes interesting forms of overhead jib, and other cranes, capstans and wagon hoists. The Paper and discussion in Newcastle were reported at length in our issue of January 16th.

The second Paper was by Mr. C. E. Taylor, on "Electric Power in Docks," and it had also been received from Newcastle, where it was discussed on Monday, a few days after the London discussion.

Mr. Taylor first referred to the great extension in the use of electrical power in docks during recent years. Electricity offers many advantages over the hydraulic system (which has up to recent times held this field almost exclusively), especially in places where electric power can be obtained at a reasonable rate from an outside source, and the user has not to incur the heavy capital expenditure involved in the provision of a generating station for the exclusive supply to the dock premises above. His opinion is that, where a reliable supply can be obtained from an outside source, as in the Tyne district, it is much more advantageous to take supply from that source than to generate for such loads as are obtained in docks where the total consumption is small and the maximum demand large. The installation cost for distribution is small compared with that for a hydraulic supply, and not so liable to failure, whilst the consumption is proportional to the work done. The efficiency of electric machinery is necessarily much higher than that of hydraulic plant for the same purpose, especially that of the older type, and the distribution is more flexible and lends itself more readily to alterations and additions.

At the North-Eastern Railway Co.'s dock—Tyne Dock—the steam pumping plant, being old, is being replaced by electrically driven pumps, with the intention of gradually replacing the hydraulic cranes, &c., as necessity arises, by electric plant also

COAL CONVEYORS.

The difficulty of loading bunker coals into vessels when light from the older jetties or staiths has led to the adoption of special apparatus capable of running the coals on the level or on an inclined plane. One form of this apparatus is shown in Fig. 1. Coal conveyors have recently been brought into use at the North-Eastern Railway Co.'s dock at Tyne Dock. The arrangement consists essentially in making the spout into an endless belt conveyor, coals being shipped at low level, and run over the belt in the ordinary way. When shipped into vessels, level with the spout, or above it, the latter is adjusted as may be required, and the belt run by an electric motor, the coals

Digitized by Google

being carried along until they reach the hatch, when they drop over into the hold. The belt spout can be adjusted to any angle, but the useful maximum is about 25°, and at this angle some 500 tons can be shipped by each conveyor per hour. Some experiments have recently been made on these conveyors, and it was found that the average power working at full load on a slight inclination was 12 h.p., and the consumption during the test was 7 units, with a total quantity of coal shipped, equal to 410 tons, giving an average per ton of 0·017 unit. Whilst the test was in operation some further experiments to show the power absorbed with various inclinations of the belt were made, with the curious result of a constant absorption of power for any inclination was obtained. Practically the power remained constant at 12 h.p., and it was found that the belt automatically regulated the quantity of coal carried according to the inclination. This was a result that had never been anticipated.

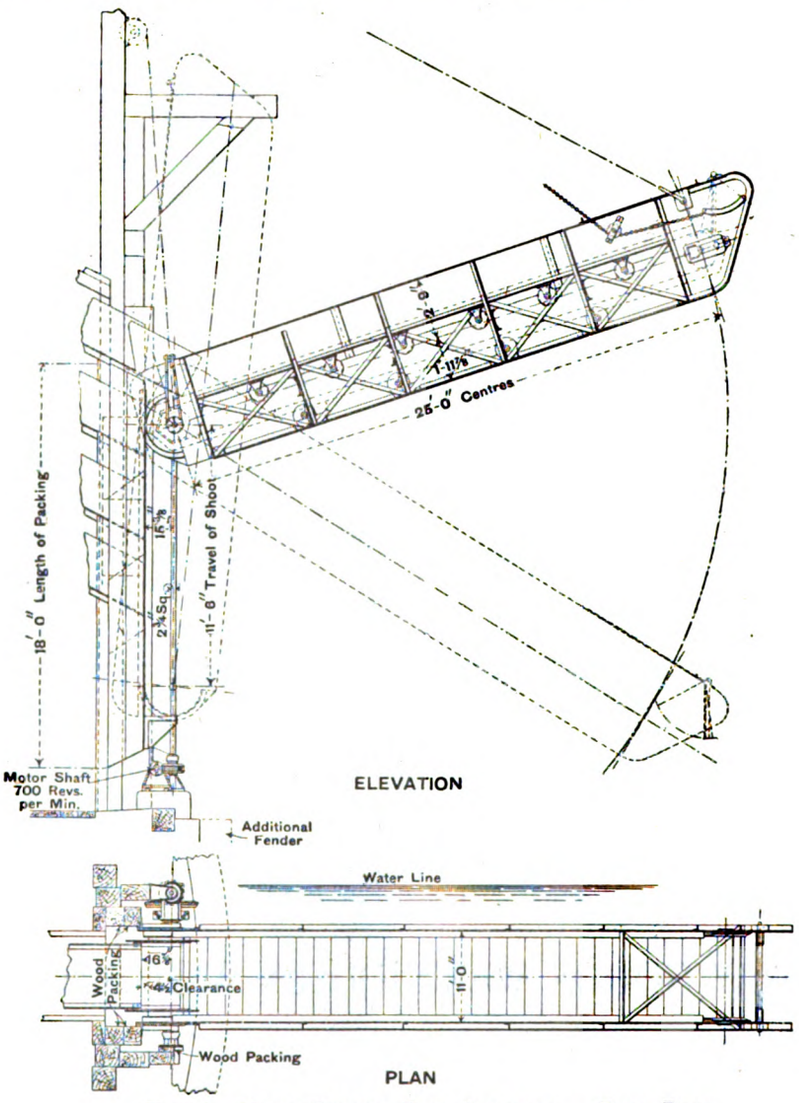

FIG. 1.—MOTOR-DRIVEN COAL CONVEYOR. TYNE DOCK.

A three-phase motor, capable of developing 16 b.h.p. at a speed of about 800 revs. per minute, drives the spout by a suitable reduction gear at a velocity of 120 ft. per minute. A margin between the average absorbed, and the total power of which it is capable, is allowed for cases where the belt is required to start with a considerable amount of coal upon it, or to take the load if coal is dumped upon it very freely, as often happens.

The arrangement is extremely efficient for the purpose for which it is intended; no other motive power could have been used in this case, and the adoption of the system has obviated the necessity for reconstruction of the staiths for a very considerable time. In this way there has been a great saving on capital expenditure.

ANTI-COAL BREAKER.

The more modern staiths for shipping coal at North Blyth have shown another defect which the use of electric power has done much to remedy. The staiths are very high, and coal has a long way to drop into the holds at low tide, with the result that much coal is broken, and its value is diminished thereby. The anti-coal-breaker arrangement consists essentially of a system of buckets balanced to run over the suspended shaft, the whole being suspended from the jib of an electric crane fixed on the upper part of the staith. Coal from the ordinary spout is run into the buckets on one side of the chain, and these are carried by gravity into the hold of the vessel, where they are emptied and the buckets begin the return movement. The whole arrangement is clearly shown by Fig. 2. The jib crane is capable of carrying 8½ tons, and the lifting and slewing motors are 20 and 8 b.h.p. respectively. The lifting speed is 25 ft. per minute. As will be seen from Fig. 3, the speed of the bucket chain is capable of being regulated by an automatic centrifugal brake to a velocity of 120 ft. per minute.

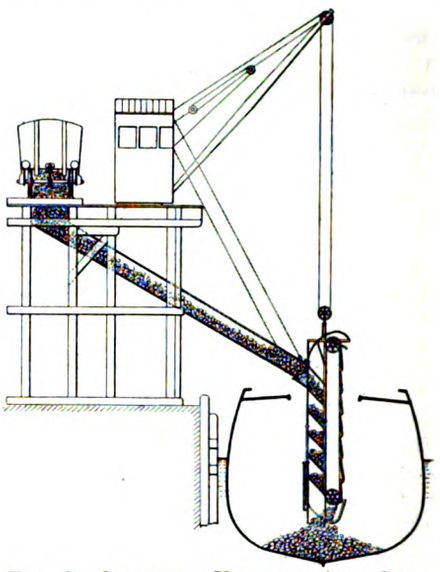

FIG. 2.—SECTIONAL VIEW OF ANTI-COAL BREAKER, SHOWING METHOD OF OPERATION.

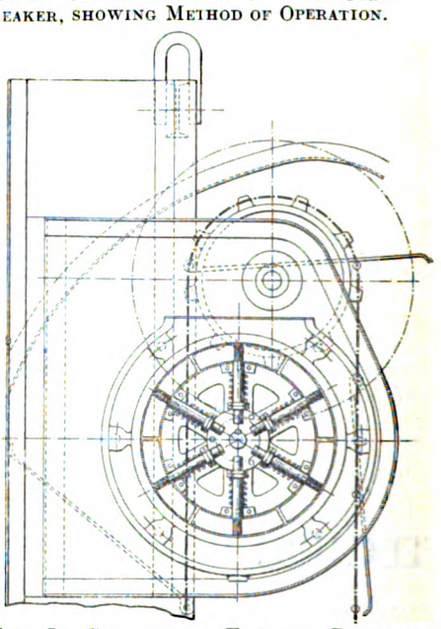

FIG. 3.—CENTRIFUGAL FRICTION BRAKE FOR AUTOMATICALLY CONTROLLING SPEED OF ANTI-COAL BREAKER.

COAL HOISTS AND COALING CRANES.

In cases where the ground-level is low, coal hoists are used to a great extent and also coaling jib cranes. With regard to coal hoists this is a field in which hydraulic machinery has hitherto been universally adopted. The wagons are raised by a hoist and tipped by means of another ram attached to the platform, the wagons being fitted with end doors; the wagon is then lowered again and the platform lowered to a high-level empty wagon road, where the wagon is run off and the platform lowered to the ground-level for another full wagon. Electrically driven coal hoists, which perform exactly the same

Digitized by Google

operations, have recently been erected at Rothesay Dock, Clydebank, by the Clyde Navigation Trustees.*

In some cases coaling cranes are displacing hoists, or are being provided as additions. A typical example is the 25-ton crane installed on Humber Dock Quay, Hull. The lifting is done by two 50-b.h.p. motors, both coupled to the same shaft, and controlled by a series parallel controller—the tipping motor is 50 b.h.p., and the slewing motor 20 h.p. Fig. 4 shows the arrangement of the ropes for lifting and tipping the wagons, the slack of the tipping rope is taken up by another barrel, which is geared to the lifting barrel, the rope being taken over a pulley which is fixed to two square thread screws. These screws are driven by the tipping motor and draw the pulley backwards

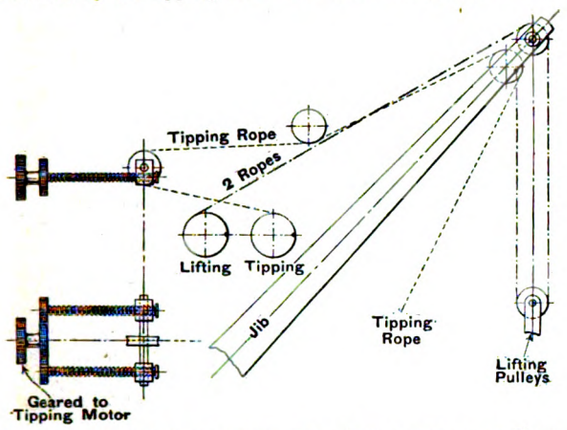

FIG. 4.—DIAGRAM SHOWING THE ARRANGEMENT OF LIFTING AND TIPPING ROPES FOR 85-TON ELECTRIC COALING CRANE.

and forwards, thus effecting the tipping motion. The radius of this crane is 31 ft., the height of jib from road-level is 50 ft., and the approximate amount of coal which can be shipped by this crane is 230 tons per hour.

WHARF CRANES.

For loading and unloading material of a general kind, and iron ore, &c., cranes of a high gantry type are in universal use. These cranes take up a minimum amount of space on the quay, and allow wagons, &c., to pass under them. In cases where a warehouse is built on the quay, a slight alteration is made by having one side of the gantry running on the quay wall, and the other running on a girder let in to the building. This still enables wagons to pass under the cranes as before.

Cranes of the high gantry type are in use at various docks, those at Middlesbrough and Hartlepool, on the North-Eastern Railway Co., being capable of lifting 10 tons and 3 tons at 150 ft. per minute, 1½ tons at 250 ft. per minute, and slewing at 400 ft. per minute. The jib radius is 45 ft., and the height of the jib top from the quay-level is 60 ft. The hoisting gear is driven by a 50-h.p. motor at 300 revs. per minute, and is geared direct to the barrel.

On the motor shaft is fixed a band brake operated by a special electromagnet in series with the armature of the lifting motor. The two poles of the magnet are similar to a small two-pole dynamo with upright poles, and revolving between them is a solid steel armature, connected by a lever to the brake, which is held on normally by weight. When the fields are excited and motor is started this armature turns through 90°, and raises the weight, thus releasing the strap. The brake can also be operated by a lever near the controller, so that lowering can be carried out without the power being applied to release the brake. The slewing gear is driven by an 8-b.h.p. motor at 1,000 revs. per minute, coupled to which is a worm driving a worm-wheel. This gears with a spur-wheel on a vertical shaft, carrying the driving pinion, which engages with a circular rack fixed on the top of the gantry.

The motor is controlled by a foot brake on the motor spindle. The cranes revolve on twenty-four cast steel rollers. A universal controller is used for both motors. The collector gear is fixed to a pillar in the centre, and cables pass up the centre column, and are attached to two rings mounted on ambroin, upon which are brushes fixed on porcelain insulators attached to the cabin floor, and from which wires pass to the controller.

The cranes are moved along the quay wall by a 4-b.h.p. motor at 30 ft. per minute, the gearing being arranged for hand working if necessary, each side being driven by means of a cross-shaft and bevel wheels. Current is taken from underground mains on the quay, which are connected at intervals of 50 ft. to plug boxes. The crane plug is bell-shaped, to prevent water entering the boxes whilst the cranes are in use, and can only be attached in one way, so that the correct motion is obtained.

The 10-ton cranes are of the same design as the 3-ton cranes. The lifting motor is 60 b.h.p., and the revolving motor is 12 b.h.p. The lifting motor in single gear drives directly through a pinion on to the barrel, the ratio being 8 to 1, and a double part of rope is used. With single gear loads up to two tons are lifted, and double gear is provided for loads over two and up to ten tons.

When lowering, the motor is driven by the weight, but a new device is now in vogue on similar cranes, patented by Messrs. Stothert & Pitt. The lifting barrel is not keyed directly to the shaft, but runs loose on it, and is connected or disconnected by a friction clutch. The barrel shaft carries the main spur-wheel rigidly keyed on to it, and this spur-wheel gears directly by single reduction with the pinion attached to the armature spindle of the lifting motor. The hand lever actuating the lifting controller, also actuates an electric solenoid which controls the lifting friction coil clutch, the arrangement being such that on moving the lifting handle forward from the off position, current is switched on to the solenoid, the clutch is put into gear, and the lifting motor started simultaneously; after the clutch is in gear, a further movement of the lever cuts out resistance and speeds up the motor. Provision is also made of a mechanical connection between the lifting controller handle and the coil friction clutch as an alternative to the electric solenoid. A large friction brake drum is keyed directly on to the lifting barrel, the brake strap being lined with willow blocks. The lifting controller does not reverse the motor, as the lowering is carried out independently by the loose drum.

The great advantage of this arrangement is the large increase in speed of working, both in lifting and lowering, and also the reduced liability of accident to the motors, owing to the impossibility of suddenly stopping the armature. In cranes with the barrels always in gear with a reversible motor, care has to be taken to check the lifting motor when the hook is a sufficient distance from the jib head, so that the momentum of the revolving armature may be absorbed before the hook is overwound on the jib pulley, with the possible result that the jib itself is lifted and the tie rods bent. With the system described above, lifting can be continued at full speed, and the load brought to rest instantly by pulling over the handle, the only revolving parts which have to be brought to rest being the barrel and brake drum, which have comparatively small inertia and do not revolve at an excessive speed. The great gain in

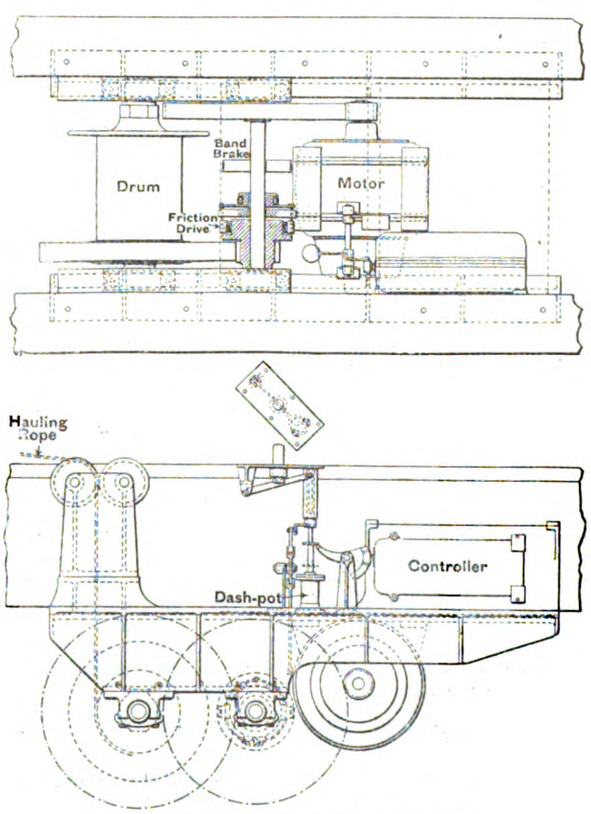

FIG. 5.—UNDER-DECK TYPE CAPSTAN.

* See *Electrical Engineering*, vol. ii., p. 747.

Digitized by Google

speed is in lowering, which can be performed at a vastly greater speed than is possible by a reversible motor, there being a perfectly free run out under the control of the foot brake, and what is of equal importance, lowering can be commenced instantly without perceptible pause from lifting at full speed; the lifting armature can continue to revolve with slackening speed during the period of lowering, and then comes to rest quietly without shock. As a matter of practice it is found that a load can be lowered 60 ft. before the armature has ceased to revolve.

CAPSTANS.

Under this head, the author first referred to the special capstan at Rothesay Dock, a detailed description and drawing of which appears on another page. Electric capstans, he added, can be fitted in many cases where other forms could not be used. On the North-Eastern Railway Co.'s staiths at Dunston an under-deck type of capstan, fixed entirely under the floor of the staiths is being experimented with. In this case the capstan is not furnished with the usual head, but the rope is carried round a horizontal drum. This type of capstan is shown by Fig. 5. The motor is a 30-b.h.p. three-phase motor, running at 770 revs. on a circuit of 440 volts 40 ~, and drives by means of a pinion a first shaft which has fixed upon it a friction drive for operating the barrel shaft. The barrel has on it a fixed rope which passes over the horizontal drums placed level with the floor of the staiths, so that the rope may work in

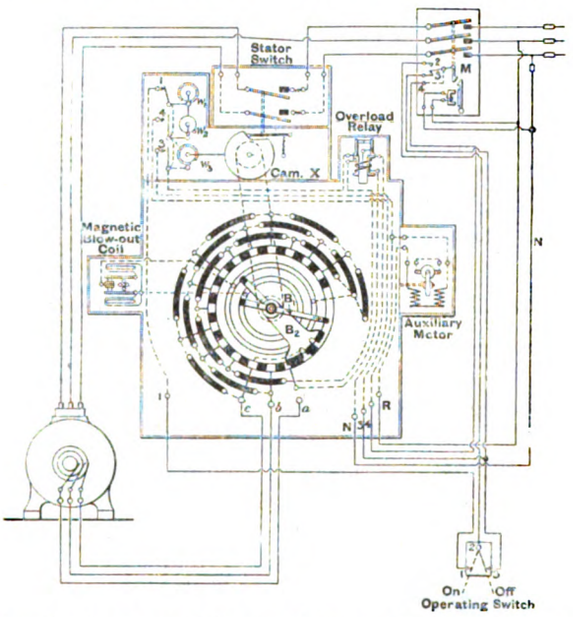

FIG. 6.—AUTOMATIC 3-PHASE STARTING SWITCH. DIAGRAM OF CONNECTIONS.

either direction as required for hauling purposes. The method of working is such that, when the treadle is depressed, the stator is made alive, and the motor brought up to speed by cutting resistance out of rotor circuit; at the same time the band brake is released, the friction clutch engages with its drum, and the rope is wound round the barrel. When the treadle is released the clutch allows the rope barrel to stop immediately, and the momentum of the motor is pulled up gradually by the band brake. This is a very essential point, as the wagons are drawn down a slight decline over the cross-over roads to the spouts, and each wagon must be stopped immediately over them; otherwise, if they run past, the whole train of wagons must be hauled back up the gradient. The motor is only operated in one direction, the drum running freely when slack rope is needed, which is drawn off by hand as required according to the number of wagons to be hauled.

ELECTRIC-DRIVEN HYDRAULIC PUMPING PLANT.

Any new dock which may be built would probably be fitted with electrical power throughout, as at Rothesay Dock,* Fishguard,† &c., but it cannot be expected that the hydraulic plant in use at an old dock should be pulled out and replaced by electrically-driven machinery until worn out. An improvement can, however, be made by installing electrically-driven hydraulic pumps supplied by power from a power company, and working these automatically.

* See *Electrical Engineering*, vol. i. p. 747, and vol. ii. p. 730.
† See *Electrical Engineering*, vol. i. pp. 385 and 433.

A change of this kind is at present being made at Tyne Dock, where three engines and five boilers are being replaced by four electrically-driven pumps with three-phase motors of 132 b.h.p. each. These drive three-throw crank pumps through a flexible coupling. Each motor is provided with a three-phase automatic starting switch driven by a small motor $\frac{1}{12}$ h.p., which is connected between two of the phases and brought into action by a switch attached to the accumulator.

Fig. 6 shows a full diagram of connections for this starting switch, the method of working being as follows:—Each automatic switch is connected to the mains through a three-pole switch M, which has a no-voltage release, and is fixed on a separate switchboard. From this switch one main passes direct to the motor, whilst the other two pass through a magnetic blow-out switch fixed to the auto-starter, and operated by cam X. The circuit for working the auxiliary motor is coupled to two phases on the live side of switch M.

Current passes along wire N, through overload relay, to cams marked W_1, W_2, W_3, which make and break contact with points 1, 4, and 3, as required. In starting, current passes down No. 1 to the operating switch on the accumulator, and as the accumulator is down passes to No. 2 on the switch, across to No. 4 on switch M, from this point to No. 4 on the starting switch, through the auxiliary motor, and on to the other phase. The auxiliary motor now runs and drives the rotor switch, cam X, and cams W_1, W_2, W_3.

This closes stator switch and No. 4 wire by cam W_2, No. 1 is then opened by cam W_1, the auxiliary motor continues to run through No. 4 wire contact until all resistance is cut out of rotor circuit, when cam W_2 opens contact No. 4 and puts in contact No. 3. This operation stops the auxiliary motor until the pump raises the accumulator sufficiently high to change over the operating switch to the off position, thus putting the auxiliary motor again into circuit, and revolving the rotor switch to the off position, and opens the stator switch by cam X. On switch M is a contact No. 3, which is used, in case of failure of supply, to prevent damage when supply is resumed. When supply fails, switch M opens, putting contacts 3 and 4 in connection with each other; thus, when the power is again put on, current can pass to the auxiliary motor by way of cam W_3, through 3 and 4 on switch M to auxiliary motor, revolving automatic switch to the off position immediately, and preventing switch M being closed with all resistance out.

Between arms B_1 and B_2 is coupled an automatic magnetic blow-out coil, which is opened and closed in conjunction with the automatic switch to prevent sparking on the rotor switch.

DISCUSSION.

The President (Col. R. E. B. Crompton) invited Mr. W. M. Mordey to open the discussion, but, as he did not respond,

Mr. ROGER T. SMITH (Great Western Railway) was called upon. He said that both Papers were interesting, not only to electrical engineers, but to railway men generally, as showing the amount of electrical working of railway apparatus that was being carried out by one very progressive railway. He would first like to draw attention to the lifting speeds of the various cranes referred to in Mr. Henderson's Paper. The under-hung jib crane at the New Bridge Street warehouse hoisted at 150 ft. per minute, and the height of the hook above the rail was about 20 ft., so that it could not lift a load for more than about 12 ft. This meant that at the above speed one ton was lifted in rather less than five seconds; as the average load would be a quarter of a ton, it appeared to him to be very much too fast, and that the motor would always be running on its resistance and would never get on to its own proper curve. He thought the speed should not exceed 50 ft. per minute instead of 150 ft., and in that case the motor would be reduced from 15 h.p. to 6 h.p. The travelling hoists at the same warehouse, working at the rate of 150 ft. per minute, lifted one ton in about 28 seconds. This appeared to him too slow, and it would be a great advantage if the speed had been 200 or 250 ft. per minute. The jiggers at New Bridge Street lifted 70 ft. at the rate of 100 ft. per minute; this meant that three-quarters of a ton was lifted in about 40 or 42 seconds. This speed might very well have been 200 ft. per minute, and he would like to ask the author whether, in the event of this apparatus being redesigned, these speeds would not be altered. The travelling and traversing speeds appeared to him to be very good. The under-hung jib travelling type of crane, described in the Paper, and the travelling hoists were a most excellent arrangement, and on reading the Paper he went to Newcastle to see these cranes, and they were going to be adopted on the Great Western Railway in consequence. Another very excellent arrangement was the interlocking of the jigger lifts at this warehouse, and he quite agreed with the author that this was entirely satisfactory. Referring next to the design of the electric capstans, he stated that these pulled one ton at 250 ft. per minute, and, allowing about 85 per cent. efficiency of the gear, the brake horse-power would be about 20. In the Paper the actual rated brake horse-

Digitized by Google

power of the motors was stated to be about 26, and he would like to ask the author if the reason for having such a much larger rated capacity than seemed necessary was not due to the fact that the motor was not a compound motor. The author had given some very interesting particulars as to his ideal of a capstan, and with most of these he agreed. But he would go a little further, and should say in the first place that, as sweating within the capstan case was absolutely inevitable, they should do away with all fine wire coils and have only a series motor. Secondly, he quite agreed that the treadle should only close the main switch by a spring or counterweight, and the apparatus shown by the author seemed to be admirable in every respect. There must be some sort of resistance in series with the motor, however, and this, in his opinion, should be cut out independently, either mechanically or electrically, preferably electrically. Then a brake was necessary to prevent the series motor running away when it was running light, and that might be put on either electrically or mechanically; preferably mechanically, possibly such an apparatus as the centrifugal form of brake described by Mr. Taylor. Further, the capstan head should be driven direct by worm gearing, the worm being cut at such a low angle, less than 10°, that the capstan head can at once pull itself up. If possible, the overload circuit breakers should be outside the box altogether, so that they could be reset easily by hand independently of the box. If, as in many cases in railway work, the cables were overhead, the circuit breakers could easily be placed upon the posts. Again, he would have an electric heater inside every capstan box, with proper ventilation holes, and lag the whole of the inside so as to prevent sweating as far as possible. Mr. Henderson had described in a very few words a most interesting runway in the Forth Bridge warehouse which serpentined in and out. He had been up to see this piece of apparatus, and was convinced that travelling cranes of the sort described, and this sort of runway for dealing with goods in goods stations, were going to oust jib cranes altogether. He could not, however, congratulate the author upon the electrical arrangements of that runway. The whole of the lattice-work was alive, and the arrangement was very similar to that in which in carrying a tramway across the bridge, the whole of the bridge was electrified and the electricity collected from the top booms. He did not think that this was necessary or advisable. The very magnificent wagon hoist described was most ingenious, and was a very fine piece of apparatus, but would it not have been far simpler and cheaper to have had a conveyor from the top level to the bottom, and put the goods on the conveyor and run them into the warehouse instead of going to the expense of lifting and emptying the whole of the wagon weight? Turning to Mr. Taylor's Paper, he thought the example of the coal conveyor at the Tyne Dock was a striking tribute to the economy of conveying as opposed to jib cranes. In the words of the Paper, 500 tons per hour required the continuous use of a 16 b.h.p. motor running at an average output of 12 b.h.p.; *i.e.*, 500 ton per hour for 16 b.h.p. installed. In Mr. Taylor's description of the hoisting, lifting, and tipping cranes, 230 tons per hour could be lifted and tipped, requiring the intermittent use of 120 b.h.p. in two motors, about ten times as much for about half the amount of coal delivered. He had worked out the brake horse-power required in two of the most modern tips in the Alexandra Dock in South Wales using hydraulic power, and they required 50 pump horse-power in the tipping-rooms and 100 i.h.p. in the pumping station. The Paper pointed out a very great economy in capital cost in structures and working costs, and he was quite sure that, before long, conveyors for shipping coal into vessels would be used to a very large extent. The enormous maximum power required for cranes was a very important point, if they had a generating station of their own at a dock, for the load factor of cranes was so extremely bad. At the Fishguard Harbour during the past year the annual load factor for both lighting and power, calculated from the amount of work done compared to the working of the plant installed at full load, but exclusive of spares, came out at 9 per cent., and the annual load factor for eleven cranes was 5·3 per cent. A conveyor would probably have an annual load factor of 30 per cent. Mr. Smith then asked of what material the belting used in the conveyor was made? It looked from the illustration as if it were a series of plates, but the speed, namely, 100 ft. per minute seemed rather fast for plates. In the anti-coal breaking arrangement was there any trouble with the centrifugal brake which controlled the speed? Finally, he referred to the three-phase pumps just touched upon by the author. He had happened to be in the makers' works when they were being tested before delivery, and he had noticed that they were centrifugal pumps with a single impeller, but with a special arrangement by which eddy currents in the water were prevented. The instantaneous efficiency of these pumps came out at 80 per cent.: he did not mean to say that they would give this efficiency working steadily, but he believed that this was the highest efficiency ever obtained for a single impeller pump not being a turbine pump.

Mr. C. W. Neele (Great Central Railway Co.), referring to Mr. Taylor's Paper, asked if there were any switches or circuit breakers in connection with the jib cranes to prevent over-winding. The Great Central Railway Co. had installed several electric cranes, but they found a very great difficulty in the small amount of head room available. For instance, if Fig. 4 was to scale, the clearance between the jib and the rail level was about 12 ft. or 13 ft., the ordinary height of a wagon was 7 ft. from rail level to the tip of the wagon side, and allowing 2 ft. for the weight and the hook, this only left 3 ft. or 4 ft. independent of any chain slings. He had installed cranes at the Liverpool warehouses, having a clearance of 18 ft., and had provided safety switches, but these had to be done away with because they could not get the load over the side of the wagon. In consequence, they were continually getting broken ropes, and the crane boys in endeavouring to get the load on to the wagons used the jib of the crane as a lever and tried to drag the load over the top of the wagon. In consequence, teeth were broken in the slewing gear, and the shaft of the slewing pinion was sheared right off. The goods department of the Great Central Railway was working with speeds of over 100 ft. on short lifts, and, with a view to minimising any danger from overwinding, he had been specifying, in connection with some of the cranes they were about to instal, taper winding barrels, so that the load could be lifted at the maximum speed at the commencement, and gradually decreased to its minimum at the top. What was very badly wanted was a more sensitive controller. Liquid controllers met the difficulty to some extent, but they were not altogether satisfactory, and he considered there was room for a really sensitive controller which would be more akin to the control of hydraulic lifts.

Mr. C. F. H. Bayley (South Eastern and Chatham Railway Co.) referred to the awkward design usually associated with capstans; there was so very little room in them for repairs, and the wires, switches, and controllers seemed to be so fragile that with continued damp the insulation broke down. Another criticism was the difficulty of keeping a foot on the pedal with a strong spring acting against it, and at the same time handling a rope. It was necessary to keep a certain weight upon the rope to make the drum bite, and it was very awkward to keep a foot on the pedal at the same time. It was a mistake to work the capstans at too high speeds. His company had a capstan working at 250 ft. per minute, but had found it impossible to draw the rope from the barrel at such a high speed. With such a speed it was found necessary to have one man standing at the pedal whilst another man walked away with the end of the rope.

Mr. Henderson, in reply, said he quite agreed with all the speakers about the speed of cranes; it was undoubtedly a very great mistake to make them too high. Apparently, traffic people on the different railways thought that by having a high speed they probably saved a certain amount of time. But when a complete set of operations connected with a crane was considered, lifting, lowering, slewing, &c., the amount of time occupied in lifting, even at a very slow speed, such as 40 ft. or 50 ft. per minute, was very small compared to the total time taken to handle goods. The apparatus which he had described was designed five or six years ago. His cranes were provided with over-running switches, which were gradually run out with a little worm on the end of the shaft, so that when the load was at the top the switch knocked out. The action of the switch, however, depended upon the amount of the load. If it was a light load it would not knock out in time, and if it was a heavy load it knocked out too soon, due to the momentum of the crane barrel. His own experience was that it was best to get a good man to drive the crane and dispense with such a device. With regard to capstans, here again the speed was very high, but a very large percentage must be allowed for slip in the rope, viz., the head slipping inside the rope which, of course, ran away with a good deal of the power. Electric capstans were notorious for wearing out ropes; this was always a fault of high speed. If it were possible to reduce the speed, far better work would be done. It would certainly be the best plan to mount all switches outside in a sort of box, even if the cables were underground. He did not see why the switchgear should not be put in a small pillar box, which would not cost much extra money; in fact, it would very soon save itself. All the trouble which the North Eastern Railway Co. had had with capstans was due to the gear being inside. They had 200 in use at different places, and the trouble had always been caused by dampness inside. Heaters had been tried in one or two places, but they were too expensive, and had been taken out. They had also tried keeping the shunt circuit of the motors alive, but this again was found to cause trouble occasionally. At West Hartlepool it was responsible for the generators breaking down on several occasions. Weak points in the dynamo armature were broken down when the station single-pole cut-outs went, owing to the inductive rise in these field circuits. He could not agree that hoisting at New Bridge Street would have been better if conveyors had been used. It would have meant a great deal of handling, especially for the type of goods being used, viz., potatoes, which came from Scotland in wagon-loads, and the only satisfactory way was to drop them wholesale into the cellars and unload the wagons afterwards. The only other way would have been to make a slip and run the wagons down with a capstan or hoist at the top. Referring again to the awkward design of capstans, Mr. Henderson said that those at New Bridge Street had a very heavy lid, and it meant a very

Digitized by Google

heavy item in handling them. The method in which the resistances were connected upon some of these capstans was another source of trouble. In fact, with the added cost of maintenance, it was sometimes hardly worth while putting in electric capstans, whereas a little careful thought on the part of those who designed and made them would make things so easy that electric capstans could be made a very great boon. Dealing with Mr. Smith's question as to compound motors, he thought these ought to be the best for capstan working; they really would be better than series motors, because they did away with the necessity for any special machinery such as the friction brake described in Mr. Taylor's Paper.

Mr. TAYLOR, in reply, said the belt of the conveyor described in his Paper was composed of plates 4 in. or 5 in. broad, but the conveyors which were now being installed had a belt composed of a mixture of canvas and rubber. With iron plates, of course, it was possible to use the conveyor as an ordinary spout for gravitation, which was impossible with rubber. So far as he was aware, the centrifugal governor on the anticoal breaker had given every satisfaction.

DISCUSSION OF MR. TAYLOR'S PAPER IN NEWCASTLE.*

Mr. C. FARADAY PROCTOR, referring to the cranes in which the lifting barrel is not keyed directly on to the shaft, asked whether the method of allowing a free run out under the control of the foot-brake only was not apt to induce too great speeds of drop, and consequently very heavy strains on the crane when the brake was suddenly applied.

Mr. CLUTWORTHY asked whether the curious fact that the inclined coal conveyors showed a consumption of practically the same horse-power at any inclination was not explainable by the shape of buckets used, or, alternatively, whether it was not a question of the bulk of the power being used in overcoming mechanical friction.

Mr. TAYLOR, interposing in reply, said that the conveyors were not on the bucket system, but were either canvas belts or a series of iron plates. The buckets were only used in the anticoal breaker. Moreover, the horse-power absorbed in running light was only 1·5 to 2 h.p. The explanation was rather that the belts automatically regulated the amount of coal borne by them according to the angle at which they were placed.

Mr. SLEIGH noted that, in the test of the coal conveyors, the height through which the coal was lifted had not been recorded, and the necessary data were therefore not given to determine the efficiency of the gear. He would like to know whether the figure of 0·017 unit per ton was high or low for the work done.

Mr. LAW drew attention to the fact that, whereas the installation under consideration was driven by three-phase motors, continuous-current motors would be considerably more flexible in working, and he would like further particulars of how the motors were controlled in this instance. In a scheme considered for the Dublin Docks, the question of supply from a power company was settled by the fact that the company's mains were only on the other side of the river, and were not brought across. Therefore, a generating station for the particular work was put in, and 500-volt continuous current was used. Having regard to the special conditions existing in this case—alternate current supply being available, and direct current only obtainable through motor generators—he would like to know whether the question of using alternate-current commutating motors had been considered.

Mr. FARADAY PROCTOR drew attention to the fact that in the older days it was considered unsafe to attach a rope direct to the turning head of a capstan, as any accidental starting of the gear might involve very serious results in pulling the load about when it should not be moved. For this reason it had become standard practice to throw two turns of the rope round the bollard and then start the movement by pulling on the loose end.

Mr. BROOKING referred to the question of the plugs used for taking current from the underground mains on the quay for the cranes. When a plug-box is level with the surface of the quay it usually gets full of dirt and water, due to the cover not always being replaced after use of the plug. This leads to short circuits and general unpleasantness. Had Mr. Taylor any special arrangements to avoid this? In his opinion a device, such as a feeder pillar, should be employed, so that water could not get in unless put there by a fire-hose. Five or six years ago there were more cranes of this type stopped by trouble in the plug-boxes than by breakdowns on the motors.

Mr. CARRICK said that supply of power from a steam station at Tyne Dock had been rather discountenanced in the Paper. At the same time, there were such things as failure of electricity supply, and this had occurred. Supposing such a failure took place at night, and dock-gates are not closed, if steam is not available to get them closed some of the ships in the dock would be on their sides in the morning. Another point was that the motors driving pumps at Tyne Dock start at full speed and remain at constant speed. Variable speed would prevent the accumulators coming down so frequently.

Mr. J. ANDERSON asked if any trouble had occurred with the use of friction clutches in capstans and the like. He would also like to know if the auxiliary motor of the hydraulic pumping plant automatic starter was of the same voltage as the main motor. In his opinion a standard controller operated hydraulically would be better from the point of view of simplicity and sureness. An objection might be that of possible freezing of the water in winter, but in plant of this type, under his own observation, no trouble from this cause had been experienced for four years. He would have thought, unless the fluctuations of the load were very great, that automatic control of two pumps would have been sufficient. It was possible to use ordinary squirrel-cage motors and bye-pass the water, the running losses being very small; £150 per motor or more could be saved in starting gear by this method.

Mr. F. O. HUNT wished to know, with reference to the inclined conveyor, what happened if it were worked on a downward incline. Would it be used just as a shute or as a brake on the coal going too quickly?

Mr. TAYLOR, replying to the last speaker, said that the lifting and tipping barrels are geared together, so that they revolve at the same speed. Mr. Proctor feared that lowering too quickly would throw an excessive strain on the crane on pulling up. No ill-effect from this cause had been experienced, and no special precautions had been taken except the ordinary dashpots and the factor of safety of the crane. In reply to Mr. Sleigh, the vertical height through which the coal was lifted on test was about 11 ft. Mr. Law had raised the point regarding the types of motors in use. As a matter of fact, the crane motors were direct current. The motors adopted for driving the pumping plant were three-phase, because a definite speed must be maintained. Also, they were used on the coal conveyors as a uniform speed was necessary. He agreed with Mr. Brooking that trouble is experienced with surface boxes, unless they are very good. Difficulties in connection with this had, however, now been got over.

* The Newcastle discussion on Mr. Henderson's Paper has already been reported (ELECTRICAL ENGINEERING, Jan. 16, 1908).

LONDON TRAFFIC AND RAILWAY ELECTRIFICATION

A PAPER with the above title was read at a meeting of members of the Royal Automobile Club on Thursday, February 6th, by Mr. Philip Dawson. In the first portion of the Paper he mentioned some of the early landmarks in the history of railway electrification, and pointed out how the three principal causes which in the past have produced electrification had been :—

(1) Difficulties of ventilation, such as exist in the case of tube railways, ordinary underground lines such as the Paris Metropolitan, the Budapest, and the Berlin Underground, the Orleans line in Paris, the Mersey tunnel, and the Metropolitan District Railways; or such as exist on Alpine routes like the Simplon Tunnel.

(2) The costliness of fuel, and the abundance and cheapness of water power. This was principally responsible for such electrification as the Valtellina, the Burgdorf-Thun, and the Milan-Varese lines, as well as the Swedish State Railways.

(3) The desire to increase the earning capacity of existing lines, and station facilities, and to handle more rapidly and more effectively heavy suburban traffics. This is responsible for the very large scale on which electric traction has been introduced on the New York Central and on the New York, New Haven, and Hartford lines, and for its adoption on the Hamburg-Blankenese line, on the Lancashire and Yorkshire and North-Eastern, and for the decision of the London, Brighton and South Coast Railway to adopt it provisionally on their South London line with a view of confirming its technical merits before finally adopting it for the whole of their suburban system. Shortly after this work was put in hand, the Prussian Government decided, for reasons similar to those which weighed with the British Company, to electrify the whole of the very large suburban system in and around Berlin, involving some 200 miles of lines and an expenditure of £2,000,000.

As far as this country is concerned, he continued, the only railway electrification which need be seriously considered is that of suburban lines which will have to be operated electrically in order to enable a better utilisation of existing traffic facilities and with a view to meeting tramway competition.

Mr. Dawson then reviewed at some length the advantages which electrical working presents over steam, and said :—

Generally speaking, some of the principal reasons which may be expected to eventually cause a saving in cost when electric

Digitized by Google

is substituted for steam haulage on a large scale may be summarised as follows:—(*a*) Fewer electric motor trains or electric locomotives are required than steam trains for a given service, in consequence of higher rates of acceleration and of less time required for repairs and maintenance. (*b*) The reduction in fuel consumption and also in the quality, as well as in the cost of the fuel required. (*c*) The fact that, with the same number of tracks and terminal platforms, a much better service can be given with electricity than with steam.

In dealing with the question of cost and general results of electric traction, reference must be made to the District Railway, which is often held up, and constantly being quoted as an argument against electrification. In this connection it is only fair to point out that the conditions which obtain there are totally different from those which exist in connection with the operation of suburban trains on our big railways. The District is principally suited for short distance traffic, and, therefore, motor omnibuses and tramway competition cannot be combated with success. What would have happened to the District, as regards decrease of traffic, had steam been retained, it is difficult to foresee. Furthermore, the location of a great portion of the line, as, for instance, under the Embankment, is far from ideal from a traffic point of view. Electrification was not carried out in an ideal manner, a considerable amount of the rolling stock is unsatisfactory, both in design and construction, and troubles have been experienced with side doors, axles, and bogies. The services have not always been materially improved as regards frequency above what existed in the time of steam trains.

In considering the District, it is only fair to remember that the rolling stock operated by steam was of the lightest possible description, and of such a nature as would not be tolerated by the passengers accustomed to main line rolling stock, and, furthermore, that, during the many years before electrification took place, undoubtedly very insufficient allowances were made for renewals, not to speak of depreciation. There is also this great difference between the case of the District and the one under consideration, that the electrification of the District involved a scrapping of the whole of the rolling stock, locomotives, and practically the whole plant and equipment used in connection with steam traction; whereas, in the case of the electrification of a suburban railway, this would go gradually, and the rolling stock and locomotive plant superseded would not be scrapped, but would be used on other portions of the line, and would therefore not have to be written off.

The electrification of the District cannot have been carried out on the best conditions, and it is fortunate that there are figures available of a very similar line, the Mersey Railway, where electric traction entirely replaced steam in the course of one day. These figures show that for an increase of 10 per cent. in the total expenditure the train miles have been increased 167 per cent., whilst locomotive expenses for 1901, when worked by steam, were 13·65d. per train mile, and the expenses for the same items, when worked electrically in 1906, were 5·95d. per train mile. The apparent saving is not as great as appears at first sight, as the electric trains on an average are smaller, having a seating capacity on the average of half of that of the steam trains.

Having thus discussed the problem of electric traction in general, he briefly referred to the various systems of electric traction now in use, pointing out, amongst other things, that the three-phase system was in general only economically satisfactory for long distance work. The limitations of voltage and the consequent unwieldy conductors in continuous current working were also alluded to, and finally particular attention was called to the more recently developed single-phase system adopted by the London, Brighton and South Coast Railway, and decided upon by the Midland for their Lancaster and Heysham experiment. This system has also been chosen for the electrification of the Prussian State Railways in and around Berlin.

In the case of the Brighton railway, a pressure of 6,700 volts has been adopted on the overhead working conductor, although the insulation used is of such a nature and design as to enable 10,000 volts being used at a later period, should this be found advisable. These currents are led from the overhead conductor to the transformer situated underneath the car, in which the currents are transformed to a pressure of about 300 volts, and this is the only pressure accessible either in the motors or any of the conductors running along the coaches, and, therefore, none of the employés of the company are subject to any danger from shocks.

The author briefly summarised the position as regards railway electrification as it appeared to him as follows:—

(1) Electrification of the suburban portions of railways dealing with heavy local traffic appears to be essential, both in order to meet the very serious tramway competition, as well as better to utilise existing track and terminal facilities, and in order to save the enormous capital expenditure which an enlargement of the number of tracks and terminal facilities would involve—when, indeed, this is possible.

(2) As regards the system to be adopted, it should be such as to easily lend itself to extensions, even to considerable distances, and so as to interfere as little as possible with existing structures and permanent way, and to cause no fresh source of danger and annoyance to railway employés.

(3) It is useless to expect satisfactory financial results except when electrification is adopted on such a scale as to make it possible to fully reap its benefits, and unless it is so installed and operated as not to be constantly interfered with by existing local steam trains sandwiched in between the electrical ones.

(4) It is no use adopting electric traction if rolling stock of such a nature and design is adopted as will neutralise the benefits resulting from electric traction at termini.

(5) Economies in working may, and will, no doubt result, if and when the system has been sufficiently developed, but if electrification is only resorted to in order to decrease working expenses, and not in order to increase the earning capacity, then nothing but disappointment must be expected.

(6) It is no use electrifying unless frequent as well as rapid service is given.

DISCUSSION.

(*Abstracted from the "Royal Automobile Club Journal."*)

After a few words from the Chairman (Mr E. MANVILLE), The EARL OF BESSBOROUGH, C.V.O., C.B. (Chairman of the London, Brighton, and South Coast Railway) opened the discussion with some appreciative remarks, and was followed by—

Mr. FORBES (General Manager, London, Brighton, and South Coast Railway), who said that he must claim, like his Chairman, to have only a small technical knowledge of the subject. When Mr. Dawson approached the London, Brighton, and South Coast Railway Co. with the electrification proposal, he (the speaker) was impressed by the advantage to be gained at the terminals. They had spent at Victoria Station about one and a half millions, in order to be able to bring a greater number of trains into the station. To tackle the same problem at London Bridge would mean four or five millions, an expenditure that was, of course, out of the question. The time taken in getting trains into and out of that station was on an average 7 or 8 minutes per train, but for an electrical train only from 2 to 2½ minutes were required. There would thus be a gain of something like 5 minutes per train in the terminal accommodation. If the new system did not enable them to do anything else, he hoped that it would, at any rate, enable them to put on additional trains for their longer-distance passengers.

Lord RIBBLESDALE spoke of the influence of electrification upon overcrowding.

Col. Sir HERBERT JEKYLL, K.C.M.G., R.E., referred to the work of the Traffic Commission, and emphasised the importance of that co-ordination of tramways and railways that Lord Ribblesdale had recommended. It did not look as though railway companies would be able to widen their lines very much near London, as the cost was prohibitive, and the only way of increasing their capacity was, as Mr. Dawson suggested, to make the existing lines carry more traffic.

Mr. W. WORBY BEAUMONT said that with regard to some of the railways in England, it was to be remembered that, although the increase in the number of trains rendered possible by the substitution of electric for steam locomotives, would secure a very considerable return to those railways, there was another question—the accessibility of the railway stations to the public.

Mr. W. R. COOPER hoped that people would not regard electric traction as capable of regaining lost local traffic, whatever the conditions. For distances of a mile or two, electric railways could not expect to compete successfully against tramways or motor omnibuses along parallel routes. It was for longer distances that, he thought, electrification was advantageous.

Mr. OLIVER BURY (General Manager of the Great Northern Railway Co.) said that the problem was a commercial one. There were many railways round London with a longer distance traffic in which they had been able to cloak their suburban traffic, and it was not always known whether that suburban traffic paid or not. On the Great Northern they had been at great trouble to find out whether their suburban traffic paid or not, and they had recently had electric tram competition in their district. Those trams had taken quite a million of their passengers in the last six months, but such passengers were those who travelled between two or three suburban stations, and perhaps lived in the road through which the trams passed. The company still had to run those trains, and they missed those passengers. No amount of electrification was going

Digitized by Google

to get them back again. Some time ago he asked for tenders for the electrification of the whole of their suburban lines. The company gave every sort of information to the gentlemen sending in those tenders, but the gentlemen in question told the company that it must not expect to carry the passengers any cheaper. He agreed that they might get trains in and out of a terminal station a little quicker, but not much quicker. He was prepared to admit that by electricity the trains could be accelerated, but, as one of the greatest firms in this connection told them, they could run more trains for the company, but even then the company could not carry more passengers. He did not see in those circumstances how a case could be made out for a board of commercial gentlemen who wanted to see a successful result. Sir Herbert Jekyll had said that they must cultivate their traffic a little further out. The Great Northern did that, and they did it with steam just as well as with electricity. If the nearer suburban traffic did not pay, why should they put 1½ millions sterling into electrifying it? He had had the biggest firms come to him, but they could not make out their case. Where was the advantage in carrying people if it did not pay? They could not get at the actual facts as to the results after electrification, either from the States or anywhere else.

Mr. A. C. ELLIS (General Manager, Metropolitan Railway) said that his line had been steam, but now was electric. They had in this way obtained experience, but they had had a bad time of it. That was due to electrifying a steam railway, which was quite a different thing from starting quite fresh; the conditions were not at all comparable. Coming first of all to the commercial question, they were less comparable still. In their case they were running a steam railway, and fairly successfully, paying as much as 3 and 3½ per cent. They had to electrify whether they liked it or not. The facts were that they had gone down from that percentage to a half per cent., but that was not due entirely to electrification. When they were running their concern by steam they had the plant and everything going, and it earned the money. Then when they came to electrify, they had an entirely different plant, and they had to pay for it. When they came to put aside and realise the old plant they could get very little for it; it had to be practically scrapped. Capital had to be raised by preference stocks, and that largely accounted for the drop in interest on the ordinary stock. Then, after the arbitration, they had to adopt a system they did not want to adopt. He (the speaker) agreed that the arbitrator took the only course he could take, having regard to the time at which the question was brought forward. The subject of electric traction had moved on since then. They had to adopt the direct-current system with a positive rail and also an insulated negative rail, and so were using the most expensive system of railway traction in existence. If they had been able to use either the three-phase or the single-phase system, their capital might have been perhaps a half less, and their maintenance expenses a third less. At least, so they were advised. But they had to have electric traction then and could not wait. The contractors paid the expenses of that inquiry, and they failed, he thought, because electrical traction other than the direct-current system was then only in the experimental stage. Mr. Bury had severely criticised electric traction. Mr. Bury's suburban traffic was not the suburban traffic of the Metropolitan or of the District or of the Tube Railways, and although Mr. Bury said that he could work very quickly at the terminals, yet he (the speaker) thought that, if he came to Baker Street, he would find there that they did it as quickly as any company could do it, and with no very marked difference between the time taken, even when using an electric locomotive. They found that where they could bring a train in and out in from 2 to 2½ minutes, they could do it now in from 1 to 1½ minutes in a busy time, with the passengers getting out on one side and in on the other. Then there was the question of rolling stock. They had the corridor trains with the gates. There must be more control over each train when they were running electrically, if they were going to have an acceleration of 1·5 ft. per sec. per sec., which was about as much as the passengers could stand. The system had many advantages, but it also had its disadvantages. On the Tube railways they had gates at the end, but the Metropolitan found that on running into the country there was such a tremendous draught that they had to have a closed vestibule. Over here people did not like standing in gangways, and there were certain public departments which did not think it was proper. Then the company had to consider the complaints of people coming from 14 or 15 miles out, and so they thought that they might use some of the old stock, and accordingly converted their ordinary rolling stock of the type always used in England, put motors on, and ran block trains. Those trains ran very well, and were much appreciated by the public. The travellers had suited themselves to the circumstances, got in and out quickly, and did not try to get into the train after it had started. The Metropolitan had been the victims of experiments, but they had got over that, thanks to the very excellent staff. Mr. Dawson had stated some running times taken by steam and by electricity, and he would like to tell them that on the Inner Circle Railway of 13 miles they had 27 stops, and they took 70 minutes to do it formerly; they could now do those 13 miles, with 27 stops of 20 seconds each, in 50 minutes. That brought him to the fact that those trains started quicker, and that they would brake quicker, which meant a greater wearing on the tyres and on the rails. In England one did not see a broken rail; at any rate, they were very rare. Abroad the percentage was very much higher. That was due very largely to the composition of the steel in the rails. The engineers were afraid to make the steel of the rails too hard, but they were now making it harder. The Metropolitan had hardened the check rail, and thereby practically solved the problem of electric trains running over the permanent way. Then they found that they must go in for automatic signals. He would like to go even further, and say, "Light the tunnels and run by sight." He would be willing to reduce the speed and the weight of the trains for that. He knew that their rails had some nasty curves, but these curves could be provided for, and they must get a system of following more quickly. If they came next to the question that Mr. Bury asked as to the cost of running, either per train-mile or per ton-mile, comparing steam with electricity, he would say that the balance would be in favour of steam. He had got out some figures, and after taking out the weights of the steam trains, and taking the electric trains, putting them all evenly, he found there was a difference of something like a penny, but to get that he had to include a certain number of steam trains and goods trains, and compare them with the all-steam trains up to December, 1904. If they eliminated the steam and goods trains at present run, there would only be about five-hundredths of a penny per train-mile in favour of steam as against electricity. It was quite true they gave the passengers more by electricity than they used to get by steam, but they would never get those passengers to travel now if they went back to steam. Mr. Bury had said that they must look at this financially; but, of course, they must also look at the fact that electricity was improving every day. He wondered that, having started three-and-a-half years ago, what they started with was not now out of date. They had come to the conclusion that depreciation was a very serious thing, and had put by a very considerable sum for it. It must also be remembered that when they had steam the "tubes" had not been started, and the other forms of competition were not in existence. It was hardly fair, therefore, to say that the old Metropolitan and the old District were not a success run electrically without considering the other facts that had brought them to their present position. The more one was in the position of a wholesale merchant of electricity, the more one was likely to be financially successful. The Metropolitan was now big enough to consider itself a wholesale merchant, and he believed that they would be able to show better results.

Mr. DAWSON, in his reply, said that he believed that electric traction was going to be one of the few solutions—if not, indeed, the only solution—of the overcrowding problem. They must look forward to people going, not four or five miles out, but 10 or 15 miles away from their work. The solution of the rolling stock question was an easy one; it consisted simply in a slight alteration of the side-door type. It was well known in Europe—particularly in Germany, where those trains were used for suburban traffic. It consisted simply in cutting away a portion of the compartment and converting it into a sort of corridor train. Everybody—railways and tramways and the travelling public—rejoiced to see that the Board of Trade had followed the recommendations of the Commission, of which Lord Ribblesdale was such a shining light, and had appointed Sir Herbert Jekyll to consider the whole question from the broad point of view. Mr. Beaumont also touched upon the question of the accessibility of the stations. He (the speaker) did not think that that was so important as it appeared at first sight. If they were considering distances of only three or four miles, that would be very important, but for distances beyond that it did not matter so much. Trams were running at their highest rate of speed, and with the crowded state of the streets that would not increase, but railways would very materially increase their speed—would, in fact, nearly double it. If those trains were now travelling 10 or 12 miles, there was not much to choose between them and the trams, but if they were going to be able to travel 25 miles an hour, there would be a great advantage in their favour. Mr. Bury apparently did not suffer from traffic difficulties. He (the speaker) agreed that the electrification question was a financial one. If they were not going to increase their receipts, but were going to increase their expenditure, then it would not, of course, be wise to electrify. He thought that Mr. Bury must have got the tenders of experts some years ago, and electricity had travelled very far since then. Mr. Bury was numbered that evening among the doubters; perhaps in a few years' time he might be numbered amongst the faithful. Mr. Bury seemed also to be in an exceptionally happy position, because he could run the same service of 10 or 15 miles at the same speed as by electricity. There were not many lines in that position. Mr. Ellis had confirmed his most sanguine expectations—namely, that, under the most difficult conditions in which he had been placed, he had been able to operate at practically the same cost as with steam. If the Brighton Co. were as successful as that, they would be perfectly satisfied.

ELECTRIC DRIVING AT THE MOTHERWELL IRON AND STEEL WORKS

An Electrically Driven 500 h.p. Rolling Mill

By the courtesy of Mr. J. Frood, General Manager of the Motherwell Iron & Steel Co., Ltd., we were recently permitted to inspect an important application of electric driving at these iron-works. The works contain two steam-driven mills, and a new 15" "merchant" mill has recently been added, in which electric driving is employed. The mill in question is utilised generally for rolling sections and strips, and is driven by a 500 h.p. motor. In addition to this, the hard rolls, live rolls, shears, straightening machine, and other appliances used in connection with the mill are electrically driven.

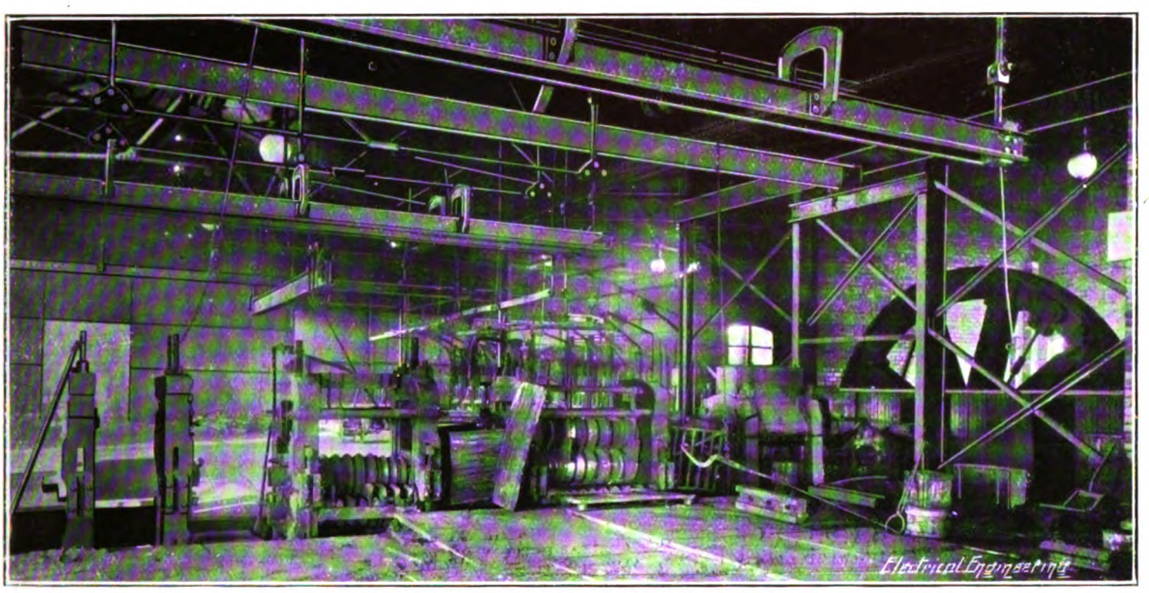

Fig. 1.—General View of Rolling Mill.

Most interest, of course, attaches to the large mill which is worked on the slip regulation system by a 500 h.p. three-phase motor. A general view of the mill is shown in Fig. 1. The motor is shown in Fig. 2. This motor, as already stated, is a three-phase motor rated at 500 h.p., and it runs at 145 to 150 revs. per minute. Between the motor and the mill is a 28-ton flywheel 19 ft. 6 in. in diameter. The frequency is 25 cycles per second, and there are 20 poles. By means of the slip regulator, to which reference will be made presently, the speed can be reduced momentarily to 110 revs. per minute if necessary, to allow the flywheel to give up extra energy to the mill during the short periods of very heavy load. The motor has a bar-wound rotor, and current is supplied to the stator at 2,000 volts. The weight of the rotor, together with its coupling, is 7 tons. Fig. 3 shows the coupling employed to connect the rotor to the flywheel. A flexible packing is employed to relieve the machine, to some extent, from the shock which it will necessarily experience as the work is put into the rolls.

The slip regulator is based on the following system:—The windings of the rotor are connected to a liquid resistance, and this resistance is made to increase automatically as the load on the motor increases. The insertion of resistance in the rotor naturally causes it to lag behind the stator in phase, and, as the speed decreases, the flywheel supplies energy to the system, as already explained. A similar type of slip regulation is used both for the large merchant mill and also for the smaller hard rolls, which are driven by a 125 h.p. motor. A photographic view of the two regulators, showing the smaller one in the foreground, is given in Fig. 4; and Fig. 5 is a drawing showing the regulator more in detail.

The same piece of apparatus includes both the starter and the regulator. The upper part of the vessel contains a number of horizontal pipes, through which water is circulated to keep the liquid cool, and below these are large horizontal plates which can be lowered into the liquid to decrease the resistance between them and fixed electrodes at the bottom of the tank. As the liquid is

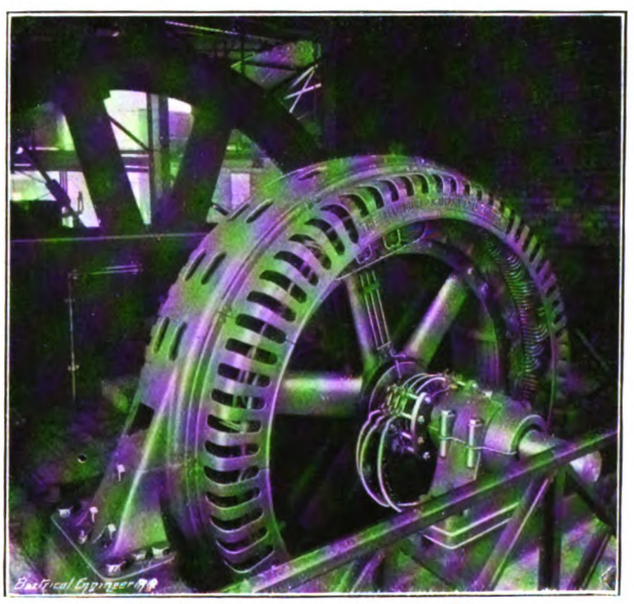

Fig. 2.—500 h.p. Rolling Mill Motor.

heated it rises and is cooled by the cold-water pipes, so that there is a continuous circulation. The moving plates are actuated by a hand wheel, and are also independently attached to lever carried on a projecting spindle by a small brake motor. The other end of this lever carries counter-balance weights.

To start the mill motor, the plates are lowered by

Digitized by Google

means of the hand wheel after the main stator switch has been put on. After they have been lowered a certain distance, the lever engages with the lever attached to the brake motor. In the stator circuit of the rolling-mill motor there is a small three-phase series transformer, the secondary circuits of which are connected to the stator winding of the brake motor; the rotor of the brake motor is an ordinary short-circuited rotor. As the current supplied to the rolling-mill motor increases, the potential across the primary of this series transformer also increases, and the potential of the secondary rises sufficiently high to start the brake motor, the speed of which will, of course, depend on

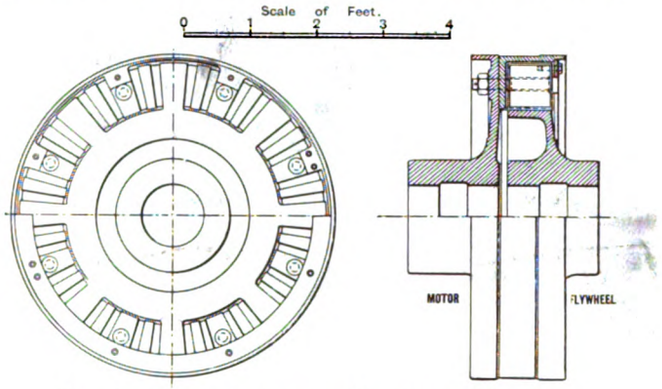

FIG. 3.—COUPLING BETWEEN MOTOR AND FLYWHEEL.

the amount of extra load on the main motor. As the brake motor turns, it lifts the plates which are in the liquid and thus increases the resistance of the rotor carried in the main motor, and the speed of the main motor drops. When the load diminishes again, the brake motor no longer exerts sufficient torque to counter-balance the difference in weight between the moving plates and the counter-weights, and the former again fall, decreasing the resistance of the stator circuit in the main motor, and allowing it to speed up again, thus restoring to the flywheel the energy that it has given up to the mill during the heavy load period.

high-tension board, where the oil switches and 'bus-bars are placed. The three isolating links are manipulated by one handle, and there is a main switch so arranged that the door of the chamber cannot be opened unless the switch is off.

The oil switches at the back of the board are arranged with an overload release in the usual way, and there are no independent circuit-breakers. The board to the

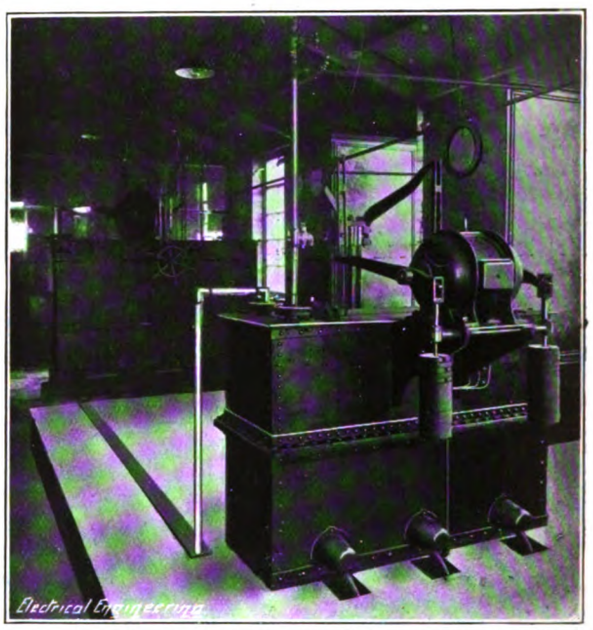

FIG. 4.—SLIP REGULATORS FOR THE 150 AND 500 H.P. ROLLING MILL MOTORS.

left hand of the drawing are used for the large mill motor and the smaller motor on the hard rolls. The right-hand board supplies current at 400 volts three-phase for the other motors employed. It should be mentioned that the two slip regulators are shown more or less diagrammatically on this drawing, and that the

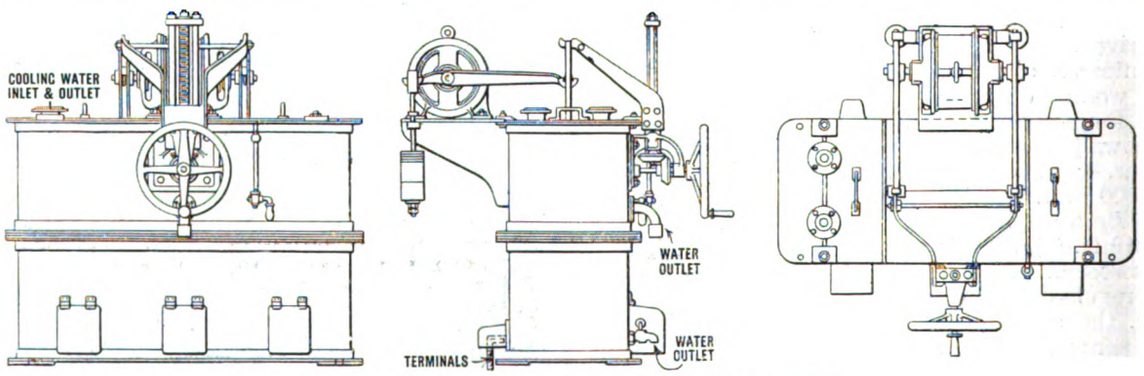

FIG. 5.—GENERAL ARRANGEMENT OF SLIP REGULATOR.

The mill has only been in operation for a short time, so that it is difficult to give any figures as to the consumption of electricity; but, roughly speaking, 40 Board of Trade units are used per ton of iron rolled.

Current is supplied by the Clyde Valley Electrical Power Co., Ltd. 11,000-volt overhead E.H.T. mains are taken from the company's North Motherwell sub-station, and the current is transformed down to 2,000 volts in a small sub-station which the Clyde Valley Company have erected close to the mill, and thence the mains go underground to the switch-room in the basement beneath the slip regulators, entering through the cable duct seen in the cross-section of Fig. 6, which shows the general arrangement of the plant. In the chamber just above this are the isolating links, and a narrow passage is left between these and the back of the

one used for the smaller rolls is of a considerably smaller size than that used for the 500 h.p. motor. In the case of these smaller rolls, the motor is also connected directly to them, and the whole system is exactly similar to that in use with the large merchant mill, but on a smaller scale.

The live rolls on which the material travels as it passes out of the mill are driven by a 20 h.p. 400-volt three-phase motor running at 750 revs. per minute, through a spur gearing with about 10 to 1 reduction. A connecting rod attached to the last wheel of the train drives the rollers themselves. The motor is beneath the floor, but is readily accessible for inspection and repairs by lifting a plate. Its speed is regulated as usual by resistance in the motor circuit, and the arrangement is such that some resistance is always left in circuit.

seen in the illustration. The main switches and ammeter are contained in a watertight case, and there is

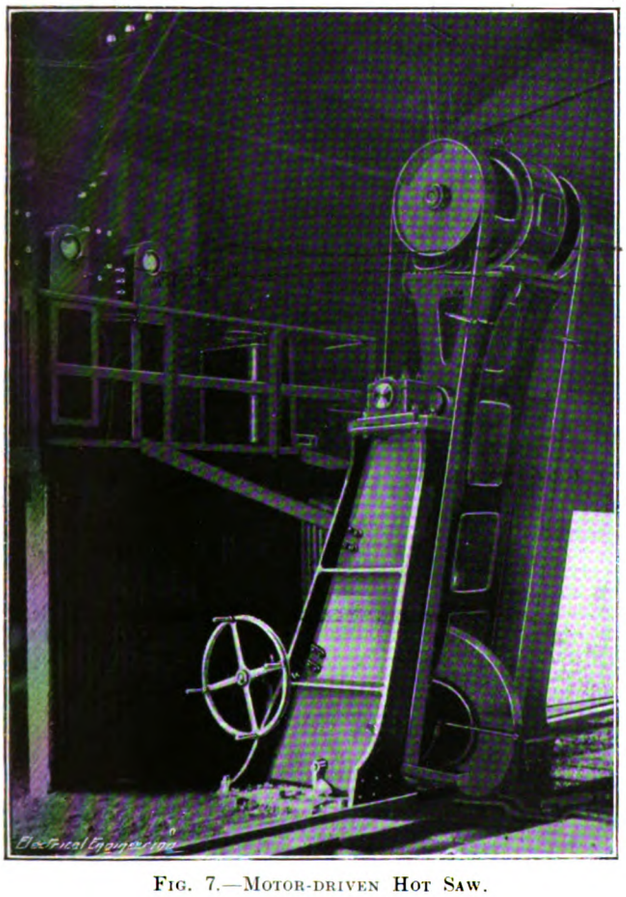

Fig. 7.—Motor-driven Hot Saw.

a controller on the front of the platform that puts resistance into the rotor circuit.

The shears shown in Fig. 8 are driven by a 20 h.p. motor running at 720 revs. per minute. At the top is a flywheel, which is driven from the motor through single reduction gear; and a triple reduction gear, independent of this, drives the shears. In addition to the starting switch and the resistance switch in the rotor circuits, there is a short-circuiting device on the motor itself, as there may be to some extent a variable resistance between the brushes and the slip-rings owing to

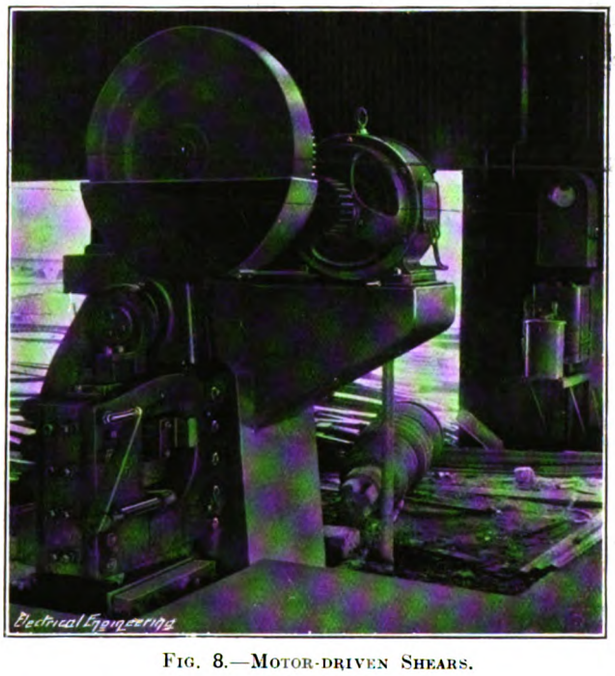

Fig. 8.—Motor-driven Shears.

the jarring of the machine. The motor is not mounted on springs, as is done in some works to prevent it from receiving mechanical shocks, but a raw hide pinion is used.

Two other motors, rated at 30 h.p. and 20 h.p. respectively, drive a reeling machine and straightening machine. The latter is used for polishing bars and taking the scale off them. Both these motors are fitted

Digitized by Google

with the same short-circuiting device as is used on the shears motor.

All these motors are connected on separate circuits on the 400-volt board in the basement, and the fuses, switches, and ammeter near the machines are in each case enclosed in the waterproof iron case already referred to in connection with the hot saw. This case is again clearly seen in our illustration of the shears.

The arrangements for driving the two mills, and also the other motors, have been installed by the Electrical Company, and their Glasgow representative kindly accompanied us to the works, supplied us with much of the data included in this article, and made arrangements for photographs to be taken for us. We have also to thank the Clyde Valley Electrical Power Company for their assistance.

This is not the first introduction of the Motherwell Iron and Steel Company to electrical driving, as many of the machines used in connection with the two steam-driven mills are electrically driven. These take current at 460-volt continuous-current from the Motherwell Burgh Electricity Works network.

THE COST OF ELECTRICAL POWER SUPPLY

MR. J. F. C. SNELL'S Paper on this subject was discussed at Sheffield last week by the Leeds Local Section of the Institution of Electrical Engineers. The Paper and reports of the discussions in London, Glasgow, and Dublin will be found in our issues of January 16th, 23rd, 30th, and February 20th.

Mr. H. E. YERBURY (Sheffield Corporation Tramways Department) opened the discussion by remarking that some of the author's axioms and tables were open to criticism; he did not, however, make any direct attack on them. He agreed that the cost of equipping large power stations could not be reduced to less than £12 or £13 per kilowatt installed. He was sorry to see that in Table VIII. the Sheffield costs had been omitted from the comparison. Their charge for power was 0·6d. per unit, and the works costs 0·36d. Viewing the Paper as a whole, he considered the arguments advanced for centralisation, and the contention that local generating stations should obtain extensions of supply from a power company or by co-operation among neighbouring towns, was more applicable to London than the provinces, where he was sure it would be impracticable.

Mr. WILSON HARTNELL (Leeds) was of the opinion, as the result of considerable experience among manufacturers, that where existing factories are already supplied with efficient power plant, they could generate electrical energy for themselves more cheaply than it could be obtained from outside sources. At the same time owners would prefer to avail themselves of an outside power supply, even at an enhanced price, to sinking a large amount of capital in extra plant. They would be prepared to pay up to 1d. per unit, although they might generate for themselves at, say, 0·6d.

Mr. S. E. FEDDEN (Engineer and Manager, Sheffield Corporation Electricity Supply Department) considered the author's tables fairly accurate, although they were not quite to his way of thinking. In many of the Sheffield works the load factors are of the following order:—300 h.p. load factor 18 per cent., 600 h.p. 14 per cent., 1,000 h.p. 7 per cent. These works could not put down their own plant with the necessary spares and supply themselves at as low a rate as they could obtain current from the Corporation. The running load factor in the Sheffield generating station is from 40 per cent. to 45 per cent.* Referring to Table I., he pointed out that the price of town's gas is taken at 2*s.* per 1,000 cubic feet, but in Sheffield it can be obtained for half that amount, and yet his department are adding to their power demand at the rate of 200 to 300 kilowatts per week. The examples of suction and producer gas plants in the Paper must, he thought, have been very perfect producers, engines, and men. After taking into consideration the expenses incurred by shutting down for cleaning and repairs, wages of attendants, explosions, &c., many users of such plants in Sheffield had changed over to the Corporation supply. The speaker doubted if a power company could supply in Sheffield as cheaply as the Corporation, because their diversity factor would be very small for several years. The average price obtained by the Corporation for their full power load was 0·9d. per unit.

Mr. A. J. CRIDGE (Sheffield Corporation Electricity Supply Department) criticised Mr. Snell's contention that the prices charged for power were not high enough to enable undertakings to conduct their business on a sound commercial basis, and said that if higher prices were charged they would get no customers at all.

Mr. J. W. BEAUCHAMP (Chief Assistant Engineer, Sheffield Corporation Electricity Supply Department), referring to Table III. and the column "Units per Capita," asked if it was possible to obtain the consumption of power per unit of turnover. In a jobbing engineering works with which he was acquainted, the cost of power worked out at 5 per cent. on the turnover.

Mr. H. DICKINSON (Engineer-in-Chief, Leeds Corporation Electricity Supply Department) said that generating plant in engineering works is often run very badly, and was allowed to get into a very uneconomical condition, and he felt confident the figures quoted by the author in Table I. were not obtained in regular practice. He wished the author had laid greater stress on the convenience to manufacturers of being able to obtain their power from outside sources, instead of generating it themselves. Works managers found it much more advantageous to be able to devote the whole of their time to the production of work, than to have the additional worry entailed by the responsibility of a power plant. His experience showed they were learning to appreciate this fact, and he was confident they would continue to obtain their power from outside, even if called upon to pay a higher price than to-day. Referring to Table VI., he did not agree with the figures quoted for cost of distribution. It was imperative to lay down cables larger than called for by present requirements; the capacity should not be less than double. It would, therefore, be many years before the figure of £12 per kilowatt was obtained. The great difficulty engineers had to face was the high capital cost of the older stations. What originally cost £15 per kw. could now be obtained for £5. They must therefore endeavour to reduce these charges to the present-day level. The diversity factor in Leeds, which he took as the ratio of the sum of the consumers' maximum demands divided by the power load at the station was 2·4.

Mr. E. J. MARSH (Sheffield Corporation Tramways) considered the whole matter a question of a rational system of charging. There had been many systems devised, but all were more or less unsatisfactory. Everyone seemed to have a different way of calculating the diversity factor, which led to much confusion.

Mr. WARDALE (Sheffield) advanced the opinion that the present attitude of the Board of Trade in the case of accidents and the imposition of heavy fines would be an inducement to power users to come on the mains.

Mr. F. W. WARDROBE (Sheffield) laid stress on the question of capital cost, which he considered to be the deciding feature. When manufacturers found they can get reliable power without having to lay down large capital sums, they would readily become customers of a power supply company. The question of spare plant in large works was not such an important item as it was often thought to be. Low power costs could, he thought, only be obtained by the use of alternating current.

Mr. SNELL once more responded to the repeated request for the definition of Diversity Factor, and said it was the sum of all the consumer's maximum demands divided by the maximum demand at the generating station. Despite Mr. Yerbury's criticism, he must still adhere to the opinion that concentration would necessarily result in economy, and was the only practical way to secure reduction in costs. He was glad Mr. Hartnell confirmed his figures with regard to the generating costs of local plants; at the same time there were several points to consider which were favourable to obtaining a supply from outside sources. Space became valuable, and a manufacturer was sometimes glad of an opportunity to get more room by clearing out his own plant. Local nuisances sometimes arose which could be avoided in this manner. During brisk times he was glad to have the opportunity of supplementing his power without installing extra generating plant. When it became a question of permanently increasing the power, he found it advantageous to avail himself of an outside source, when such power was available, rather than to lock up capital in new plant. Replying to Mr. Fedden with reference to the critical load factor and size of plant beyond which it would not be commercially possible for an outside power company to supply, he said, no company could afford to supply a paper mill at a cost of 0·2d.; it would not pay for the cost of the transmission system involved. He knew of two examples where the load factor in steel works is over 20 per cent. With a diversity factor of 1·8, and actual cost per unit of 0·65d., it did not necessarily follow that a consumer could be supplied at that figure. It was necessary to have a maximum demand indicator on a consumer's premises to get at the diversity factor. He did not find any definite ratio between kilowatts installed and kilowatts demanded. Mr. Dickinson had criticised the figure of £12 per kw. for transmission, which he considered too small. Although the present price was about £30, yet it would be quite feasible to obtain the low figure named. Referring to a suggestion made by one speaker that electrical energy should be generated at the pit and transmitted direct to London and other large centres instead of sending the coal by rail, he would say that such a scheme had been seriously considered involving transmission at 30,000 volts, but it was found that the cost would be prohibitive.

* This is extremely high in view of the fact that the tramways are supplied from their own generating station.—ED. E.E.

ACCUMULATOR LOCOMOTIVES FOR MINES

When considering the replacement of steam haulage by an electrical system, two alternatives are available: either a stationary motor driving a rope haulage or electric locomotives may be employed. The former possesses appreciable advantages over a steam gear, in that the power costs are lower, owing to the fact that the generation of power for all purposes is centralised, and the transmission losses are reduced to a minimum. There is also a greater freedom in the choice of the locality of the gear, and the maintenance costs are lessened

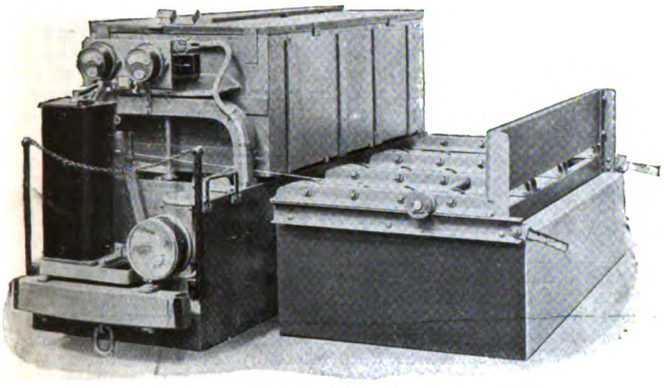

Fig. 1.—Locomotive with Battery in Place.

by the reduced wear and tear of the ropes and track owing to the steadier drive. These gears share with the steam-driven gear, however, two disadvantages. The first of these is the presence on the track of moving ropes and guide rollers, and the second is inflexibility. They are not suitable for rapid extension as the workings progress, and their use is therefore confined to the main galleries, while the coal is usually hauled from the working face to the main track by ponies. On all scores it is advisable, if possible, to replace animal hauling by a quicker, more efficient, and less costly mechanical system. The only method available is to employ electric locomotives. In a fiery mine, these must be of the accumulator type, on account of the difficulty of rendering the collection of current from an overhead wire absolutely sparkless. Moreover, a system involving the use of accumulator locomotives is more flexible, as it may be extended or removed to a different part of the mine

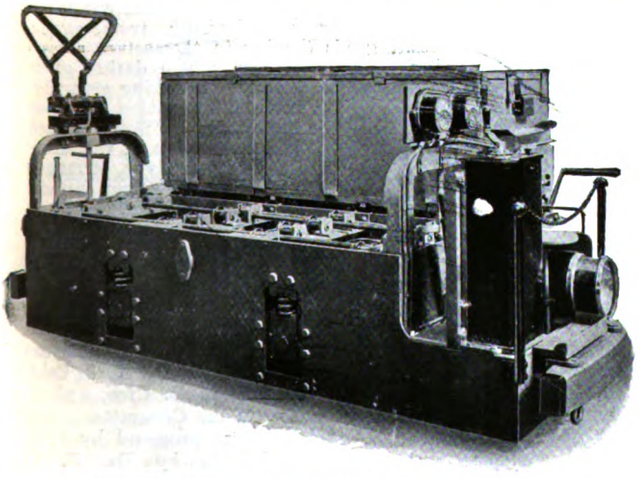

Fig. 2.—Locomotive with Battery Removed.

more easily than a line with a trolley or third rail for collecting the current.

The chief point militating against the success of accumulator locomotives is, of course, the difficulty of obtaining a suitable battery, having a sufficiently large capacity combined with a comparatively small weight. In the system described below, which has been developed by the Felten & Guilleaume-Lahmeyerwerke Co., of Frankfort, this point is in a large measure disposed of by the ease with which the batteries are changed, and the arrangements made for rapidly re-charging them. They are, moreover, of a special type, having a large capacity in proportion to their weight. Charging benches, alongside of which the locomotives may be run, are erected at suitable places.

The locomotive frame is of angle iron, and is covered with iron sheets. It carries three or four rows of four rollers each, which revolve about axes parallel to the longitudinal axis of the locomotive. In addition, two small winch barrels, to which ropes or chains are fastened, are attached to the back and front of the framework. They are keyed to a common shaft, and are turned by means of a crank handle fixed at the back of the locomotive. The charging bench is the same height above the rail level as the top of the locomotive frame, and is equipped with rollers and winches in a similar manner. The battery cases are fitted with two sets of hooks at either end (see Fig. 3), and are fastened to the locomotive by means of catch pins inserted in the end pieces of the framework, which also prevent any tendency of the battery to move backwards or forwards while travelling. To transfer an exhausted battery from a locomotive to the charging bench, the catch pins are removed, and the chains fastened to the charging bench winch barrels are attached to a pair of the hooks on the battery case. A few turns of the handle then rolls the battery on to the bench, and leaves the locomotive free to receive a fresh battery from an adjoining bench. All that remains to render the locomotive ready for

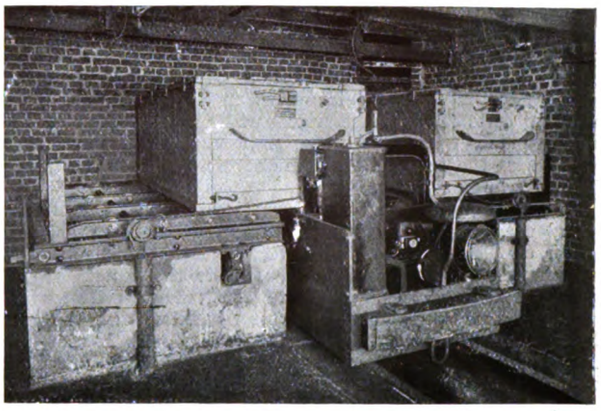

Fig. 3.—View of Locomotive showing Method of Changing Batteries.

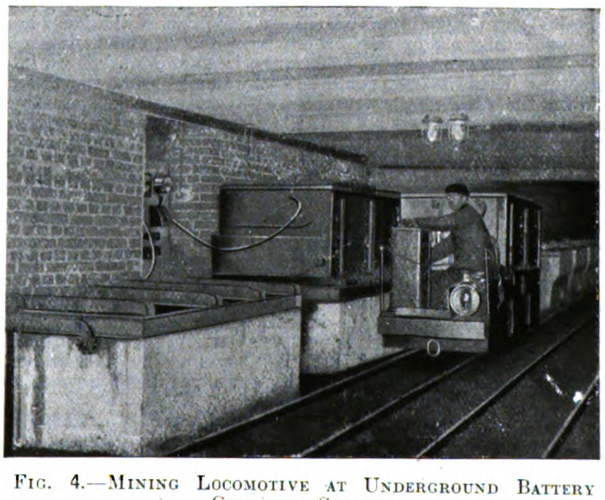

Fig. 4.—Mining Locomotive at Underground Battery Charging Station.

another journey is to insert a plug in a socket on the battery case. The whole process of exchanging an exhausted battery for a fully charged one occupies a minute at most; and is easily accomplished by one man.

The front of the locomotive is fitted with a seat for the driver, round which are grouped in convenient positions the controller, measuring instruments, brake lever, &c. The motors are two in number, and are arranged for series-parallel control. Their combined rating is 19 h.p. The total weight of a locomotive is about 5½ tons, 2½ tons being accounted for by the battery,

Digitized by Google

which consists of 84 cells, type H. J. 100, manufactured by the Accumulatorenfabrik A.-G., of Berlin. At the one-hour discharge rate the battery has a capacity of 74 ampere-hours, which suffices to haul a train of 30 loaded tubs, having a gross weight of about 27 tons, for a distance of two miles on a gradient of 1 in 250 at an average speed of 6½ miles an hour, and to make the return journey with empty tubs. If desired, a battery designed for extremely rapid charging may be supplied, its capacity then falling to 60 ampere-hours on a one-hour discharge rating.

A large number of these locomotives have been delivered by the Felten & Guilleaume-Lahmeyerwerke, and are understood to have given satisfactory results. At the Zeche Margarethe, Sölde, Westphalia, for example, they are now employed in place of ponies, and have resulted in a saving of 50 per cent. in the working costs. In other cases, the economy has been even greater, on account of the conditions of hauling, and the costs of pony-tending. A further point in its favour is that the working costs of a haulage system with electric locomotives may be computed with exactitude, as a contract can usually be made with the accumulator manufacturers to keep the batteries in good working order.

It will be noticed that the locomotive shown in Fig. 2 is provided with a current collector. This may be connected to the motor circuit in place of the battery by means of a change-over switch, and current is then supplied to the motors from an overhead wire. The addition of the current collector is of value in some special cases, as, for example, when the coal is brought out from the mine through a drift, for in this case a large portion of the line is permanently in use, and as the tunnel is well ventilated from the surface, no danger is to be apprehended from slight sparking at the overhead wire. Current may thus be supplied to the motors from this source for part of the journey more economically than from the battery, and the latter will require re-charging less frequently than would otherwise be the case.

DOUBLE FILAMENT LAMP PATENT ACTION

MR. JUSTICE SWINFEN EADY had before him last week the case of True and the Variable Electric Lamp Syndicate, Ltd., *v.* The Bryant Trading Syndicate. The action related to a double filament lamp, and it was alleged that the defendants had infringed two patents taken out by a Mr. Robert Quain, and assigned to the plaintiffs.

The first of these, No. 15,689 of 1901, described a specially designed lamp-holder. This was a ring or tube, the upper end of which was fitted with transverse pins, which fitted into the bayonet points of the ordinary socket. The lower end of the ring or tube was divided into a number of strips by vertical slits, the lower ends of which were opened out. A short distance above these lower ends there was formed a recess with a corresponding rim projecting outwards, and the cap of the lamp had a corresponding rib or ring projecting round it, and fitting into the spring recess in the ring when the lamp was pushed up into its place. Thus the lamp could be freely turned round its vertical axis on the spring recess, and as different contacts were thus put in circuit, either or both of the filaments were rendered incandescent. Thus revolving the lamp a short distance changed its candle power. Although the patentee first described this specially designed holder as an intermediate fitting between the ordinary socket and the lamp, he also pointed out that the special holder might be formed upon a permanent socket, and as part of it, and without any intermediate fitting, and if the upper socket was so formed it would be adapted to receive his lamp with its projecting ring or rib. The third claim in the patent claimed this modified form of the apparatus as a portion of the patented invention. This form of the invention, the judge decided, was practically identical with the apparatus described in the patent of Edison and Hill, 22,327 of 1895, which was a clear anticipation, and the patent No. 15,689 was therefore invalid for want of novelty.

The novelty in the second patent sued upon, No. 18,569 of 1901, was to be found in the cap of the lamp. No special form of holder was required. The lamp was adapted for the bayonet socket-holder in common use. The device which enabled the filaments of different resistance in the same lamp to be used separately or together, consisted of a wire passing completely through a transverse opening in the upper part of the cap, its ends projecting sufficiently to engage in the slots of the bayonet socket. The opening on each side of the lamp through which the wire passed was elongated horizontally, and the wire was pointed in the centre of its length to a vertical point in the centre of the cap. The wire could thus move freely backwards and forwards to the extent of the length of the slot in the cap, and either or both of the contact pieces connected with the filaments could thus be put in circuit.

Until this invention, the judge continued, there was not any variable lamp on the market, without a switch upon the lamp itself, which was capable of being used in the ordinary fittings in common use, and unless some intermediate or adjusting piece was also employed. He had arrived at the conclusion that the invention was new, useful, and had not been anticipated. Hunter and Jacks' patent 3,426 of 1894, he said, was quite different, and Edison and Matthews, 7,530 of 1894, which was also relied upon by the defendants, had nothing to do with the plaintiff's invention. It had also been contended that the plaintiff's claim was invalid, as the second claim was an independent claim for the use of a screw nut upon the end of a wire affixed to the holder, to permit it to change its position, and that the use of such a nut for such a purpose was one of the oldest devices. In the judge's opinion the patentee was merely describing a method of affixing the invention to the holder as an advantageous method of using it where special circumstances rendered it expedient in case of vibration, for instance.

The objection to the plaintiff's second patent failed, and he decided in favour of the validity of the patent. There would be an injunction restraining any further infringement of the plaintiffs' second patent, and the plaintiffs would have the costs of the action, except so far as they were increased by the claim in respect of the first patent.

AN EXAMPLE OF INTERIOR ARC LIGHTING

ONE of the latest examples of interior arc lighting is the extensive installation which has been recently carried out at Messrs. Debenham & Freebody's large premises in Wigmore-street, London, W. Large floor space illumination had to be combined with artistic and hygienic treatment, and the open spaces and considerable freedom from obstruction due to partitions and columns gave opportunity for the use of large units of light spaced at wide intervals, thereby conducing to a considerable economy in current consumption; while at the same time the requirements of even diffusion of light and intrinsic brilliancy at every point were met by the adoption of the indirect as opposed to the direct method of illumination. The type of lamp adopted was that of the Union Electric Company's open inverted arc, and these were fitted with inverted reflectors for the purpose of throwing the light up to the ceiling, where this was sufficiently near the correct hanging level of the lamp to afford a good, even illumination. The reflector used was a 19½ in. diameter enamelled cone, whose interior surface of white threw the light up strongly to the ceiling.

In cases where the ceiling was not sufficiently near the crater of the arc to give a sufficiently strong illumination, it was necessary to fit over-reflectors similar in shape to a Chinese umbrella, and constructed with a surface of vitrified white enamel, measuring 35½ in. in diameter. These were placed approximately 12 in. above the arc, and a small under-reflector measuring 12 in. diameter, was placed immediately below the arc, so as to catch any rays which might fall at an angle greater than about 5 degrees to the horizontal.

The ampere rating of the lamps varied with the illumination required in the different parts of the building. Care was taken to avoid an appearance of shadow on passing, from, say, a department showing light goods (having in themselves a high co-efficient of reflection) to a department where darker goods are displayed and more light is absorbed. Speaking generally, the calculations were based on a useful illumination of about three and a half candle-feet, but in some cases the figure reached the value of five candle-feet. The greater portion of the lamps for the interior lighting were of the 8-ampere type, arranged on the basis of one lamp per 450 to 600 sq. ft. of floor surface. Approximately, 200 arc lamps were used in the building.

Central Technical College Old Students' Association.—The Annual General Meeting and Dinner of the Central Technical College Old Students' Association was held on Saturday last, Prof. W. E. Dalby, President, in the chair. Prof. A. G. Ashcroft, Messrs. M. C. Booth, A. E. Childs, and H. Crompton were elected as additional Vice-Presidents, and Dr. R. J. Caldwell, Messrs. F. C. Lea, F. K. Stevens, E. B. Cree, and R. Whymper were chosen to fill vacancies on the Committee. The toast of the Old Students' Association was proposed by Prof. Raphael Meldola, and was responded to by Dr. E. F. Armstrong, who is the Honorary Secretary and Treasurer of the Association. Prof. H. E. Armstrong proposed the Imperial College of Science and Technology; he alluded to the important research work that had been carried out by old students of his (chemical) department, and expressed the hope that great attention would be given to the subject of fuel economy in the research work of the new college. Sir William White, K.C.B., and Prof. W. A. Tilden (Dean of Royal College of Science) replied. Sir William White said that the new college must be no mere engineering school, but it must be devoted to the highest specialised technical instruction, and Prof. Tilden put forward the claim of pure science for greater recognition. Prof. Dalby gave the health of visitors, and this was acknowledged by Mr. F. G. Ogilvie and Prof. J. Adams. There were over a hundred old students present.

THE "DICK" AUTOMATIC VOLTAGE REGULATOR

IN a previous issue (ELECTRICAL ENGINEERING, Vol. II., page 929) we gave a full description of the electrical equipment of the Vienna-Baden single-phase railway, in which was included a short note referring to the construction and action of the "Dick" voltage regulator, which is in use in the power station of that railway at Leesdorf. We are now able to give some further details of the construction of this regulator, which is manufactured by the Austrian Siemens-Schuckert Co. There are two types manufactured, one for direct-current, and one for alternating current, but the principle is the same in both. The diagram in Fig. 1 shows the connections for either type of

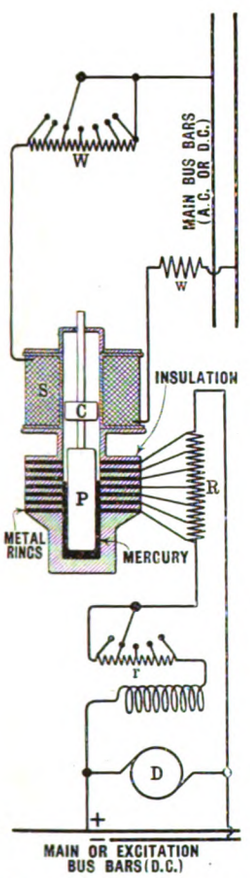

FIG. 1.—DIAGRAM OF CONNECTIONS FOR A REGULATOR OF EITHER TYPE.

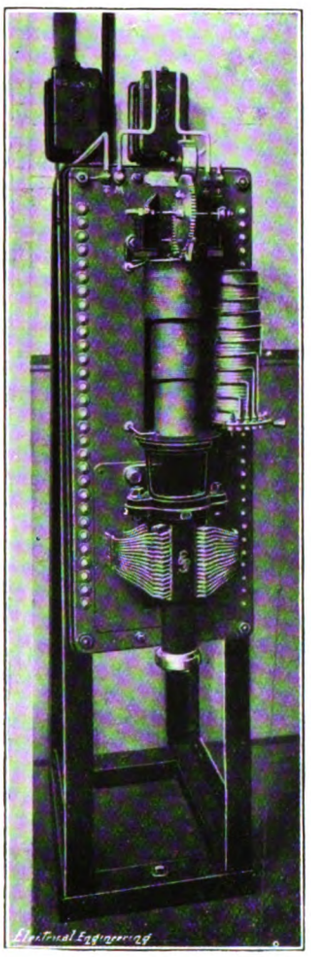

FIG. 2.—REGULATOR FOR USE ON ALTERNATING-CURRENT CIRCUITS.

regulator. The machine D is the main generator, or, in the case of an alternating current system, the exciter. In the shunt field circuit of this machine is an adjusting resistance r, and a regulating resistance R. The latter is divided up into a number of sections, connections being made from these sections to metal rings in the lower portion of the regulator, as shown in the diagram. These metal rings are separated from one another by rings of insulation and are piled up to form a cylinder, the lower end of which is closed, and which contains mercury. A plunger P floats in the cylinder, and by its movement alters the level of the mercury, thereby varying the number of sections of the resistance R, which are short-circuited. To the plunger P is attached an iron core C, which is lifted up by the action of the solenoid S. This solenoid is connected across the mains, the voltage of which is to be regulated, in series with an adjusting resistance W and a series resistance w.

The action is as follows:—If the voltage of the mains falls, the ampere-turns of the solenoid S decrease; the plunger falls and causes the mercury to rise and short-circuit more sections of the resistance R; this causes an increase in the exciting current of the machine D, and a consequent rise in voltage. In the case of a high-pressure alternating-current system, the solenoid S and the resistances W and w are connected in series with the secondary of a transformer, the primary winding of which is across the main high-pressure bus-bars. Fig. 2 shows the type of regulator for use on alternating-current circuits. That used for direct-current working differs only very slightly in external appearance. The solenoid, the connections to the metal rings, and the adjusting resistance are visible, as well as the balance-weight at the top, by which the sensitiveness of the regulator can be varied. The adjustment, in the first place, is made by means of the hand-regulated resistances W and r.

The regulator is supported on a bracket on the wall for the smaller sizes, and, of course, must always be placed upright. The amount of mercury varies from about 8½ oz. in the smallest size to about 6 lb. in the largest size. The mercury must be chemically pure in order that the ring-contacts shall remain clean, and care must be taken that dust does not enter into the cylinder.

Where several alternators are working in parallel and are supplied by one exciter, only one regulator is needed. This is placed in the field circuit of the exciter, as is shown in Fig. 1, and by this means the voltages of all the generators are regulated simultaneously. This is the method in use at the power-station of the Vienna-Baden single-phase railway at Leesdorf. The solenoid S, in series with an adjusting resistance and a series resistance, is in this case in the secondary circuit of an oil transformer which transforms down from 10,000 volts to 110 volts.

An alternative arrangement in the case of an alternating-current generating station is that in which each generator has its own exciter, which may be either shunt or compound wound. Each exciter has a regulator of the continuous-current type in its field circuit, the solenoid of which consists of two windings. The inner windings are connected in parallel across the terminals of a small auxiliary continuous-current generator, driven by a synchronous motor connected to the alternating-current mains. The outer windings are in series, and are in the main circuit of the auxiliary continuous-current generator. In this main circuit are also an adjustable resistance and the variable resistance R of a regulator of the alternating-current type, the solenoid of which is connected to the alternating-current mains, either direct or through a transformer, according as to whether the main voltage is low or high. This arrangement works in the following manner:—The inner windings of the continuous-current regulators tend to hold up the plungers, thus leaving all the sections of the resistances R in circuit. The outer windings act in an opposite direction, and tend to overcome the ampere-turns of the inner windings, thus letting down the plungers and short-circuiting some of the sections of the resistances R. Should the voltage of the system fall, the resistance of the alternating-circuit regulator is short-circuited; the current in the main circuit of the auxiliary generator increases; the outer windings overpower the inner windings, and the field currents of the exciters are increased. The regulators can be adapted to suit practically any arrangement for excitation.

Agricultural Hall Motor Exhibition.—We understand that the thirteenth of the series of annual automobile exhibitions organised by Messrs. Cordingley and Co., at the Agricultural Hall, is to be held from March 21st to 28th. The display of heavy vehicles is to be a feature, and there will be a special "inventors'" section.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the Institution on Thursday:—*As Associate Members.*—W. Clark, H. Cooch, G. F. Dewynter, I. H. Jenkins, C. O. Jolly, A. G. Lee, W. U. Lonnon, F. Pape, H. S. Thompson, A. Wallis. *As Students:*—S. M. Hills, E. Pogson, E. H. Webb.

Post Office Telegraphs and Telephones.—A return has been issued giving a statement of the gross amounts of income and expenditure for the Post Office telegraphs and telephones during the year ended March 31st, 1907. The accounts for the telegraphs and telephones are, unfortunately, not shown separately, but a committee has under consideration modifications in the arrangement of the accounts to render it possible to separate the working of the two branches in future statements. The amount of expenditure in respect of salaries, superannuations, and maintenance is given as £4,027,665, to which is added £118,642 for interest, capital expenditure to the extent of £748,979, and £116,639 expended by other departments, making a total of £5,011,925. The total receipts amounted to £4,369,227, so that the balance of expenditure over receipts was £642,698, a lower deficit than has been shown since 1903.

REVIEWS OF BOOKS

Electric Arc Lamps. By J. Zeidler and J. Lustgarten. 188 pp. 8½ ins. by 5½ ins. 163 illustrations. (London: Harper & Bros.) 5s.

THIS book is an eminently practical study of modern arc lamps, appealing mainly to lighting engineers as a handy unbiassed work of reference, showing the leading types of lamps available, their distinctive features and performances, and the practical conditions determining their choice and arrangement. The descriptions are rigorously confined to modern apparatus suitable for the systems of supply available in the United Kingdom; we have not been able to find, for example, any reference to arc lamps for use on constant-current series circuits. This rigorous limitation adds to the value of the book as an up-to-date guide to the practical man, and argues a praiseworthy self-abnegation on the part of the authors in the use of historical matter. Whilst the preface describes the book as an English edition of a German work written by one of the authors, it reads more like an original work, as descriptions of English apparatus predominate; and it may be added that the style occasionally lapses into a species of colloquialism that is rather distinctly British. An example of this is the repeated statement that the regulating mechanism of alternating-current lamps may be constructed "with an induction motor principle." The first chapter gives a highly compressed statement of the main physical facts and properties of electric arcs, including the relations established by Mrs. Ayrton for the length, P.D., and current in continuous-current arcs. Bremer's discovery is represented—not very happily—as being "that by impregnating carbon pencils with *a metallic salt-like calcium or other rare metallic earth* he was able to obtain a very luminous gas." (The italics are ours.) It was rather the discovery that the fluorides of the earthy metals gave manageable slags or ashes that made it practicable to utilise the previously known qualities of their vapours in the arc.

The second and third chapters describe the "Electrical Principles" and "Construction" of arc lamps, and are generally excellent in clarity and conciseness, covering a number of types of lamps in general use, and their adaptations to different supply conditions. The classification under "Electrical Principles" is determined by the electrical regulating arrangements under the headings "Series," "Shunt," and "Differential"; but this classification cannot be followed when dealing with "Construction," where the natural divisions are "Open Arc," "Flame Arc," and "Enclosed Arc" lamps. This change, combined with rather frequent references backwards and forwards, and to figures on distant pages, produces a somewhat irritating effect when reading the book consecutively, but will probably detract little from its use for reference.

The descriptions of actual lamps are generally clear, and are not too full of detail; and the instructions for testing and adjusting lamps and their accessory resistances, choking coils, &c., are practical and easy to follow. The descriptions and diagrams of circuit connections in Chapter V. will be found particularly useful. The important subject of the choice of carbons is inadequately treated. It is one on which information from the user's point of view is badly wanted.

Chapter IV., on the "Application of the Electric Arc," commences with a study of the yield and distribution of the light given by arc lamps of the various classes, profusely illustrated by diagrams; but the polar diagrams require the current and power consumption to make them complete and comparable. The comparison of efficiency under various supply conditions is not complete, and the alternating arc is particularly sinned against by the omission. The utilisation of the qualities of different kinds and arrangements of arcs is illustrated by certain examples, in which the calculations take due account of the reflective power of the surroundings. This is a very useful chapter.

The book is profusely but somewhat unequally illustrated. The diagrams and detail illustrations of parts are generally clear and good. The poorer blocks are mostly unimportant. Figures 56 and 58 have been exchanged, and therefore disagree with the text references. The two illustrations of interior lighting would have been more instructive if photographed by arc light instead of daylight. We cannot say a good word for the index, but the "Contents" is an admirably full and well-arranged guide to the book; which is, on the whole, so good that a very early opportunity ought to be available for its improvement in the process of revision for a second edition.

The New Physics and its Evolution. By Lucien Poincaré. (Authorised translation of "La Physique Moderne, son evolution.) 344 pp. 7¼ in. by 5 in. (London: Kegan Paul, Trench, Trübner & Co., Ltd.) 5s.

THIS is one of the International Scientific Series, and is translated from the French. It represents an attempt to pass in review all the changes that have taken place in the views of physicists, and all the principal discoveries made in physics, and its practical applications, during the past ten years. The pages of this small volume contain space far too small for the carrying through of such a feat adequately, even though the technical side of the subject is touched upon very slightly. But the principal difficulty in the accomplishment of the task the author has set himself lies in the fact that it is scarcely conceivable that a single brain can grasp all provinces of modern physics, and give expert opinions upon subjects ranging from, say, modern methods of accurate measurement to chemical thermodynamics and the relations of the ether and matter. Nevertheless, on looking through the book, one has to admit that the author proves himself to be a sound scholar, possessed of exceptionally catholic taste and of a rare power of getting at the best route to the heart of many a labyrinthine subject. But though the author professes to set forth the fundamental facts of each branch of physics before discussing the modern developments of that branch, we fear that the extremely condensed form of the preliminary pabulum will prove almost completely non-nutritive to the average reader. Indeed, we think that even ardent students of physics, when they come across portions of the book dealing with branches unfamiliar to them, may find these portions of but small instructiveness. Further, if the reader be a physicist and also a specialist in some technical matter, and will read carefully the part of the book touching upon his own branch of work, he may easily find various evidences of slightly imperfect grasp of proportion. The author is at his best, on the other hand, in the art of taking a broad view of some large region of theoretical physics. For example, he is excellent in the first chapter, on the evolution of physics, where he convinces the reader that the torrent of modern discoveries is not revolutionary, but only evolutionary, and that to-day we add to ordered knowledge at a greater rate than did our grandfathers, only because the number of seekers has increased in all countries, while their quality has not diminished. In such vein the author very happily and very cleverly discusses many matters of wide and general interest to physicists, and thus makes the book well worth perusal by all to whom physics is important.

ELECTRICAL EQUIPMENT OF SHIPS

A PAPER dealing with the electrical equipment of ships was read on February 12th by Mr. W. D. KIRKPATRICK, before the Liverpool Engineering Society. The author commenced his Paper by referring to the important objection which had been raised to the introduction of electrical machinery on board ship, that is, the effect upon the compasses. Various devices, he said, had been designed to overcome this difficulty, and about 1895 the ironclad dynamo was introduced for this purpose, and was largely used by the British Admiralty. The external magnetic field in this type of machine is reduced by about one half. The armouring also forms a valuable protection against shot and shell if the machine is in an exposed position. It has, however, also the effect of increasing the total weight by about 60 per cent. for the same output, compared with an ordinary unenclosed dynamo. This has led to the general adoption of the 4 and 6 pole machine of the open type, which combines a minimum of external leakage with a maximum of accessibility to the brushholders, and is at the same time self-ventilating.

With regard to the system of wiring on board ship, the usual insulated two-wire system is now used; but in the early days of electric lighting a single wire was used throughout, the ironwork of the ship being treated as a negative or return conductor. The protection of the cables is to a large extent done by means of wood casing, a form of protection which is especially applicable to cabin and saloon fittings. When, however, cables and wiring have to be carried through engine and boiler rooms and cargo space, screwed conduit or galvanised iron tubing is used for this purpose. Cables armoured with galvanised wire have also been used with some success, but this has been found unsuitable for cargo space work, especially if cattle are carried, as the iron wire appears to perish rapidly. Cable tarred and braided over the armouring has proved itself most durable under these conditions. In the British Navy only vulcanised rubber lead-covered cables are used, run on teak battens fixed to the bulkhead, and secured by brass clips. In some foreign navies, notably that of the Japanese, the cables and wires are attached directly to the bulkheads, without teak backing being used. This method, in the author's opinion, is for some reasons preferable to the British practice, but he points out that it entails considerably more holes being drilled in the bulkheads, which is at all times objectionable, owing to the difficulty of making them efficiently water-tight afterwards. The standard voltages for ship work are much lower than those in use for shore purposes, and it is only within very recent years that 100 volts has been exceeded or indeed become general. These low pressures are becoming inconvenient owing to the large sectional area of cable required to convey the current for power purposes.

In a modern steamer there are auxiliary engines distributed all through the ship, affording quite a parallel to a large engineering or shipbuilding works where machinery is widely scattered. In these cases it has been proved by the large adoption of the electric system of power distribution that this system is by far the most economical. The saving is largely due to decreased steam consumption resulting from the use of one well arranged and closely governed engine situated in close proximity to the boilers, instead of a large number of engines at various distances from the boilers, using enormous quantities of steam per i.h.p. The main causes of loss with steam-driven auxiliaries may be taken as:—(1) Condensation. (2) The use of too great a range of temperature in the cylinders. (3) Leakage past valves and pistons due to wear. In order to emphasise the uneconomical use of steam under the second condition, the author considers the case of winches, which must necessarily exert a powerful effort throughout the stroke. When steam at a boiler pressure of, say, 250 lb. is used with cut-off at three-quarter stroke, the waste in not using the steam expansively is very great. The advantages of cables over steam pipes are obvious.

The modern traction type of electric motor with a few modifications would answer all the requirements laid down as essential for ships' use, because the conditions under which it actually works on land are as bad as, if not worse, than those which would have to be contended with at sea.

The main factor is, after all, the question of cost, and in this connection the case cited of a steamer built for a Glasgow firm in 1906 is of interest. She is a boat 350 ft. in length, by 48 ft. beam, and 27 ft. depth, and carries 6,000 tons deadweight. Her main engines are capable of indicating 1,600 h.p., and she has a sea speed of 10·5 knots. When at sea the full load for auxiliary work may be taken as follows:—Air pump, 9 h.p.; circulator, 9 h.p.; feed pumps, 20 h.p.; bilge pumps, 3 h.p.; forced draught fans, 6 h.p.; and lighting dynamo, 20 h.p. This totals up to 67 h.p. The ship is also fitted with eight winches, of which six only would be working at full load at once. Each is capable of developing 12 h.p. The full load in port would therefore be as follows:—Six winches, 72 h.p.; feed pump, 10 h.p.; and lighting dynamo, 12 h.p.; or 94 h.p. in all. To deal with this load it was proposed to install three direct-coupled generating sets, each capable of developing 52 kw. at 100 volts. The cost of the three generating sets, switchboard, and wiring was estimated at £1,870: the cost of the eight winches, including control gear, £848; and the rest of the auxiliary plant, £810. Total, £3,528. The estimated cost of the corresponding steam plant, including a dynamo for lighting, was £2,690. Thus the electrical installation cost £838 more than the steam. The saving in fuel, however, is considerable.

In general, the average steam consumption of the best steam-driven auxiliaries has been shown to be in the neighbourhood of 70 lb. per i.h.p. hour, whilst that of electrical generating sets of the size under consideration is often specified not to exceed 26 to 27 lb. per i.h.p. hour. Taking the b.h.p. : i.h.p. of the latter engine at 93 per cent., the dynamo at 86 per cent., the cables at 95 per cent., and the motors at 78 per cent., an overall efficiency of the electrical installation of 59 per cent. is obtained. This shows that the steam used per b.h.p. on the motor shaft is 44 lb. per hour, representing a reduction of 35 per cent. on the steam consumption of the best steam-driven auxiliaries. In this calculation, however, the assumed i.h.p. of the steam-driven plant is compared with the b.h.p. of motor-driven auxiliaries. The average mechanical efficiency of steam engines, as generally used for this work, may be taken as 70 per cent.; therefore 70 lb. of steam per i.h.p. represents 100 lb. per b.h.p., and the saving of coal due to electric driving is 56 per cent. instead of 35 per cent. On this basis it would be reasonable to expect in the case under consideration a daily saving of 1,800 lb. of coal, or about 240 tons per annum on a working year of 300 days. This coal could not be put on board at much under 15s. per ton, which represents a saving of £180 per annum.

The author then described the electric plant on the new Cunarders *Lusitania* and *Mauretania*. Four electric motors are employed for opening and closing the main exhaust sluice valves, another four for turning the main shafts, whilst six more operate the turbine cover lifting gear. There are also two electric bilge pumps, and three sets of electrically-driven refrigerating machines are fitted forward. These steamers have a generating station composed of four sets of Parsons turbo-generators, each capable of supplying 375 kilowatts or 4,000 amperes at 110 volts. There are altogether about 160 motors on board, varying from the 50 h.p. ones, which drive the forced draught fans, to ¼ h.p. motors, for boot and knife cleaning machines, potato peelers, &c. The passenger lifts, and hoists for the mails, baggage, and galley stores are all electrically driven, as are also the four jib cranes aft. There are some 6,000 lamps of 16 c.p. distributed throughout the ship, of which over 700 are in the engine and boiler rooms. It is interesting to note that nearly 100 tons of copper cable were required to distribute the power about the ship. The Admiralty requirement that the main cables should be placed as far as practicable below the water line, necessitated their passage to the forward parts of the ship to be through the boiler rooms, and in order to withstand the heat they had to be specially prepared with a heat-resisting compound, and afterwards covered with two thicknesses of asbestos braid. In the boiler spaces they are run along the bunker side on porcelain insulators, and are cased in with sheet iron for protection.

One objection to the use of electrically-driven winches, capstans, &c., is that special men are required to work the controllers, as a man accustomed to work with steam would not be able to operate them properly. The gear, however, can be adapted to suit the man who has to work it, and in this connection it is interesting to note one of the latest British Admiralty specifications for control gear, which reads as follows:—

"All control gear is to be designed and constructed so that it shall be unaffected by heavy continuous vibration, such as may proceed from machinery in motion, or sudden, violent shocks as produced by gun-fire. All hand wheels, handles, and levers used in operating the gear are to be of ample size and great strength, and constructed so as to give a good non-slipping grip. They should be of the size and shape usual with steam and hydraulic gear, even though this should be wholly disproportionate to the work they have to do, as they will be used by men accustomed to mechanical gear, and inevitably handled with the usual amount of force. The movement of all levers must be limited by extra strong mechanical stops, and their connection to the gear itself must be such, that the operation of the gear is entirely independent of the force used.

Digitized by Google

All levers to have a motion arranged to move in a manner harmonious with the motion to be produced. All hand wheels are to be arranged so that motion in a counter-clockwise direction completes the circuit, increases the speed or otherwise compares with the effect of opening a steam or hydraulic valve."

The author then referred to a new type of starting switch, the multiple lever switch. This consists of a number of switches, instead of a single contact-arm and a row of contact-segments. These are arranged so that each time a hand lever is moved forward and backward, a switch is closed, and the resistance in the armature circuit of the motor is gradually cut out. In this device each single switch is arranged to be held in position electrically until the last one is closed and the handle released, when all the switches open except the last.

CORRESPONDENCE

ELECTRIC WIRING FOR PLUMBERS.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—A few weeks ago I renewed an appeal which I made a good many years ago, in the columns of one of your contemporaries, on behalf of the suppression of anonymity, on the ground that where reviewers, writing anonymously, make definite statements of fact, it is against the interests of the profession generally, that owing to the anonymity the statements cannot be tested. I now beg to make a similar appeal to you, on the stronger, I trust in your opinion, the far stronger ground, of the dignity of literature, and of the good name of the journal you have so recently established, and for which you claim our suffrages. I need hardly explain that my appeal is caused by the very small review of my book on "Wiring for Plumbers, &c.," which appears in your current issue. I venture to say that the statement made in the review is such as should never be made in a journal having a good name to maintain. It is such a statement as might have been made by a giggling boarding-school miss of the early Victorian era. The modern athletic girl would scorn it. I submit that both the dignity of literature, and the position of your own journal, as a serious representative of what is now an important industry, are distinctly compromised by the insertion of such childish matter under the name of a review.

The ridiculous nature of the so-called review is perhaps somewhat accentuated by the fact that, if your reviewer is able to earn a living more or less directly owing to the establishment of an electrical industry, he owes it very largely to the work that was done by myself and others, who were in the fighting line when probably he was in his cradle, possibly before he was born.

I trust that I am not mistaken, even in this very effeminate reviewer, when I say that he would hardly have written such stuff over his own signature.

Yours very truly,
SYDNEY F. WALKER.

Bath. February 21st, 1908.

[The review to which Mr. Walker takes exception was on his book, "Electric Wiring and Fitting for Plumbers and Gasfitters," and was as follows:—"In the unlikely event of our employing a plumber or gasfitter for electric wiring and fitting, we should give the preference to one who had not read Mr. Walker's book." In reply to his letter we need only quote a few passages from the book:—

"In many towns also, an apparatus is fixed in the neighbourhood of the meter, known as a demand indicator, an arrangement for discriminating between the current taken during certain hours when everybody wants it, and that taken during the remainder of the 24 hours when scarcely anybody wants it, the charge for the former being very much higher than for the latter."

"The terms 3-watt, 3½-watt, 4-watt lamps, &c., refer to what is called the efficiency of the lamp, the amount of light given for a given expenditure of current and pressure."

"The watt is the electrical unit corresponding to the foot pound in mechanics."

"Two kilowatts expended in half an hour equal one kilowatt hour, and 20 kilowatts expended in 20 hours equal 20 kilowatt hours."

"To the author's mind this arrangement [looping in] is only allowable in very special cases, such as where there are several lamps in the window of a tradesman's shop, or several lamps close together, pendant from a ceiling, as in a drawing office, or in an office with a number of desks. He very much prefers that each lamp should have its own pair of wires from the last distribution board."

"Thus each lamp should be protected by its own fuse; each branch circuit, as explained, is also protected by its own fuse, and so on, the fuses being larger in proportion as the currents they have to deal with increase."

"The connection made between the tube and one conductor will do no harm, so long as no second connection is made between the tube and the other conductor."

"Another simple test that plumbers can carry out if they have access to the current for which the wiring is to be done, but which requires care, is to take a piece of tube, say 2 ft. in length, being careful that the enamel is perfect on it everywhere, and make a circuit, as for an electric light service, from the supply wires to the tube, including a switch and an ampere meter. [This figure shows the length of conduit connected through fuses and an ammeter across the supply cables.] Connection may be made to the tube by binding a clean, thin, naked copper wire at each end of the tube, outside of the enamel, but so as not to injure the enamel. . . . In place of using binding wires in the manner described, metallic plugs may be pushed into the ends of the tube."

We leave our readers to judge whether the book merited a longer or more favourable notice.—ED. E. E.]

Electric Clocks.—Mr. H. H. Cunynghame, C.B., delivered the sixth and last of a series of Cantor Lectures upon "The Theory and Practice of Clock-making," at the Royal Society of Arts on Monday, and devoted himself to electric clocks, which he regarded as the clocks of the future. The main advantages of electric clocks were that the wheel train was done away with altogether, and they were much cheaper and simpler. The great obstacle was to get a constant battery, one that would continue in good working order for four or five years. This would be quite possible once the difficulty of the contacts was got over, as he had every belief it would at no very distant time. Electric clocks could be divided into several groups. The earliest form was to have an electromagnet which attracted a mass of iron placed at the end of the pendulum rod. The drawback to this system was that in making and breaking contact the spark which occurred tended to oxidise the metal and create an imperfect contact. In connection with this primitive form of clock, instead of having a battery, the inventors sometimes buried zinc and copper in the garden. The objection to it was that the accuracy depended upon the constancy of the battery. One of the first attempts to obviate this difficulty was made by Hipps, although, he believed, the principle was invented by the French experimenter, Foucault. This system, known as the Hipps' butterfly escapement, consisted of a pendulum having an armature at its end moving over contact springs; to the pendulum is attached a flipper which, when the swing of the pendulum becomes too slow, causes the pendulum to make contact with the springs and thus to receive an electrical impulse, which sets the pendulum moving again. This system did away with the difficulty of the want of constancy in the battery to a great extent, because the number of impulses were largely reduced. On the whole, it had done its work very well, and one clock driven in this manner was still working satisfactorily in the Swiss Government Observatory at Neuchatel. The reason advanced for this working better than any others Hipps' clock made, was that very great care had been taken to make the electromagnet of the finest iron. In other places this type of clock had not worked so well. An ingenious clock had been invented by Féry, which the lecturer could not describe on account of patent questions. But it worked with a polarised bob, and the inventor believed he had obtained a really constant battery. Another class of clock was that known as *train remontoir*, or self-winding clocks, the general principle of which was that a falling weight operated a tumbler switch which closed an electric circuit, and put into motion a motor which wound the clock up, the circuit being broken when the weight made another contact at the end of the wind. There were many systems of this nature, including those of Allen, Webber, and Hope Jones. Next there was the "Magneta" system, which was based upon the principle adopted by Wheatstone in his early telegraphic experiments, in which he dispensed with the use of a battery and contacts. Against this advantage was the disadvantage that the clocks had to be wound up every day, although, of course, this could be accomplished electrically if necessary. A new system was the Cunynghame—Hope Jones electro gravity detached escapement, in which a flipper on the pendulum catching in a small arm frees it and allows it to drop upon a finely jewelled roller fixed to the pendulum, and this gives the latter an impulse forward. The arm is only weighted with 1½ grammes, but the armature flies forward on to the arm in such a violent way that an excellent contact is secured. Mr. Cunynghame stated that he had had this arrangement under test, and had never known the electrical part to fail. Coming to electric synchronisation, the lecturer regarded as the most simple arrangement that adopted by the Standard Time Co., in which an electromagnetic plunger drops into a cam on the minute hand and thus corrects it if either slow or fast. Cornu's method was very similar. Another plan, invented by Rudd, involved the use of two pendulums, one for time measuring and the other the working pendulum. If the working pendulum is working inaccurately it is corrected each hour by the time pendulum. In conclusion, the lecturer had a few words to say upon the unsatisfactory nature of batteries, which, he said, was mainly due to the impurities in the zinc setting up local action, and the formation of zinc crystals on the carbon side. His own opinion was that the best form of battery would be a large size gravity Daniell. He advocated the use of large batteries with not too strong chemicals.

DIRECT-CURRENT TURBO-GENERATORS

THE Paper read by Mr. W. Hoult before the Manchester Local Section of the Institution of Electrical Engineers, on Tuesday, February 18th, dealt chiefly with the commutation and other commutator difficulties in the design and construction of large direct-current turbo-generators. The author referred to the pioneer work of Messrs. Parsons, and then went on to point out that owing to the high peripheral speed of the armature and commutator, great difficulties have arisen in the mechanical and electrical design, requiring much experimental work and careful attention to each detail. Until the last few years the position of the brushes had to be adjusted for variations of load. Messrs. Parsons have an automatic brush control which is actuated by the initial pressure of steam in the turbine. This control gear is working very successfully on many sets, even on traction loads. It has, however, a tendency to lag, and other disadvantages, and is not now fitted, as special windings are used to obtain a fixed brush position with varying loads.

The methods mostly used may be put under three headings :—(1) By compensating windings; (2) by commutation poles; (3) by a combination of compensation windings and commutation poles. In the first method windings which are in series with the armature are placed in slots in the pole-shoes, so that at all loads their ampere-turns are equal but of opposite direction to the armature ampere-turns, thus balancing all armature reaction. Sparking due to distortion is thus prevented, but that due to the current reversal in the short-circuited coil is left, to overcome which either the brushes are given a lead or the machine is over-compensated. This method, which in principle was first suggested by Fischer-Hinnen, was patented in 1893 by Prof. H. J. Ryan, but was allowed to lapse for the reason that manufacturers, being able to build machines to give every satisfaction with natural commutation, would not take it up. A patent for a similar winding was taken out in 1903 by Messrs. Parsons and Stoney. In the second method auxiliary poles placed midway between the main shunt poles are used, through the winding of which the main current or a portion of the main current passes. The object is to give a magnetic field so as to produce in the coil undergoing short circuit by the brush an E.M.F. acting in opposition to its reactance voltage, and of such a value as first to reduce to zero the current present in the coil, and then, while still in opposition to its reactance voltage, to induce a current in the opposite direction, which as the coil leaves the position of short circuit shall have become equal in strength to the current

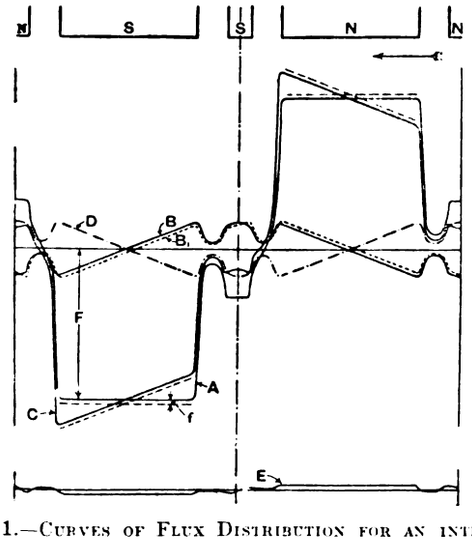

FIG. 1.—CURVES OF FLUX DISTRIBUTION FOR AN INTERPOLE MACHINE WITH COMPENSATING WINDINGS.

of which it then becomes a part. In the third method both compensating windings and commutation poles are used, the former preventing distortion of the main field, and the latter providing a reversing field to overcome the E.M.F. in the coil undergoing short circuit by the brush.

In Fig. 1 curves are drawn showing the flux distribution due to the various windings. Curve *A* shows the flux distribution of the main shunt field and the commutation field separately excited with normal full-load current. Curve *B* shows the flux distribution due to the current in the armature. Curve *C* shows the resultant flux distribution of curves *A* and *B*. Curve *D* shows the flux distribution due to the compensating winding, which for the purposes of making the diagram clearer has been assumed to exactly neutralise that due to armature reaction. Curve *B* being neutralised by curve *D*, the resultant field is that shown by curve *A*, except that the commutation pole flux is much smaller, as in this case ampere-turns are not required on the commutation pole for the armature ampere-turns.

Figs. 2, 3, and 4 are flux distribution curves of a 700-kw. 600-volt generator running at 1,500 revs. per minute, and fitted with commutation poles. The curves were taken by a Duddell

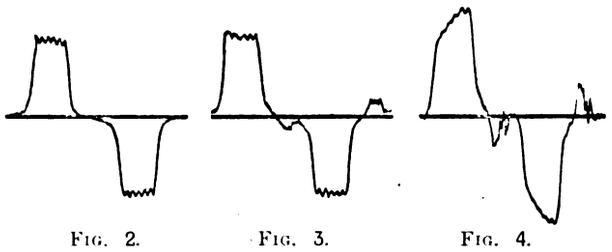

FIG. 2. FIG. 3. FIG. 4.

OSCILLOGRAPH CURVES OF FLUX DISTRIBUTION.

high frequency oscillograph, which was connected to an armature coil by brushes pressing on two of the steel binding rings on the commutator which in turn were connected to two adjacent commutator segments. Fig. 2 shows the shunt field excitation only. Fig. 3 shows the shunt field excitation with the commutation coils separately excited with 300 amperes. Fig. 4 shows the flux distribution with the machine at full load, the current through the commutation coils being 950 amperes. They show plainly the effect of the armature reaction on both the main field flux and the commutation flux. It will be noticed that the commutation flux does not distort the main field at no load.

Fig. 5 shows the field-magnet system of a Siemens 750-kw. 420 to 550-volt direct-current turbo-generator, the photo being taken during the connecting up of the compensating windings. Fig. 6 is a diagram showing the general scheme of connections for a generator with compensating windings and commutation poles. The main drawback of machines fitted with commutation poles alone is that the main field is distorted by the armature reaction, so that the maximum voltage per segment is considerably increased on approaching full load, thus giving a greater tendency for "flashing over" with dust on the commutator. Machines fitted with commutation poles alone can be built about 10 per cent. to 15 per cent. cheaper than those fitted with compensating windings, and for machines in which the maximum voltage per segment can be kept below about 30, and in some cases below 45, they are perfectly satisfactory. It is necessary that the iron of the commutation pole should be worked on the straight part of the magnetisation curve, and consequently at a very low density, in order that the reversing field may increase in the same proportion as the armature current. The correct reversing field can be obtained by adjusting the air-gap of the commutation pole or by means of a diverting resistance in parallel with the commutation pole windings. The former method is that now mostly in use, especially with machines fitted with compensating windings. The air-gap in this case should be designed so large that the correct commutation field can positively not be obtained. When the machine is on test the poles, or preferably the pole-shoes, can be slacked back and iron plates inserted until sparkless commutation and minimum heating of the commutator is obtained. It is quite possible to have perfect commutation and still have considerable heating due to currents in the short-circuited coil.

With large machines fitted with commutation poles only, the correct reversing field is often obtained by means of an adjustable diverter. If new brushes are put on the machine of a quality different from those with which the diverter was set,

Digitized by Google

it is quite possible that to regain sparkless commutation the resistance will require to be altered, which can readily be done if the diverter is adjustable. If an ordinary non-inductive resistance is used as a diverter in parallel with commutation coils, the latter, owing to their being highly inductive, will take less than the normal amount of current on a sudden increase in the load, thus causing momentarily very bad conditions for commutation, which, if the variation is large as on a "short," would cause the machine to flash over on the commutator. To overcome this the diverter winding should

The prejudice created against carbon brushes has been caused to a large extent through their being used on commutators that were not suitable. It is essential for their successful operation that the brushes be kept cool, and consequently the commutator should be specially ventilated and be of a thoroughly sound mechanical construction. The author has made many experiments with carbon, metal, and graphite brushes, and although the latter type of brush is very satisfactory on slow-speed machines, he considers that they are as yet hardly mechanically strong enough for the high speeds of

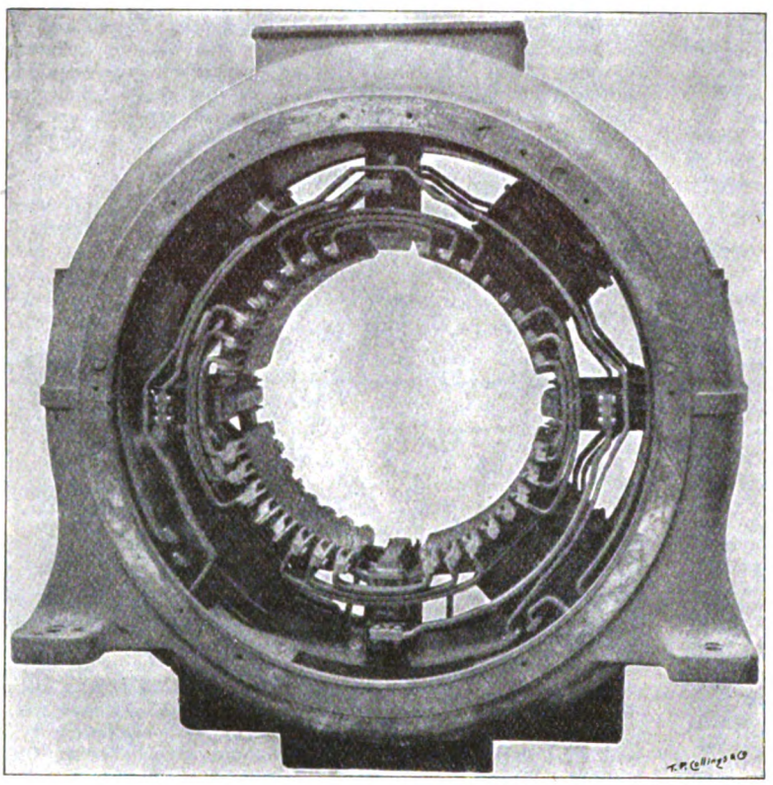

FIG. 5.—FIELD SYSTEM OF SIEMENS 750-KW. TURBO-GENERATOR.

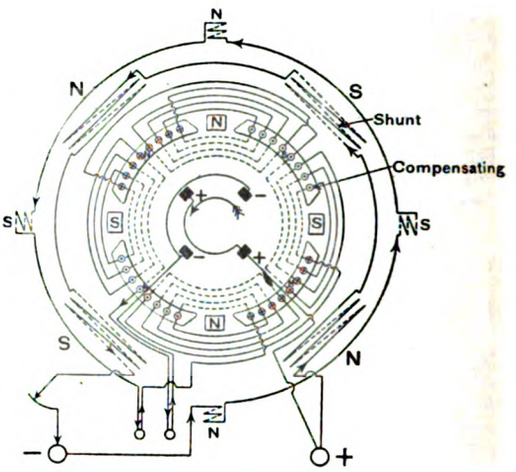

FIG. 6.—DIAGRAM OF CONNECTIONS FOR AN INTERPOLE MACHINE WITH COMPENSATING WINDINGS.

be placed round an iron core with an adjustable air-gap, the air-gap being altered to suit the number of turns through which the current is flowing so that the time constant of the diverter circuit equals that of the commutation system. The diverter can also be arranged so that a larger current than the normal will flow momentarily through the commutation coils so as to hurry up the magnetisation of the commutation poles.

If, instead of having the brushes in the neutral position, they are moved backward, a compounding effect is produced. In Fig. 1 curve B_1 shows the flux distribution due to the current in the armature when the brush is moved backward from its neutral position, so that the armature current has now a compounding effect, the amount (f) being the difference between the ordinates of curves B and B_1, which is shown in curve E. The field under the main pole is then increased from F to $F+f$. The smaller the air-gap the greater will be the compounding effect obtained. In the same way, by assuming the brush position to be moved forward, it can be seen that an under-compounding effect is produced. If the generator is to work on a circuit by itself a compounding effect is an advantage, but if, as is most usual, it has to work in parallel with other machines, it would take the peaks on a fluctuating load. Difficulties have also been experienced with compensated machines working in parallel on traction loads, and Messrs. Parsons brought out a patent in 1900 "to improve the stability" by bringing the equalising connection to tappings on the compensated winding instead of the junction of the compensating winding and the compound winding.

Up to about the last two years all direct-current turbo-generators have been fitted with either metal or a combination of metal and carbon brushes. It has, in fact, often been stated that it was a practical impossibility for high-speed generators to run with carbon brushes alone, but it is now becoming generally recognised that they will supersede the metal brushes in the same way as they have done on slow-speed machines.

turbo-generators. This type of brush is usually made by compressing the graphite in moulds, thus forming a series of layers which easily break away at the leaving edge. In the author's opinion, the only graphite brush of that type capable of being used on a high-speed machine is one in which the layers are in the direction of the running of the commutator, and consequently having the cross resistance in an axial direction instead of tangential. The brushes then do not break away so easily, the commutating qualities are about as good, and advantage of the low friction coefficient is still obtained. Other graphite brushes that were tried, although of a soft nature, ground fine particles of copper from off the commutator that were quite perceptible to the eye.

Endrueit brushes with carbon brushes slightly in advance of them are used to a considerable extent on turbo-generators. These brushes are made by wrapping layers of copper foil and paper together, the whole being then baked so as to form the paper into carbon.

The Boudreaux brush, which is made of a special metal, has very good commutating qualities, but even with a very light pressure it tends to cut the commutator.

Parsons use a brush made of brass wire which usually works on a corrugated commutator. The corrugations increase the area for radiation and decrease the current density at the surface of the brush. Some of their machines are fitted with all the positive brushes in one cell and all the negative in the other.

The author then described the Siemens type of commutator (see ELECTRICAL ENGINEERING, Vol. II., page 882) for large high-speed machines fitted with carbon brushes, and which is constructed as follows:—The commutator bars are provided with tunnels along their entire length, through which the air is drawn axially from each end by the action of a radial fan placed between the two commutator units. The blades of this fan also form the electrical connection between the two com-

Digitized by Google

mutators. The inner unit is cooled by air which passes through channels in the spider close to the shaft. The sides of the shrink rings are protected by specially treated wood plates, which are held in position by a wedge-shaped metal ring, thus ensuring that no connection can be made from the commutator to the shrink rings by dust on the commutator or by flashes from the brushes.

Fig. 7 is a photograph of an armature of a Westinghouse machine having an output of 250 kw. at 3,000 revs. per minute at a pressure of 500 volts. The armature is provided with a radial type commutator, on which it is claimed that carbon brushes can be used at a speed of 3,000 revs. per minute without trouble from chattering, that there are no exposed shrink rings to increase liability to flash over, and that the commutator is kept very cool owing to the large radiating surface. (See also Electrical Engineering, Vol. II., p. 883).

The great advantage of carbon brushes is that when once adjusted they require no attention when the machine is running, and very seldom require attention when the machine is stopped. They also are not sensitive as regards commutation, so that if the commutation poles of the machine are not on the straight part of the saturation curve on overloads, sparkless commutation can still be obtained. It would appear that owing to the much lower current density at which carbon brushes can be worked, that the commutator would require to be proportionately longer, but as the arc of contact can be much greater, owing to the higher surface contact resistance and cross resistance of the brush, the commutator does not of necessity become excessively long.

The drawback to metal brushes and combinations of metal and carbon brushes is, that although perfect commutation can be obtained, they require attention when on load. They may even run for three days without much attention, but although no sparking can be seen by the attendant, considerable sparking takes place under the brush owing to the arc which was originally covered being increased, and this sparking often damages the surface of the commutator. Also owing to their low resistance large currents circulate through the short-circuited coil, especially if the brushes, owing to their adjustments, are not in their correct position. These currents work either with or against the main field and the commutation field, giving a magnetising or demagnetising effect so that if the brushes chatter at all, parallel working with other machines can become very difficult unless the generator has a separate excitation.

Messrs. Brown Boveri, in their turbo-dynamos, have departed from the ordinary construction of magnet frames, the field system of their machines being built up of a number of soft iron core plates in the slots of which the windings are fitted. This gives a continuous inner cylindrical surface, which has the advantage of decreasing windage resistance and allowing silent running.

A striking feature of their machines is that they are fitted, except when a steady source of supply is available, with a direct-coupled exciter, for the purpose of preventing the machine reversing its polarity. On sudden overloads, owing to the turbine dropping in speed, the voltage of the exciter is lessened proportionately, and consequently the generator has not such a tendency to take up all the load if running in parallel with other machines. A separate exciter is of considerable advantage with this type of machine as their fields have not the same tendency to "build" as those with solid field magnets.

As regards the construction of direct-current turbo-generators. Special care must be taken to have all the materials homogeneous and the windings and insulation kept perfectly rigid so that there may be no possibility of their moving either from centrifugal force or variations of temperature. Shafts are usually made of mild steel and run in white metal bearings, which have a spherical seating so that they can follow any whipping of the shaft. Most firms now use former wound armature coils fixed in open slots and held in position by strong fibre wedges, driven into grooves in the armature teeth, so that the pressure is evenly distributed over the entire length, the end windings being held by manganese bronze shrouds. All parts of the armature must be accurately balanced piece by piece as manufactured, and when assembled must be balanced both statically and dynamically as perfectly as possible. Usually arrangements are made so that balance weights can be added at each end of the commutator and at the turbine end of the armature. To obtain the static balance the armature is laid on two well-levelled steel rails with hardened surfaces. When the armature is lying across the rails there are several forces acting. First of all there may be an out-of-balance weight at a certain radius producing a certain torque. The friction between the shaft and the rails causes a torque in opposition to this. The deformation of the shaft causes another torque which is also in opposition. Both the friction torque and the deformation torque can be regarded as constant. The armature will not revolve so long as the torque due to the weight is equal or less than the sum of the friction and deformation torques, so that there is a limit of the angle within which the armature never starts moving of its own accord, even when having an out-of-balance weight. The armature is then revolved until it just reverses of itself. This gives the limit on one side. This position is then marked by a line through the centre which marks the limit. The armature is then revolved in the other direction, and the other limit determined in the same way. By dividing into halves the angle between these two, the position of the out-of-balance weight is found so that the weights to balance this are placed diametrically opposite. The armature is then put so that the line dividing this angle is horizontal. To obtain the weight a thin string attached at the top by a wooden plug is hung over and weights are added until the armature starts to revolve clockwise. The weight is then determined, at which the armature just starts revolving counter-clockwise. The mean of these two weights is then the amount required to balance the armature.

After having been balanced statically, the armature still requires to be balanced dynamically, for if the out-of-balance weight and the balance weights which were put in are not in the same plane perpendicular to the axis, they will act as a couple of forces. This couple must be overcome without altering the static balance, which is done by taking off some of the balance weights, and putting them on the corresponding place at the other end of the armature. If on running the armature up to speed a good balance cannot be obtained by this method, it shows that there is another couple acting in another axial plane. To get rid of this couple equal weights should be put in a diametrically opposite position at the two ends. The two weights are then moved round, always keeping them in opposite

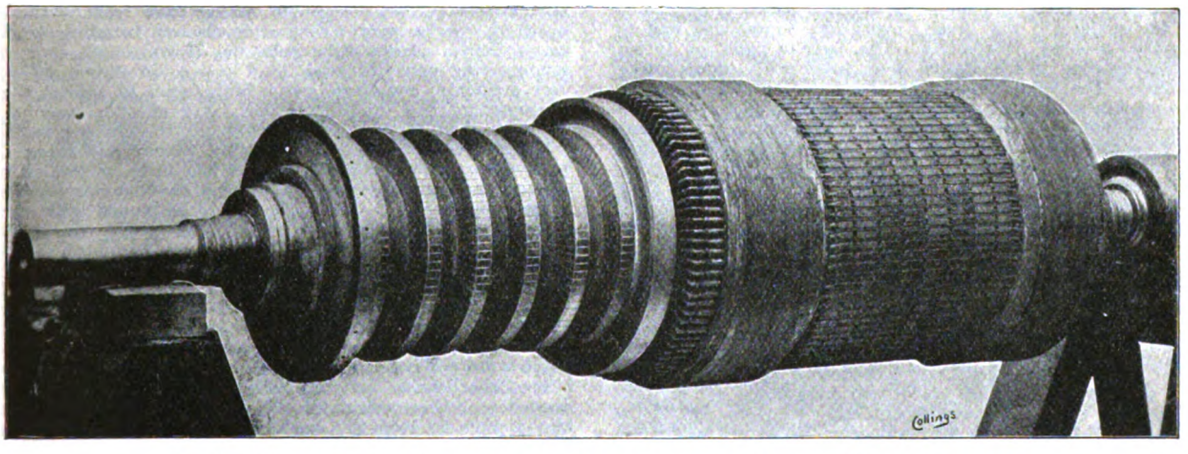

Fig. 7.—Westinghouse Armature and Commutator with Radial Working Surfaces.

Digitized by Google

positions to each other until the place is found where the balancing is best. Then the weights are altered until the vibration disappears. Although the armature may be balanced so that there is no vibration near the machine, it sometimes happens that vibrations appear in another part of the building some distance away. This trouble, however, usually only appears on running up the machine when it may have to pass through its critical speed.

DISCUSSION.

Mr. G. J. STONEY (Messrs. C. A. Parsons & Co.) said that commutation poles had not always proved satisfactory in practice, and that the combination of compensating winding and commutation poles seemed much more satisfactory. It still had its defects, however, and he believed the real solution was to have compensating windings only, and to put on sufficient compensating winding to give a commutation field. In 1885, he said, his firm had tried the compensating winding, but it did not work, because they had only the same number of ampere turns on the compensating field as on the armature. A few years ago they had returned to the same subject, and increased the number to between 2 and 2¼ times the ampere turns on the armature, and immediately got exceedingly good results. The great advantage of having compensating winding only without interpoles is that the lagging of these interpoles with sudden changes of load is avoided. Also, it is not necessary to actually make the compensating winding of any certain amount, so that diverters are not necessary. With compensating winding only, there is a very smooth field in the air-gap, and as a result it is possible to shift the brushes considerably. They had found that metallic brushes were perfectly satisfactory, and there was no trouble whatsoever due to sparking under the brush, and there is no movement of the brushes from no-load to 25 per cent. overload. Carbon brushes require careful treatment, and the number of brushes was much larger than is necessary with brass wire. A great deal has been said about surface-wound armatures as against slotted. They had experimented on the latter, and found that they did not give nearly as good commutation as surface-wound. He did not think the surface-wound were any more likely to break down. Another point about having compensating winding only without commutating poles was that there was no trouble in parallel running. Mr. Stoney then referred to his firm's preference for two-pole as against four-pole designs, and said in conclusion that in his opinion, one advantage of the adoption of compensating winding and surface-wound armatures was that dynamos could be built for much higher speeds than with the ordinary slotted armatures and a mixture of compensating and commutation poles.

Mr. S. L. PEARCE (Chief Electrical Engineer, Manchester Corporation), referred to experiences as to the addition of compensating windings to the old machines installed some six years ago in Dickinson Street, which greatly diminished the brush movement required. They found, however, that the brushes wore away at pretty much the same rate as they did before, a considerable amount of wear and tear going on underneath the surface of the brush; every 336 hours they had to renew the brushes completely. The second type of turbo-machines installed in his station were fitted with commutating poles only. The chief trouble has been due to flashing over. These machines, unlike the Parsons corrugated type, had smooth commutators fitted with carbon brushes. To prevent flashing to earth they had the inside faces of the shrink rings lined with wood. As to the type of brushes, they had tried nearly every brush that was procurable. At the present time they found a successful combination in three "Endruit" brushes, and one hard carbon brush. They had tried the use of external blowers, and these were certainly able to effect a very considerable reduction in the temperature of the commutator bars. His chief criticism was with regard to the mechanical construction of the machine.

Mr. V. A. H. M'COWEN (Chief Electrical Engineer, Salford Corporation) spoke of having ordered Brown Boveri machines for Belfast, and later he has had a 1,000-kw. Brown Boveri machine running in Salford. They had been free from commutator troubles, but the brush expense was very excessive, working out to about ·005d. per unit. These machines were arranged with separate exciters, and as far as parallel running is concerned they had had no trouble at all.

Mr. J. S. PECK (British Westinghouse Co.) thought that, as had been the case with moderate speed machinery, the slotted armature and carbon brush would come to stay. Regarding the ventilation of the commutator, the ventilating duct through the commutating core must certainly reduce the wearing depth very much.

Dr. E. ROSENBERG (British Westinghouse Co.) agreed with Mr. Hoult that carbon brushes were possible, and worked well if the commutator were ventilated. With carbon brushes, good mechanical construction is more important than the composition of the brushes with layers that give a high resistance in the direction of movement of the commutator, although the latter will be preferable from a scientific point of view. With regard to balancing, the operation was very much shortened if arrangements were made to have resonance at a low speed by supporting the bearings by means of springs.

Mr. W. PARKER (Messrs. Siemens Brothers Dynamo Works) outlined some of the considerations which had led to the supercession of the metal brush in ordinary machines, and pointed out how history was repeating itself. An impression got abroad at one time that carbon brushes could not be got to run on commutators at high peripheral speeds without excessive vibration. This, at all events, was the reason why the first turbos designed by the firm which he represented were designed to run with metal brushes. They had now, however, several machines running successfully with carbon brushes. When the question of constructing D.C. turbos with carbon brushes was seriously taken in hand, it was found that the vibration difficulties could be overcome with a suitable brush-holder, and that the real difficulty was the excessive heating of the commutator. In order to overcome this it is absolutely necessary to cool the commutator artificially. With the method of cooling the commutator described in the paper it is possible to keep the temperature rise on the commutator down to about 40° F., with a density in the brushes of about 45 amps. per sq. in. Mr. Hoult in his paper gave the impression that the commutator would be considerably longer with carbon brushes. This, however, is not the case, as the following comparison shows:—With metal brushes the density is kept down to about 130 amps. per sq. in., and the arc of contact to about one-third in., hence the current collected per in. axially of commutator is 43 amps., about. Now with carbon brushes it is possible to increase the arc of contact to 1 in. or more, and the current collected per in. axially is therefore 45, hence the commutator, when fitted with carbon brushes and artificial cooling, is no longer than when fitted with metal brushes.

Mr. G. D. SEATON (Messrs. Willans & Robinson) made a few remarks on the difficulties of mechanical design, and said that, with reference to Mr. M'Cowen's figure of 0·005d. per unit for brush renewals, he understood that in Mr. Pearce's case this amount was about doubled.

Mr. J. D. BAILIE said that failures of binding were almost unknown. Regarding the use of metal brushes, it was quite a common thing with the Parsons commutator for the temperature rise, after long tests of say six to twelve hours' duration, to not exceed 50 to 60 degrees Fahr., frequently 40° F. only, and he did not think that in a well-designed machine the heating of the commutator was in itself quite such a difficulty as was inferred. The heating of the commutator was, in his opinion, caused by the use of the carbon brushes.

Mr. MILES WALKER (British Westinghouse Co.) made a few remarks from the chair. There was one point he would like to bring out, and that was that manufacturers in the future in this matter would not be controlled so much by what they themselves think as by what the users think. However much they might be convinced that a smooth core armature will stand, he was rather afraid they would never be able to convince the user. The same applied to the metal brush. Another point that had not been touched upon was the question of volts per segment. The user in the future would find by experience that machines of high voltage per segment in the commutator were not so satisfactory under difficult conditions of load. Mr. Stoney was perfectly right in saying that from a theoretical point of view a very strong compensating winding was much better than a commutating pole, but if you could show that a commutating pole did work, and you could put it off and on very suddenly, and there was a high factor of safety, then the commutating pole machine would be a cheaper machine than the other, and the user again would buy the cheaper machine.

Mr. HOULT, in reply, said that Mr. Stoney had inferred that with commutation poles the brushes had to be set almost microscopically. He had always found that there was a considerable range through which the brushes could be moved with sparkless commutation, the only difference being that with the brushes in advance of the neutral position, the shunt regulator switch had to be moved further for the same increase of load, owing to the demagnetisation of the main field. Mr. M'Cowen referred to the amount of attention required with the metal brushes in his station and their excessive cost in renewals. The speaker had had machines to run absolutely sparkless with them, but as a brush wore down it, of course, needed to be fed forward, which altered the bearing surface, so that the back of it only was in contact with the commutator. It usually then took the attendant all his time to keep the machine satisfactory. As regards Mr. Peck's reference to the Siemens ventilated commutator, the amount that can be safely turned down is about ⅛ in. so that it will be very many years before a new commutator would be required.

Wireless Communication with Lightships.—A letter has been received by the Margate Corporation from the Board of Trade in reference to the resolution recently passed favouring a system of wireless telegraphy between the Longsand lightship and the shore. The letter from the Board of Trade pointed out that already the establishment of wireless telegraphy had been sanctioned between six lightships and the shore as an experiment, and they were not prepared at present to extend it to the Longsand lightship, as from the short time it had been in operation the Board had been unable to form an opinion as to the success or otherwise of the experiment.

TESTS OF A LIVE STEAM FEED-WATER HEATER

A DESCRIPTION of a series of tests undertaken by Prof. Goodman and Mr. D. R. Maclachlan, of Leeds, with the object of determining the gain in boiler efficiency obtainable by the use of live steam feed-water heaters, is contained in a Paper read by these authors at last Friday's meeting of the Institution of Mechanical Engineers. The tests were made upon a boiler of the "dry back" type manufactured by Messrs. Davey, Paxman & Co., of Chelmsford, 8 ft. in diameter, 14 ft. in length, with 60 tubes, each 3 in. in diameter. In the installation in question the feed-water is supplied by means of a force-pump driven from the cross-head of the main engine; on its way to the boiler it passes through a filter for removing oil, and thence (when in use) through a live steam feed-water heater. The feed-water enters at the top of the heater, and is sprayed into a chamber supplied with live steam from the boiler. The water, falling in a spray through the live steam, attains a temperature nearly equal to that of the live steam, and, collecting at the bottom of the heater, flows by gravity through a non-return valve into the boiler. Cocks are fitted to the heater for the discharge of air which collects in the heater. A small quantity of steam escapes with the discharge of the air, but this quantity was not measured, being practically negligible. The boiler is fitted with an induced-draught fan of the ordinary type, placed at the base of the chimney.

The water was measured in two standard tanks, each holding 1,250 lb., fitted with floats and accurately engraved brass scales. The level in the boiler gauge-glass was taken with the other observations, and care was taken to see that it was the same at the beginning and end of each trial. There was a slight leakage from the blow-off cock, which was allowed for. The drippings from the feed-pump gland were caught and returned to the feed-tank.

In order to ensure the greatest possible accuracy in the coal-measurements and to be absolutely certain that the coal was of the same quality on both days, the whole of the coal required for both tests was previously weighed up in 1-cwt. bags, and a numbered brass tag was tied to each. On the day of the first test, bags bearing "even" numbers were taken for the first six hours, and those bearing "odd" numbers for the second six hours; the remaining bags were used up on the second day. In order to eliminate errors due in estimating the quantity of fuel on the grate at the beginning and end of the trial, in the one the fire and ashes were cleaned out one hour before the test commenced, and the weight of fuel required during that hour was measured and the times of firing noted on the log sheet. The same fire was similarly treated one hour before the end of the trial. The second fire was treated in an exactly similar manner, but half-an-hour before the beginning and end of the test. The working of the fires before the trial, as regards quantity of fuel fired and the times of firing, being exactly the same as that before the end of the trial ensured that the fires were as nearly as possible the same at the end and at the beginning of the trials, both with regard to thickness and composition. The same stoker was employed throughout both trials, and samples of the coal taken periodically were tested.

The results of the two tests show that the boiler evaporated almost exactly the same quantity of water per pound of coal both when the heater was in use and when not in use, the results being even slightly better when the boiler was working without the heater; the actual increase in efficiency was 0·6 per cent. It would be useless to pretend to this degree of accuracy in any boiler trial, and the difference might easily be accounted for by errors of observation, notwithstanding the great care taken to eliminate all errors, but at the same time the authors would point out that with the heater in use the actual heat radiation surface was increased by that of the heater, and if this be taken into account the two tests agree even more closely. They are therefore forced to the conclusion that the heater has no material effect on the economy of the boiler, but from all appearances the deposit in the boiler is materially less when the heater is in use than when the feed-water passes direct to the boiler. The authors have assumed that the steam was dry and saturated throughout the tests, and from the fact that the boiler was not forced and the steam was taken off quite steadily and at practically the same rate on both days, they do not see any reason for believing that it was other than dry, but whether so or not, it was the same on both occasions, and therefore the results are strictly comparable.

CATALOGUES AND PAMPHLETS RECEIVED

FACTORY LIGHTING.—A neat little booklet from the Union Electric Co. points out the economic advantages of good lighting in factories, and putting forward the claim of the various types of "Union" arc lamps for this class of work.

TESTING LABORATORY.—We have received from the Westminster Electrical Testing Laboratory a booklet giving the scale of fees for all conditions of testing work. Lamps, instruments, transformers, and small machines can be tested at the laboratory. Special fees are quoted for outside work, and a list of instruments kept for hire is appended.

ARC LAMPS.—A new leaflet from the Union Electric Co. is devoted to alternating-current arc lamps. The types dealt with comprise a differentially-wound enclosed lamp for 45 burning hours, in sizes from 8 to 12 amperes, and the "Kohinoor" series-wound semi-enclosed lamp for 4 to 6 amperes, giving 20 burning hours. Each type is listed with several patterns of cover, and a full series of accessories is included.

GAS AND WATER-TIGHT TREMBLING BELL.—We have received from the Sterling Telephone & Electric Co. a description and a full-size drawing of their trembling bell for use on mines, railways, and ships. The entire mechanism, exclusive of hammer and gong, is in a hermetically-sealed chamber, the motion being transmitted to the hammer by means of a german-silver diaphragm. A pamphlet, issued by the same company, describes water-tight telephones for use under similar conditions.

INSULATING MATERIALS.—A new list issued by Messrs. A. Cort & Co., of Camberwell, contains full particulars of their various qualities of vulcanised fibre for electrical and other engineering purposes. The uses of fibre and its advantages over rubber and leather for many purposes are pointed out. Particulars of the ebonite, gutta-percha, and vulcanite sheets, rods, &c., manufactured by the company, and a list of their balata, gutta-percha, and cotton driving belts are included.

STORAGE BATTERIES.—An illustrated pamphlet issued by the Chloride Electrical Storage Co., of Manchester, describes the battery-booster plant installed at the North Wall Electricity Works of the Dublin Port and Docks Board. The load on the station will ultimately include a number of crane and capstan motors, and will consequently be very variable. The battery consists of 240 "chloride" cells, with a capacity of 840 ampere-hours at the 9-hour rate, and is in series with a Highfield reversible booster.

INSTALLATION RULES.—The Royal Insurance Company have issued a booklet in which are reprinted the wiring rules of the Institution of Electrical Engineers. The importance of contractors making themselves acquainted with these rules is emphasised in an introduction where the principal ways in which fires are liable to be produced in imperfect electrical installations are summarised. Extracts are also given from the 1905 Board of Trade medium pressure regulations, and the Home Office special rules for mines.

Wireless Telegraphy.—Mr. G. Marconi delivered a lecture on wireless telegraphy before the Liverpool Chamber of Commerce on Monday. He stated that 90,000 words of "commercial" messages had been transmitted between the Company's stations in Canada and Ireland, and that it was now possible to transmit at the rate of 100 words per minute, but a speed of 20 words per minute was that regularly maintained. A 2,000-word wireless telegram from New York had been printed in that day's *Times*.

Flour Bleaching Processes.—On Saturday Mr. Justice Parker delivered judgment in an action taken by the Flour Oxidisation Co., against Messrs. Carr & Co., for infringement of patent in respect of processes for improving the quality of recently ground flour, and for the revocation of Andrews' patent No. 1661 of 1901. The infringement alleged is the use by the defendants of the Alsop process as described in Alsop's patent No. 14006 of 1903, and it was further alleged that the system adopted by Andrews was anticipated by two previous patents taken out, one in 1897, and the other in 1898. After carefully weighing the evidence, Mr. Justice Parker stated that he had come to the conclusion that the only point for him to take into consideration was want of novelty in Andrews' patent. Carefully considering the alleged anticipation, he had come to the conclusion that these did not specify the use of ozone, but nitrogen oxides, although the patent hinted at the possibility of ozone being used in this connection; in other words, Andrews had put into effect what had been previously suggested, but not acted upon. He failed to see that this could be claimed as an anticipation, and had come to the conclusion that neither of the patents relied upon could be regarded as prior publication of Andrews' invention. He therefore found for the defendants, and granted a stay for a month to give the plaintiffs an opportunity of appealing. It may be pointed out that the action for the revocation of patent No. 14006 of 1903, granted to J. C. Alsop, and which has been declared invalid by the Courts (ELECTRICAL ENGINEERING, Vol. II., pp. 206 and 782), will shortly come before the House of Lords, when, if the appeal is successful, the judgment above given will not hold good.

DISCUSSION ON DYNAMO DESIGN AT BIRMINGHAM

THE Paper by Messrs. F. T. Wall and S. P. Smith on the eddy-current losses in the pole-shoes of dynamo-electric machines, which was read and discussed at Newcastle on February 3rd (see ELECTRICAL ENGINEERING, February 13th, p. 241), was re-read and discussed at Birmingham on February 12th. Mr. Wall's Paper on the reluctance of the air-gap (see ELECTRICAL ENGINEERING, Vol. II., p. 965) was also read and discussed. In the former Paper the authors described an experimental method of measuring the eddy-current losses in pole-shoes, and curves showing how these losses depended on speed, flux-density, and the relation of the air-gap to the slot opening. In the latter paper Mr. Wall described some experiments made to determine the flux distribution with toothed armatures.

Dr. W. E. SUMPNER (Municipal Technical School, Birmingham), in opening the discussion to the first Paper, said that the curves of experimental results would be found valuable, but the empirical formula given was far too complicated for ordinary use, and had no theoretical justification.

Mr. J. D. COALES (Birmingham) thought that the method of varying the air-gap, adopted by the authors, would not keep the reluctance of the circuit quite constant owing to the changes produced in the distribution of the lines in the neighbourhood of the teeth.

Prof. G. KAPP (Birmingham University) asked why the authors considered it necessary to use for electric heating, coils which had very little self-induction. Did the authors use alternating current for heating?

Mr. T. F. WALL (in reply) agreed with Dr. Sumpner that the use of such a formula as that deduced from the experiments is not desirable for practical purposes. The object in putting the results in that form was to compare them with the values as deduced from theoretical considerations. With reference to Prof. Kapp's remarks as to the winding of the auxiliary heating coils, these were wound two in one slot, so that they could be connected up non-inductively, the object being to get rid as far as possible of the flux due to the currents in the coils, which were heated by direct current. Another method by which these losses could be measured was by "running down" curves. All that is necessary is in the first place to have a machine in which the air-gap under one pole could be varied. Then by choosing a gap so large that there would be no appreciable loss due to flux pulsations a "running down" curve would be taken and the power dissipated by all the losses in the machine deduced in the usual way from this curve. The air-gap under the experimental pole would then be reduced to a value which would allow of eddy current losses in the pole-shoe, and, keeping the flux density constant, another "running down" curve would be taken. The power deduced from this latter curve would then give all the losses occurring in the first case, plus the losses due to eddy currents in the pole-shoes, and by simply subtracting the results the losses could be at once deduced.

The CHAIRMAN (Prof. Kapp) then called for a discussion on Mr. Wall's Paper on "The Reluctance of the Air-Gap in Dynamo Machines."

Mr. H. B. MATTHEWS (Birmingham) described some experiments which he had made on a machine with semi-enclosed slots. The flux distribution curves which he had obtained were sinusoidal.

MR. J. D. COALES (Birmingham) pointed out that the flux densities in the teeth used by the author were rather low, and asked if this was because the research was undertaken mainly with reference to induction motors. A comparison of Figs. 9 and 13 (ELECTRICAL ENGINEERING, Vol. II., p. 966), for which the air-gap lengths were equal, showed that the general distribution of flux was the same in each case, although the flux density of Fig. 13 was twice that of Fig. 9. This would seem to show that the variation of the permeability of the teeth with flux density had not yet begun to make itself felt.

Dr. W. E. SUMPNER said that he would like to know the exact meaning of the curves in Figs. 9 and 13. He presumed that the ordinates represented the density of the lines of force on the surface of the iron. Mr. Wall's curves did not give the density in the actual air-gap, where the irregularities due to the slots, although appreciable, would be much less than those indicated in the curves. Moreover, these curves did not indicate the wave form of the electromotive force induced in the conductors, especially if these conductors were imbedded in slots. The induced electromotive force was the product of the flux density at the conductor into the speed at which the lines crossed the conductor. It must be remembered that for conductors in slots, while the flux density may be low, the relative speed of the flux and conductor is much greater than the relative speed of conductor and pole. Hence the static distribution of the flux afforded little indication of the wave form of the electromotive force.

Mr. T. F. WALL (in reply) said that the curves given by Mr. Matthews afforded a useful comparison of results, although, of course, since mean values are dealt with in this case, the peaks shown in Figs. 7, 9, 11, and 13 could not be determined. In reply to Mr. Coales, he thought that if the flux density were increased to such an extent that the permeability would be appreciably affected, the peaks shown in Figs. 7, 9, &c., would be correspondingly smoothed out. As Dr. Sumpner remarked, the curves of Figs. 9, 13, &c., show the flux density at the surface of the iron and not in the actual air-gap.

NATIONAL TELEPHONE CO.

THE ordinary general meeting was held on Thursday, Mr. G. Franklin, president, presiding, when the report and accounts given in our issue for February 13th were adopted. The chairman said he thought the result of the working for the year ended December 31st, 1907, would be perfectly satisfactory to the shareholders. The income had increased by £145,346 during the December half-year over the corresponding period of 1906; Post Office royalties had increased by £14,121, and the working expenses had increased by £69,840. Dealing with various items of the working expenditure, he made reference to the increase of £9,637 in rent, rates and taxes, and insurance, which, he said, was largely due to the liabilities imposed upon the company under the Workmen's Compensation Act. For the complete year 1907, there had been an increase of £265,223 in the income, working expenses had increased by £127,863, and Post Office royalties had increased by £26,071. The net result was an increase of £111,299. Working expenses were 63·59 per cent. of the income, compared with 62·60 per cent. He thought the large increase in revenue was entirely due to the large capital expenditure of recent years, and he gave the following figures of capital expenditure during the past three years: 1905, £975,119; 1906, £1,129,671; 1907, £1,129,511. The capital cost per station was now £30 5s. 11d., compared with £30 9s. 1d. twelve months ago. The total capital expenditure to date, including land and buildings, was £14,198,072, against share and debenture capital subscribed of £11,113,174, leaving £3,084,898 provided from revenue sources. It had been asked where was this reserve, and how was it represented, and his reply was that it was invested in the business, and to the extent of over £650,000 in freehold and leasehold properties. The number of stations had increased during the year by 39,372, which was ample evidence of the vitality of the company's business. Most of these stations were upon the measured rate, which was coming into universal use as a consequence of the evils which experience had shown to result from the unlimited service rate. In the course of his reply to the deputation which recently waited upon him in this connection, the Postmaster-General said:—"I have had a certain number of cases taken out—a considerable number—and it appears that on the average five years ago, when they first began their flat rate, they were using 3,000 calls in the course of the year. In five years these same subscribers on the average have increased their calls from 3,000 to 11,000. In no single case have they taken a second line; they are using the same line. They are paying no more now for their 11,000 calls than they were five years ago when they were paying on the average of their 3,000 calls." The company had many cases of flat-rate lines used to excess, and to such an extent was this so that 24 per cent. of the total calls had become ineffective owing to the lines being engaged. Some subscribers thought nothing of sending 250 or 300 calls per day along a line, with the result that nobody else could get into communication with them, a state of affairs which was bad both for the subscriber and for other subscribers. It was generally imagined that the cost of a telephone in capital and maintenance was the same, whether the calls were few or many, but the direct contrary was the fact. Moreover, it was peculiar to the telephone business that the larger the number of subscribers, the greater the capital cost per subscriber. For instance, if they had an exchange with 1,000 subscribers, the capital outlay on switchboards and junctions would be £4 per subscriber, but if there were 10,000 subscribers, the capital cost would be £13 per subscriber. For these reasons the directors had felt bound to co-operate with the Postmaster-General to bring into force throughout the provinces a measured service rate system which, he thought, would be justified both

Digitized by Google

to the shareholders and to the subscribers. This system had been adopted, as the result of careful study, in the United States, Austria, Germany, and other European countries, and also in Australia. To attempt the retention of the flat rate was to fly in the face of experience. The critics of the company and its policy were pleased to picture the company as a very prosperous concern, and they were described as an undertaking with watered capital, inferior plant, &c. The fact was that the interest and dividends paid upon the capital had never reached 4¾ per cent. per annum. He wondered how many of those members of Chambers of Commerce who waited upon the Postmaster-General recently were, in their own business, satisfied with such a modest return on their capital as 4¾ per cent. Even taking into account the large reserve, the profits had never exceeded 6¾ per cent., whilst the dividends upon the deferred stock had never exceeded 6 per cent. per annum, a by no means too large return upon a business which, though licensed, was not protected, and which was generally full of difficulties and technicalities. As indicating the growth of the business, he stated that the number of the staff had increased during the year from 6,310 to 7,911, and the number of shareholders from 11,647 to 12,648. The average holding of the shareholders was £593. In reply to questions by shareholders, the chairman stated that the capital cost of the Post Office stations was apparently about £50 per station, but as this referred to London only, it must not be compared with the figure of £30 which he had mentioned. The cost of the Post Office system in London had been increased on account of it being entirely underground. The capital expenditure in Germany was equivalent to about £27 to £28 per station. With regard to new capital, there was a balance in hand of about £560,000. The Board had been legally advised that it would not be possible to attempt at the present moment to settle the legal rights of the various class of shareholders and debenture holders because in 1910 or 1911 the circumstances might be different. At the same time, the directors recognised the difficulties and steps were to be taken to settle the matter at the cost of the company.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

A. SCHLEICHER and G. Schultz describe experiments which they have made upon the rusting of iron, in order to ascertain whether it is a chemical or an electrochemical process (*Stahl und Eisen*, 1908, **28**, 50). The experiments mainly consisted in potential measurements, which they obtained by immersing rusty and clean wrought-iron and cast-iron plates in water and connecting them together. The authors find that if the potential is zero, or if it remains at a constant value, then both the plates employed are affected in the same manner—in other words, they are oxidised to the same extent. A change in the E.M.F. takes place when one plate is more attacked than the other. The greatest E.M.F. which was obtained between two plates of wrought-iron was 0·36 volt, the current measurement being about 0·00018 ampere. When a rusty plate was connected with a clean one, it was found that the clean iron plate acted as cathode, iron being dissolved from the anode plate, and the E.M.F. falling rapidly. Taking a clean wrought-iron plate and connecting it with a clean cast-iron plate, it was found that the cast-iron plate functioned as cathode. The initial E.M.F. fell nearly to zero, but after a time rose again and finally remained constant; in this case both plates became oxidised. Experiments made with wrought-iron turnings and also with cast-iron turnings showed that the metal rusted more rapidly in water containing carbon dioxide than in water from which most of the carbon dioxide had been expelled.

Two Papers were read before the Faraday Society on Tuesday, both being of a highly physical and mathematical nature. The first was by Dr. Veley upon "Hydrolysis as Illustrated by Heats of Neutralisation." The author tried to correlate, so far as data permitted, hydrolysis values with those of heats of neutralisation, as formulæ proposed to calculate out the latter from determinations of the former have raised interesting and important issues. Unfortunately, important lacunæ occur, either the heats of neutralisation have not been determined, or the dilution and initial temperature have been omitted in many hydrolysis values available, or the former have been determined but not the latter. The author hopes that these lacunæ may be filled in by attention being directed to these omissions. In the experimental part of the Paper numbers are given for hydrochlorides of bases not containing carbon, such as ammonia and hydroxylamine. As bases containing carbon, the chloroanilines, phenylhydrazine, and piperidine have been studied.

The other Paper was by Dr. T. Knox, "A Study of the Sulphur Anion and of Complex Sulphur Anions," the substances studied being the red and black modifications of mercuric sulphide. The conclusions arrived at are that the black modification is the less stable owing to its greater solubility in sodium sulphide solution. This is only what one would expect, since when the black sulphide is left in contact with an alkali-sulphide, it spontaneously passes over into the red modification. The influence of temperature upon the solubility was found to be very small. The solubility of the mercuric sulphide in sodium sulphide has been found to depend on the formation of the complex anion HgS_2''. The constant for the formation of the complex from the ions $Hg^{\cdot\cdot}$ and S'' is :—

$$k_2 = \frac{[HgS_2'']}{[Hg^{\cdot\cdot}]\,[S'']^2} = 5{\cdot}1 \times 10^{54}.$$

From this the free energy of the reaction, Q, may be calculated, on the assumption that it does not vary with temperature. The solubility of HgS in Na_2S_2 was found to be about half that in the corresponding Na_2S solutions. The hydrolysis of Na_2S in dilute solutions has been shown to be practically complete. From the hydrolysis constant of Na_2S, the second dissociation constant of H_2S has been calculated. With the aid of the various constants obtained in this investigation, the concentrations of the S'' and other ions in the various sulphide solutions have been calculated.

ELECTRICAL SCIENCE

British and American

The Ether of Space.—On Friday last, at the Royal Institution, the evening discourse was given by Sir Oliver Lodge, who took as his subject "The Ether of Space." Physical action at a distance, the lecturer stated, was impossible; if matter acted upon matter, it was only by means of a connecting medium. When a spring was distorted, the particles of matter of which the spring was composed were merely displaced, it was the connecting medium between the particles that was strained. The ultimate particles of matter could never come in contact with one another. Newton, in order to explain gravitation, had found it necessary to conceive a connecting medium, which, he supposed, filled the interstellar space. This elastic connecting medium, which was universal and omnipresent, was called the Ether, and according to the theory of Prof. Larmor, the ultimate particle of matter, which was called an electron, was merely a point of strain, or a knot in this medium. Round this point of strain there was a slight tendency to rarefaction, a minute stress in the ether. This was an explanation of gravitation; and when a large number of electrons were massed together, the stress in the surrounding ether became enormous. For instance, to hold the moon in its orbit, a steel rod of over 3,000 miles in diameter (one and a half times the diameter of the moon itself) would be necessary. Clerk Maxwell had calculated that this hypothetical stress was, at the surface of the earth, of the nature of 3,000 times the ultimate strength of steel. The ultimate strength of the ether was probably of the nature of 10^{33} dynes per sq. cm., and if all the matter in the universe were in one piece, this value would certainly be exceeded. The essential difference between ether and matter was as follows :—The ether was, as a whole, at rest, was, in fact, our standard of rest; it had the property of elasticity, could be strained, and exhibited the phenomenon of recoil. All potential energy was due to a state of stress in the ether. Matter, on the other hand, could be moved, could effect impact, but could not be strained. Sir Oliver then showed by experiments how fluids in motion possessed the property of rigidity; the water-jet of a Pelton wheel was impenetrable and could be hammered; a chain or a rubber tyre became rigid when in quick motion, and a paper disc acquired solidity when in motion, sufficient to cut through a piece of cardboard. The fluid matter, represented by the air particles of a smoke vortex-ring, was rigid on account of the rotational motion. Not only rigidity, but elasticity, could be imitated by matter in motion. This was shown by Lord Kelvin's model, in which the axes of four rotating rigid bodies were connected together in the form of a square; and the property of elasticity was present along either diagonal. Thus the electron, which possessed the property of rigidity, might be a point of vortex motion in the ether, and elasticity could also be explained by motion. The lecturer said that he looked forward to the time when we could state definitely that ether in motion was the fundamental and unique thing in the material universe. There was no friction between ether and matter; to test this, he had passed a beam of light several times between two discs, which were rotating at

Digitized by Google

an enormous speed, but this had not the slightest effect on the light waves. The lecturer then showed two experiments to illustrate the theory that the ether spins round the line joining an electric charge to a magnetic pole.

A downward force was applied to one extremity of the axis of spin of a gyroscope; the axis was slightly depressed, but rotated in a plane at right angles to the plane of spin. This precessional motion was, therefore, a test for spin. The apparatus to show the electrical analogy consisted of a vertical current-carrying wire, at a short distance from which was a magnetic pole free to rotate. The current, which could be looked upon as an electric charge flowing down the wire, corresponded to the downward force, and a magnetic line of force between pole and wire corresponded to the axis of spin of the gyroscope. When the charge flowed downwards, the magnetic lines of force, and with them the magnet pole, revolved round the wire; if the charge flowed upwards, the pole revolved in the opposite direction. This seemed to indicate that there was an ethereal spin in a direction at right angles to the spin of the magnet round the wire. These three vectors: the direction of flow of the electric charge, and the direction of the magnetic flux, at right-angles to one another, in one plane; and the direction of motion in a plane at right-angles to this, could be said to be the three uniting vectors of the universe. Sir O. Lodge concluded the discourse with some words on inertia, and on the density of the ether. The electron had a mass only one-thousandth of the mass of the hydrogen atom, but the ether itself had a density of about 10^{12} grams per cu. cm., or fifty thousand million times the density of platinum. If the elasticity of the ether was kinetic, *i.e.*, due to motion, the velocity of the vortex spin must be comparable with the translational velocity of ether waves, that is, with the velocity of light; and the consequent amount of kinetic energy stored up in every cu. mm. of space must be about 3×10^{17} kw. hours, or an amount of energy represented by the total output of a million kilowatt power-station working for thirty million years. (See also ELECTRICAL ENGINEERING, Vol. I., p. 655.)

Self-Inductance Calculations.—There are two papers in the January *Bulletin* of the Washington Bureau of Standards, dealing with the accurate calculation of solenoid coils of any number of layers. The one, by L. Cohen, is an improvement of the well-known formula for long solenoids of more than one layer given by Maxwell. Maxwell's formula was developed on the assumption of a uniform field within the coil, which means that the end effects were neglected; but as the author shows, this formula may lead to an error in the inductance as large as 12 per cent., even when the solenoid has a length ten times its radius. In the present Paper, the author proceeds by writing down the self-inductance of each layer separately, and the mutual inductances of all the layers among one another, and then summing these terms with as great accuracy as practicable. The final formula, which is too long for reproduction here, possesses an accuracy of the order one part in five hundred. It ought to be mentioned, however, that the formula is derived on the usual current-sheet assumption, and thus takes no account of the shape of the cross-section of the wire or the thickness of the insulation. In another Paper in the same number of the *Bulletin*, E. B. Rosa indicates a method to calculate very accurately the self-inductance of a coil of any length and any number of layers, wound with insulated round wire, taking account of the shape of the section as well as the thickness of the insulation of the wire. His method rests upon the use of numerical tables of correction, which he has compiled. He starts with the ordinary current-sheet formula of Rayleigh, then by reference to his tables applies the correction for the finite thickness of the winding. At this stage the computed value is the self-inductance of a solenoid wound with square wire of infinitesimal insulation. Three other corrections have now to be applied to allow for the fact that the wire is circular and not square, and that the insulation is of thickness not negligeable. For examples of the actual calculation and for tables of correction, the original Paper must be consulted.

Phosphorescence produced by Canal and Cathode Rays.—In a well-known experiment due to J. J. Thomson, a distinction between the cathode rays and the canal rays produced during the passage of a discharge through a rarefied gas, is well shown by causing each in turn to bombard a sample of lithium chloride contained in the discharge tube. The heavy positive rays (the "canal" rays) produce a bright red light where they strike the salt, while the negative or cathode rays cause a steely-blue phosphorescence. E. Trowbridge has now succeeded in causing cathode rays to produce a red light by their bombardment of lithium chloride, thus abolishing this particular distinction between the two kinds of rays. His experiments are described in the February number of the *American Journal of Science*. The cathode in the tube used was a concave aluminium disc which projected the cathode rays along the tube through the central circular hole in a ring anode. The part of the tube behind the anode was surrounded by a coaxial solenoid carrying a current and producing a longitudinal magnetic field. By adjustment of the position of the solenoid the cathode beam can be concentrated into a sharp focus on a screen bearing lithium chloride, placed at the end of the tube. The solenoid's field acts, in fact, as a sort of magnetic lens, the rays seeking the weakest part of the field. Under the intense bombardment, the screen shows a red spot surrounded by the usual blue phosphorescence. It would seem that the colour difference is, therefore, an effect dependent on the energy delivered per unit area.

Continental

Electrodynamics and the Ether Problem.—W. Ritz, who recently became known as a somewhat successful theoriser on spectrum lines, breaks some very new ground in the February number of the *Annales de Chimie et Physique*. The Paper, which extends over 150 pages, is nothing less than a frontal attack upon the conception of the ether, and an attempt to substitute a modernised emanation theory for the wave-theory of light and electromagnetic radiation. Briefly, he argues that the ether, from being a very rarefied kind of gas, has evaporated into a mere conception of physical space with no assignable properties. Nobody has succeeded in demonstrating the existence of the ether. The aberration of light from extra-terrestrial sources does not decide as between emission and undulation, and there is no known means of bringing the transmissive properties of the ether into evidence except by the intermediary of matter, a procedure which simply begs the question. The finite rate of propagation of radiant energy involves in reality nothing but a time-lag or retardation, and may be introduced into electromagnetic equations as a retardation of potential. As regards the wave-motion of light, there is nothing to prove the existence of wave-trains. All we know is that there are stationary waves at the source, and periodic effects at the receiving end or in intermediate matter, and these are amply covered by postulating a finite rate of propagation across empty space. For those to whom an action at a distance is inconceivable, the author suggests the emission of ultra-mundane particles by electrically charged bodies. He puts forward a system of electromagnetic equations from which the conceptions of "force" are eliminated. They are entirely kinematical, but represent, as he claims, all that we know, and no more. Gravitation falls into line as a second-order effect, and the secular displacement of the perihelion of Mercury finds a complete and satisfactory explanation in the fact that gravitation is propagated with the velocity of light. Michelson's experiment, the stumbling-block to the ether theory, becomes also quite comprehensible. Apart from the stationary ether, the electron theory, as developed by Lorentz, is retained in its entirety.

Mechanism of Band Spectra.—A determined attempt to explain the genesis of band spectra is made in the *Physikalische Zeitschrift* for February 1st by Johannes Stark, the discoverer of the Doppler effect in canal rays. He makes the very natural assumption that the bands are due to the detachable "valency electrons," whereas the lines are due to the internal "ring electrons." The valency electrons revolve about the positive nucleus in orbits having the shape of elongated ellipses, and as they rapidly radiate energy, the ellipse becomes steadily smaller. The stopping and starting at each end of the major axis generates an electromagnetic wave, and the waves so generated coalesce into two bands, one in the red, corresponding to the waves generated at "aphelion," and one in the ultra-violet, generated at "perihelion. These bands taper towards each other. As a rule, we only see the aphelion bands, and this explains why most spectrum bands are sharp on the red side and fade off towards the blue. The author calculates the minimum wave-length of the bands of water, carbonic acid, benzol, and other compounds from Planck's radiation law, and obtains some interesting confirmations of his theory, followed by daring predictions.

Discharge from Metallic Oxides.—Some interesting figures concerning the discharge from metallic oxides are given by F. Deininger in No. 2 of the *Annalen der Physik*. Platinum, tantalum, carbon, nickel, and other substances emit negative electrons at a red heat, and the current so generated attains saturation when they are kept at a negative potential of 20 to 25 volts. Richardson's formula, which, to a first approximation, makes the current density proportional to the square root of the absolute temperature, is found to apply very closely. Covering the metal with an oxide of calcium, strontium, or barium, exerts a very pronounced effect upon the emission of electrons. Not only is the emission enormously increased, but the individual properties of the metal are practically obliterated. Thus, on covering the metals with quicklime, the author obtained saturation current densities of 730, 810, 710, and 750 micro-amperes per square centimetre from platinum, carbon, tantalum, and nickel respectively at 1,150° C., whereas without the oxide the current densities were 0·04, 3, 0·2, and less than 0·01 respectively, even at 1,300° C. It is evident that in the former case the nature of the metal is irrelevant.

Electric Lighting at Mecca.—According to the *Daily Graphic*, an American consular report on the Mecca pilgrimage states that an English firm has been granted the contract for lighting the prophet's sanctuary at Medina with electricity.

Metropolitan Association of Electric Tramway Managers.—The quarterly meeting of the above association was held at the Municipal and County Club, Whitehall, S.W., on Friday, February 14th. A number of subjects of interest to managers in the Metropolitan area were discussed at the meeting.

Digitized by Google

LOCAL NOTES

ABERDEEN: *Deeside Electricity Works.*—The Electricity Committee last week paid an official inspection to the generating station of the Deeside Electricity Supply Co., which it has recently acquired.

ACTON: *Electricity Statistics.*—The accounts for the nine months ended December 31st, 1907, showed a deficiency of £2,781 compared with an estimated deficiency of £1,887.

BAILDON (YORKS.): *Electric Lighting Scheme.*—A scheme for giving a supply of electricity in this district has been submitted by a Baildon firm of electrical engineers, and is now under consideration.

BELFAST: *Automatic Point Controllers.*—At the weekly meeting of the Electrical and Tramway Committee on Monday the tramways manager, Mr. Andrew Nance, recommended the purchase of three sets of Tierney's automatic controllers at £80 each as an experiment. If successful they will be applied to all the points, the total cost being about £3,500. The present system by which the points are moved by boys costs £1,750 per annum.

BERMUDA: *Electric Supply.*—The Bermuda Electric Light, Power and Traction Co. will soon commence to supply current in Hamilton, the capital of the island. This company, an American concern, secured the necessary powers by an Act in 1904, but owing to delay in commencing work, the Hamilton Corporation declared that the rights acquired had been forfeited, and refused the company permission to erect poles, &c. The Government, however, sided with the company, and accorded the necessary permission. To protect existing lines at crossings, two parallel guard wires are used, instead of the network of guard wires, the mesh of which was not to exceed six inches, at first stipulated for in the regulations.

BIRMINGHAM: *Progress of Electrical Undertaking.*—Mr. R. A. Chattock, City Electrical Engineer and Manager, delivered a lecture at the Midland Institute last week, in which he dealt with the Corporation electrical undertaking. He stated that a very small plant was installed in the year 1882, but in a very few years this became overloaded, and in 1889 the Birmingham Electricity Supply Company was formed. In 1900, the Corporation purchased the undertaking from the company, and three years later decided to municipalise the tramways and to work them by electricity. In connection with the new arrangements for supply in the city, the supply of current to large power users was being taken up in a very gratifying manner, especially for rolling mill work, large motors having a capacity of 200 h.p. or 300 h.p. being installed in many instances for this purpose. During the year 1900, when the Corporation purchased the undertaking from the company, the plant capacity was 2,700 kw., but at the present time the capacity of the three generating stations at Dale End, Water Street, and Summer Lane is 16,476 kw., and whereas during 1900 the units sold were 3,040,822, it was anticipated that during the year ending March 31st, 1908, the units sold would reach 21,000,000. The horse-power of motors connected to the mains in 1900 was 550, but at the present moment this amounts to 6,000.

Tramway System.—At the suggestion of the Board of Trade, side gates have been placed to all the new cars to lessen the risk of accidents. The brake invented by Mr. A. W. Maley, of the Leeds Tramway Department, described in ELECTRICAL ENGINEERING, Vol. II., p. 851, has been fitted to three new cars by consent of the Board of Trade for a period of three months, but the manager has been authorised to endeavour to secure the consent of the Board of Trade to their use on all the 30 new cars recently ordered.

The committee report that the Electric Supply Committee, under powers given to the Corporation in their Tramway Acts of 1903 and 1905, request that a sum of £12,293, expended in cables, and £1,021, the cost of laying cables for the Aston route within the city, should be assigned to the electric lighting undertaking. Already a sum of £67,300, expended on feeder cables in connection with the tramways, has been assigned to the electricity undertaking.

The following terms have been arranged for the temporary working of the tramways in the Handsworth district:—(1) Birmingham will provide sufficient cars, for which Handsworth will pay £1 10s. per car per week as hire. (2) Handsworth Council will pay to Birmingham working expenses at the rate of 5½d. per car mile. (3) Handsworth Council will provide electrical energy, car-shed accommodation, and maintain the permanent way. (4) Birmingham will maintain overhead equipment, the cost of which is included in the working expenses of 5½d. (5) Birmingham will hand over to Handsworth all receipts from the traffic. This arrangement is subject to reconsideration immediately the outstanding questions between the Handsworth Council and the company, who have control of the Aston tramways, are settled, so that through services can be arranged.

BOLTON: *Power Supply.*—Messrs. H. Bessemer & Co., Ltd., of the Bolton Iron and Steel Works, have asked for a reduction in the charges for electricity supplied by the Corporation to their works, and if no concession is made they propose erecting their own power station.

BO'NESS: *Electricity Works Assessment.*—The National Electrical Construction Co., the owners of the electricity works at Bo'ness, appealed against the decision of the Valuation Committee of the County Council of Linlithgow, in connection with the valuation of the electricity works and mains. The Committee's valuation was £650 upon the works and £650 upon the mains, whereas the company contend that the total valuation should be £400, which was the sum at which the valuation stood for the year 1906-7. The Valuation Committee, on the other hand, consider that £400 was an arbitrary sum and was not a fair valuation of the undertaking, the capital expenditure upon which amounted to £25,946, and on account of which an annual payment of £1,650 was made to the town council. Taking into account, however, that the works had only been in existence for three years, they were willing now to fix the annual value at 3 per cent. on the cost, or £720. The Appeal Court has upheld this decision.

BRENTFORD: *Tramway Track Repair.*—At the last meeting of the District Council the Special Committee appointed to consider the condition of the tramway track reported that the repairs were being carried out in a most unsatisfactory manner by the Tramway Co.'s men, and that the present condition of the track was dangerous to traffic, due to the track being so much worn and in a bad state of repair. The Council was recommended to serve notices on the company under the Tramways Act of 1870, and the London United Tramways Act of 1898, to take up the existing wood block paving, to take out and replace with new all worn points and rails, to readjust rails where they are sunk, so as to obtain a cross fall of 1¼ in. at least on to the near side rails in every case throughout the street. In the event of the notice not being complied with within seven days, as mentioned by the Tramways Act, the Council—(which agreed to the above recommendation)—will make representations to the Board of Trade and request that authority to direct inspection by an officer, and if the default complained of is proved to his satisfaction, his report is to be adduced as evidence, and proceedings be taken against the company for legal penalties, viz., not exceeding £5 per day for every day the non-compliance continues, until the entire track has been thoroughly repaired to the satisfaction of the Council.

BRIGHTON: *Tramway Undertaking.*—At the meeting of the Brighton and Preston Ratepayers' Association, a suggestion was made, with the hope of bringing the tramway undertaking into a more flourishing position, that lighter trams should be purchased for working on the hills, it being stated that the outlay would be more than repaid by the saving of 50 per cent. in current. It was also suggested that electric motor-omnibuses should also be taken up in connection with the tramways. Councillor Ashby, a member of the Tramways Committee, assured the members of the Ratepayers' Association that if they only understood the inner working of the undertaking, they would realise the difficulty in the way of running the system successfully. A great drawback was the interference of the Council with the recommendations of the manager, a state of affairs which would not exist in the case of a company. An objection to lighter cars was the liability of accidents. With regard to electric motor omnibuses, the Council had already received applications for permission to run these, and he agreed that this permission should be allowed. During the course of the discussion, it was suggested that the tramway system could only be made to pay by placing the control in the hands of the traffic manager, who would fit the service to the public requirements, instead of having hard and fast time tables fixed by a committee.

The Southwick Electricity Works.—At the meeting of the Corporation on Thursday, Councillor Griffiths asked that the report as to the first year's working of the Southwick electricity works should be presented as soon as possible after March 31st, and in the course of a speech went into some detail concerning the finance of the undertaking. There appears to be some misunderstanding on this matter between Mr. Councillor Griffith and the Chairman of the Electricity Committee, Mr. Alderman Carden. The transfer to the Southwick works was only made in February of last year, and it is consequently impossible to give any reliable data until a year's working has been completed under the new conditions. On the previous year's working a loss of £10,233 was made, due to the necessity for having to run two stations fully staffed and under steam for about ten months out of the year in question. This entailed a very great expenditure, but was unavoidable, as the risk of shut-downs in the event of Southwick plant failing during the period of testing would otherwise have been too great. So far as can be judged from the current year's working, there is every prospect of reducing the £10,000 loss of last year to something about £2,000, and the accounts would have been on the right side this year had it not been for the exceptionally high price of coal during the last six months. The average price has increased by well over 3s. per ton for the year's working, and this represents a total sum of over £3,000. The £10,000 deficit of last year was paid out of the reserve fund, and there is still a balance of some £10,000 or £12,000 from which this year's deficit will in all probability be paid. It may be pointed out that the rates have never been called on for anything so far by the Electrical Department, and, in

Digitized by Google

fact, in past years of prosperity the undertaking has contributed no less than £14,000 to the rates, and in view of the present position it would have been very much better had this sum been kept in the reserve fund.

CANADA: *Toronto Electric Light Co.*—In connection with the purchase of electrical plant of the Toronto Electric Light Co. by the Corporation, an independent valuation has been made which sets the value of the plant to the Corporation at $4,000,000. The company intended to ask $6,000,000, but the Corporation Consulting Engineer recommends that in this event a separate plant should be erected. The basis suggested by the Corporation adviser is one year's revenue in addition to the value of the plant.

CHEADLE AND GATLEY: *Revocation of Electric Lighting Order.*—The Board of Trade have revoked the Cheadle and Gatley Electric Lighting Provisional Order, 1900.

CHISWICK: *Smoke Nuisance from Tramway Station.*—The engineer to the London United Tramways Co. has written to the Council in reply to complaints which have been made by that body with reference to the emission of black smoke from the generating station. The engineer states that the apparatus which was installed some months ago, and which it was claimed would entirely prevent the emission of smoke, had been a complete failure, and was about to be removed from the power station. It appeared to be impossible to operate the company's station without the emission at times of a quantity of light smoke. Every precaution, however, was taken to reduce this to a minimum, and, in his opinion, there was not a chimney-shaft in London dealing with so much boiler capacity which was more free of smoke than the company's. It was stated by the Chairman of the Council that the Sanitary Inspector was dealing with the matter.

CLECKHEATON: *Proposed Abandonment of Tramways.*—With reference to the proposal of the Yorkshire (Woollen) District Electric Tramway Co. to abandon certain authorised tramways, the company has written to the Board of Trade offering to assign their powers to the local authority for a purely nominal consideration, and stating their willingness to enter into an agreement to work the tramways. The company takes this position for the reason that the local authorities of Cleckheaton and Liversidge are of opinion that the tramways would be profitable. The company further states that as the lines already constructed only yield on the average a return of 2 per cent. per annum on the capital outlay, they consider they would be ill-advised in raising further capital for the construction of the lines above referred to. At the meeting of the local Chamber of Commerce on Thursday, it was decided to again protest against the company being allowed to abandon this part of their original scheme.

New Telephone Charges.—At the meeting of the Chamber of Commerce on Thursday, it was decided to ask Sir T. P. Whittaker, the Member for the division, to do his utmost towards securing the appointment of a Select Committee to inquire into the question of telephone work and charges.

DOUGLAS (ISLE OF MAN): *Electricity Supply.*—A proposal has been before the Town Council to engage a consulting engineer to report upon the cost and feasibility of utilising water from the reservoir in connection with the generation of electricity for lighting the town and working the tramways. Rough estimates go to show that the conversion of the trams on the Douglas Promenade and in the upper town would cost between £70,000 and £80,000. At present there is a profit of £6,000 per annum made upon the existing trams, and the Council hesitate to face the risk of reducing three-fourths of the present system, which cost £59,000, to the scrap heap. Consequently it has been decided not to go further with the scheme, but to leave it open for private enterprise.

DUNDEE: *Electrical Contractors' Dinner.*—The annual dinner of the Dundee branch of the Electrical Contractors' Association, was held on the 19th inst.

DUNFERMLINE: *Electricity Supply.*—Following upon the decision of the Town Council to appoint an engineer to submit estimates as to the cost of erecting a generating station, and alternatively of taking a supply of electrical energy in bulk from the Fife Electric Power Co., Sir Alexander Kennedy has been appointed to do this.

EAST HAM: *Arc Lamp Hiring Scheme.*—The Borough Electrical Engineer is to circulate a pamphlet in connection with the hire of arc lamps at an inclusive charge per quarter, together with a draft form of application and agreement to be entered into by consumers who wish to avail themselves of an installation under this system.

EDINBURGH: *Electric Pressure Testing.*—It has been decided to instal an apparatus for testing electrical pressure in the City Chambers, and that the apparatus be placed under the direction of the gas inspector, who already has similar powers of control in relation to the gas supply.

FARNHAM: *Overhead Wires.*—A special meeting of the Urban District Council was held last week to further discuss the application of the Farnham and District Electric Supply Co. to be allowed to adopt overhead wires as part of their scheme for supplying electricity in the district. Inquiries have been made of a number of other places similarly situated to Farnham, and extracts from the return show that at Burgess Hill no complaint has been made with regard to overhead wires; Felixstowe and Walton are quite satisfied, provided light steel poles are used; the Chelmsford Borough Surveyor states that all lines should be underground, and Walton-on-Naze has agreed to overhead wires to facilitate the operation of the company. At the end of the discussion, a resolution was moved suggesting that the company might endeavour to evolve a scheme to carry the wire at the backs of houses instead of on poles in the public streets. An amendment to this was moved, giving the consent of the Council to use all overhead wires provided the poles be placed at the backs of houses. The amendment was carried by five votes to four.

HANDSWORTH: *The Tramway Question.*—At the last meeting of the District Council, it was reported that the chairman of the Council and the chairman of the Tramways Committee had at last been able to interview Mr. Emile Garcke and the secretary of the Tramways Company in London, with reference to the Handsworth tramways. As a result, a letter from the secretary of the company had been received, expressing the company's willingness to enter into negotiations with Handsworth for the sale of their section of the cable tramways, if Birmingham will join Handsworth in the matter. A suggestion was made that the price should be fixed by arbitration if they could not agree, leaving it to the respective local authorities to settle their liabilities between themselves.

HANLEY: *"Free" Wiring.*—Mr. C. H. Yeaman has presented a report dealing with the question of how far it would be possible to extend the efforts now being made to encourage the use of electric lighting in small houses and cottages. He states that most schemes of this sort have been worked in conjunction with a hire-purchase or deferred-payment wiring scheme. From inquiries made, he has ascertained that, out of 200 electrical undertakings, 162 have not entered upon any such scheme, 12 have tried and abandoned it, and only 26, of which Hanley is one, continue to work a system of deferred payment in connection with electric wiring. Of the 26 undertakings providing wiring, four did the work themselves, six handed it over entirely to private firms, and 16 employed a contractor under their own management. After very carefully investigating the evidence he has been able to collect, Mr. Yeaman has come to the conclusion that little more can be done in Hanley than has been done up to the present.

HEANOR: *Electric Lighting Scheme.*—An electric lighting scheme is under consideration by the Town Council.

HESTON & ISLEWORTH: *Refuse Destructor.*—It has been decided to place the management of all matters relating to the refuse destructor under the Electric Lighting Committee.

HUDDERSFIELD: *Electricity Accounts.*—The gross receipts of the electricity undertaking for the past year were £30,555, whilst the expenditure amounted to £19,569. After meeting capital charges, there remains a balance of £985, which has been placed to depreciation and contingencies fund. This latter fund now stands at £11,874.

IPSWICH: *Free Wiring.*—The Electricity Department is now prepared to instal wiring, lamps, and plain fittings, upon the basis of a quarterly rental per lamp installed. The consumer is asked to sign an agreement undertaking to pay the rental for at least three years, should he occupy the house for that period. The whole installation will remain the property of the Corporation, and the consumer will be required to get his landlord's signature to an agreement confirming this. The consumer may, at any time, arrange to purchase the installation for cash, or by paying an increased rental for a period. The supply will be measured through a meter in the usual way, and charged at 4d. per unit, with a discount of 5 per cent. for prompt payment. If desired, a prepayment or slot meter can be installed, ½d. per unit extra being charged in lieu of meter rent.

KINGSTOWN (DUBLIN): *Condition of Tramway Track.*—At the meeting of the Council last week, a resolution was proposed that, as the tramway company had failed to fulfil its statutory obligation to keep the tramway track in Kingstown in a safe condition, the District Surveyor be authorised to rail off for public traffic such parts of the tram road referred to. After some discussion it was decided that the Surveyor be instructed to make out a list of the dangerous places, and to forward it to the tramway company, with a request that they should at once be put in order.

LONDON: *London County Council: Electric Light Loan.*—At the meeting of the L.C.C. on Tuesday, the Woolwich Borough Council applied for sanction to borrow £5,000 to cover expenditure (£1,762) incurred up to September 30th, 1907, and to be incurred, in the purchase of electrical apparatus for letting on hire and for wiring consumers' premises on the hire-rental system. The amount applied for is made up as follows:—Arc lamps, £1,000; motors, £1,150; radiators, £350, and wiring work, £500.

Tramway Matters.—On the recommendation of the Highways Committee the Council decided, in connection with the electrification of the Beresford Square to Abbey Wood tramways, to purchase 150 yards of tramway in High Street, Plumstead, from the Bexley Urban District Council. The price, fixed at the cost of construction, less depreciation, is £1,169 15s. 9d. Certain

Digitized by Google

modifications will be required in the track work of the purchased tramway in order that through running may be arranged.

MR. Sharp asked the Chairman of the Highways Committee what progress was being made with the construction of the tramway from Hammersmith to Harlesden, and whether it would be opened in time for the Franco-British Exhibition. Mr. Whitaker Thompson replied that difficulties have arisen with Hammersmith Borough Council in regard to paving works, and the dispute might have to be taken to the Board of Trade for arbitration. These delays might prevent the completion of the whole of the route before the Exhibition, but the Council had the permission of the Board of Trade to complete the tramway as far as Uxbridge Road, and that would be done as soon as possible, but the rapidity of completion of the portion north of Uxbridge Road must depend on the reasonableness of Hammersmith Borough Council.

Camberwell: London Power Bills.—From March 31st, 1900, up to the present time, the sum of £1,568 has been spent in opposing electric power bills.

Finsbury: Tramway Speed.—The Borough Council have decided to ask the Board of Trade to restrict the speed to twelve miles an hour upon the L.C.C. tramways along Goswell Road.

Hammersmith: Reserve Fund.—In June, 1903, the Borough Council resolved to provide a reserve fund in connection with the electric light undertaking, and at that time the sum of £2,500 was carried to the credit of the fund. Nothing has since been added, but £7,000 has been transferred from the funds of the undertaking to the relief of the rates. At the last meeting of the Council, the Finance Committee reported that it was most desirable that the reserve fund should be placed on a more satisfactory basis before any further contributions in aid of the rates were made. The Council adopted the committee's recommendation that the further sum of £2,500, being part of the accumulated surplus of £5,500 not yet appropriated, be carried to the credit of the reserve fund.

Islington: London Power Bills.—Mr. Vorley, chairman of the Lighting Committee, reported to the Council last week having attended an important conference between the Law and Parliamentary Committee of the L.C.C., and representatives of Borough Councils possessing electricity undertakings. Unanimously the Borough Council representatives said that the Electricity Supply Bills ought to be opposed in Parliament. Resulting from the meeting an informal conference was afterwards held of the same Borough Council representatives, and some important resolutions were passed; so important were they that he had every confidence that they would affect the whole question of bulk supply in London in the future. Before he mentioned the matters publicly, however, he desired to bring the resolutions before the Lighting Committee, and no doubt a full report would be presented to the Council. By 18 votes to 3 the Council agreed to a resolution empowering the Lighting Committee, should they deem it desirable to modify the scale of charges to large consumers of electricity possessing high load factors, provided always that such modification apply to all consumers taking current under the same conditions, and that every such modification be reported to the Finance Committee for their sanction.

LUTON: *Opening of Tramway System.*—The system of electric tramways which have been constructed by Messrs. J. G. White & Co. were opened on Friday. The contractors some time ago submitted a proposal, which was accepted, to construct, equip, and lease the tramways for a period of years, the Corporation to provide the capital, which amounted to £62,000, and the company to pay rent equivalent to interest and sinking fund charges during the term of the lease. The system adopted is overhead trolley, and the distance at present covered is about six miles. Already there are thoughts of extending the system and linking up with the neighbouring town of Dunstable.

MANCHESTER: *Progress of Tramways.*—In an address by Alderman E. R. Wilson at the Longsight Public Hall, on Thursday, it was stated that the capital expenditure upon the Corporation tramway system now amounts to £1,750,000. Last year no less than 145,264,000 passengers were carried, 69 per cent. of whom paid a fare of one penny. The average fare received was 1·19d., and, whereas the old tramway company paid £8,000 in rates, the Tramways Committee now pays £25,000 per annum. The average cost per mile of track has been £5,270, with an additional £1,090 per mile for overhead equipment.

STOCKTON (RURAL): *Revocation of Electric Lighting Order.*—The Board of Trade have revoked the Stockton (Rural) Electric Lighting Order, 1902.

TAUNTON: *Electric Tramway Agreement.*—The Taunton Electric Traction Company has made an application for a renewal of the agreement which expires in August, under which the British Electric Traction Co. guarantees to the Corporation a minimum payment for the supply of electricity in connection with the tramways. The company intimates that if satisfactory terms can be arranged, including a reduction in the price paid for current, the extension of the trams to Rowbarton will be put in hand. The question of negotiating with the company is in the hands of the Electric Tramway Committee, and a report will be presented at the meeting in March.

YORK: *Light Railway Inquiry.*—The Light Railway Commissioners heard an application on Tuesday by the Corporation for powers under the Light Railway Act to convert the existing horse tramways to electric traction, and for the construction of additional lines. Mr. Tyldesley Jones, who represented the Corporation, said that there was a difference of opinion, both on the Council and in the city, as to whether the Corporation should work the lines themselves or lease them to a company or some other firm. A pledge was therefore given that before any decision should be come to on that point the ratepayers should be consulted, and a special clause had been introduced into the Order to enable the ratepayers to vote as to three alternatives:—(*a*) Shall the light railways be constructed and worked by the Corporation? (*b*) Shall the light railways be constructed by the Corporation and then leased to a company, firm, or person to work them? (*c*) Shall the undertaking be leased to a company to construct and work? The cost of the tramways on the surface-contact system was estimated at £128,000, and the Corporation owned the electric lighting station, which contained quite sufficient plant to deal with these tramways. The North-Eastern Railway Co. contended that certain bridges should be rebuilt, but after hearing the evidence the Commissioners decided to grant the application, and expressed the opinion that the bridges were safeguarded in the order.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ACCRINGTON.—New baths, with electrical installation, are to be erected at Accrington at a cost of £9,500.

ACTON.—Tenders are invited for the annual supply of meters, prepayment meters, carbons, house fuse-boxes, meter boards, and cables. Particulars from Mr. J. M. Blair, the Electrical Engineer, 130 Churchfield Road, Acton, and tenders to the Clerk by February 29th.

AUSTRALIA.—The Commonwealth Government calls for tenders by April 14th for the construction and laying of two cables between Victoria and Tasmania. £1,000 deposit is required, and full particulars and specifications may be inspected at the Commonwealth Government office, 72 Victoria Street, Westminster.

BELFAST.—Extensions of cables have been authorised at a cost of about £250 in connection with the Campbell College.

BRADFORD.—The Tramways Committee has decided to spend £21,000 on the renewal of the track in various parts of the city.

BURY.—The Corporation invite tenders for the supply, delivery, and erection of two 2,000-kw. turbo-alternators with exciters and condensers. Specifications and general conditions may be obtained from Mr. S. J. Watson, Electricity Works, Bury (fee £2 2s., returnable), and tenders to the Town Clerk by March 16th.

DUNDEE.—Tenders are invited for E.H.T. three-phase and direct-current switchboards and substation generating machinery. Full particulars from Mr. H. Richardson, the Chief Electrical Engineer (fee £3 3s., returnable), and tenders to the Clerk by March 2nd.

FINCHLEY.—The Council invites tenders for the supply and erection of one 700-kw. high-speed engine and dynamo combined. Specifications, &c., from the Electrical Engineer, Mr. E. Calvert, Electricity Works, Squire's Lane, Finchley, N. (Fee, £2 2s., returnable.) Tenders to the Town Clerk by March 2nd.

GLASGOW.—The Tramways Department invite tenders for the supply and erection of two movable bridges over the Forth and Clyde Canal at Dalmuir and Kilbowie. Full particulars from the General Manager, 46 Bath Street, Glasgow, and tenders to the Town Clerk by April 15th.

HANDSWORTH.—Tenders are invited for (*a*): 315 kw. generating set, (*b*) feed-pump economiser and pipe work, (*c*) switchgear for 315 kw. generating set. Full particulars from Messrs. Kennedy & Jenkin, 17 Victoria Street, fee £3 3s., returnable, and tenders to the Town Clerk by March 4th.

HANLEY.—On the 18th inst., Mr. H. R. Hooper held a Local Government Board inquiry into the application of the Corporation to borrow £18,000 for electricity extensions. Included in this were a new 500 kw. steam generator, £5,000; mains, transformers, meters, instruments, and tools, including overdraft mains at December, 1904, and expenditure under all these heads to December, 1906, amounting to £5,358; and future extensions from that date of £12,642. Owing to the new requirements of the Local Government Board, that the expenditure under each head should be given separately and in detail, the Inspector was furnished with full particulars of the expenditure from the commencement, and he decided to deal with the application as at the 12th inst., at which date the expenditure in excess of previous sanctions amounted to £9,431, while to avoid the necessity for a further sanction at an early date he

Digitized by Google

also allowed prospective sums to be included for new plant, £5,000; new mains, £4,000; new transformers and substations, £3,000; and instruments, boosters, &c., of £538; making a total of £21,969, or nearly £4,000 on suspense account for the next two years, beyond the amount applied for. The Inspector emphasised the point made in several recent inquiries that meters and testing instruments, having short life, should be provided out of revenue. Also that independent ledger accounts must be kept of the expenditure against each sanction, and the Electrical Engineer gave such particulars for the period since he took office in the spring of 1905. The Electrical Engineer pointed out that while he entirely agreed with the principle of paying out of revenue for all small items, these made a large annual sum in the aggregate, and an undertaking adopting this virtuous policy suffered in its cost sheet in comparison with one not doing so, unless such charges were made upon a depreciation and reserve fund into which surplus balances or profits were paid annually.

HASLINGDEN.—At a meeting of the Haslingden Town Council on February 20th, it was reported that the Local Government Board had sanctioned a loan of £8,400 for the erection of a refuse destructor at Lincoln Place, which will be worked in connection with the electricity undertaking.

HEYWOOD.—The report by the Electricity Committee with regard to extensions at the electricity works, involving an expenditure of £10,000, has been approved.

HORNSEY.—The Finance Committee recommend the adoption of the recommendation by the Electricity Committee that a new feeder for the supply of electricity to the Muswell Hill district should be laid, and that application be made to the Local Government Board in this connection with regard to a loan of £10,000.

ILFORD.—The Council invites tenders for the supply of the following, required during the year ending March 31st, 1909, for the electricity department:—Meters, cables, incandescent lamps (carbon and metallic filament), arc lamp carbons, house service fuse boxes, joint boxes, coal. Full particulars from Mr. A. H. Shaw, Electricity Works, Ley Street, Ilford, Essex, and tenders to the Clerk by March 10th.

LEEK.—The resident engineer is to undertake the duties of consulting engineer in connection with the proposed extensions at the electricity works.

LLANDUDNO.—The Council has authorised the extension of the plant at the generating station, which has been rendered necessary in connection with the supply of electrical energy to the tramways.

LONDON: *London County Council.*—Tenders are invited for the supply and delivery of about 525 tons of steel girder tramway track rails and fastenings required for the reconstruction on the overhead trolley system of electric traction, of the existing tramways from Brixton Road to near Camberwell Green. A statement must be made as to where the rails will be manufactured. Specifications, &c. (fee, two guineas, returnable), from the Chief Engineer to the Council, and tenders to the Clerk by March 3rd.

MANCHESTER.—The Electricity Committee invites tenders for the supply, delivery, and erection at the Stuart Street station of natural draught cooling towers. Particulars from Mr. F. E. Hughes, secretary to the electricity department, Town Hall (fee, two guineas, returnable), and tenders to the chairman of the Electricity Committee by March 10th.

RICHMOND (*Ireland*).—A sub-committee of the Richmond Asylum has been appointed to consider the installation of electric light.

ROCHDALE.—Major Stewart, R.E., on Tuesday held a Local Government Board inquiry into an application by the Corporation for sanction to borrow £22,175 for the purposes of electric lighting. It was explained that in the first few years there was a loss of £5,543 on the electricity undertaking, which had to be paid for out of the rates, but £5,350 of this was repaid, and there was now a reserve fund of £4,000. The net profit had increased from £1,195 in March, 1905, to £4,135 last year. The Inspector expressed satisfaction with the accounts.

SPAIN.—The *Gaceta de Madrid* of February 7th notifies that the Compañia del Ferrocarril de Sarriá á Barcelona have applied for a concession for an electric tramway in Barcelona, and that a period of one month from the date of publication has been appointed for the presentation of more favourable proposals.

The *Gaceta* of February 11th notifies the approval of the transfer of an electric tramway concession granted to the Seville Tramways Co., Ltd., to the Compañia Sevillana de Electricidad.

The *Gaceta* of February 11th also announces that tenders will be opened at noon on March 16th, at the Junta de Obras del puerto de la Coruña, for the supply of three three-ton electric cranes, at a maximum cost of 133,919 pesetas (about £4,618). Local representation is necessary.

WREXHAM.—Tenders are invited for stores. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by March 6th.

WEST HAM.—With regard to the estimate of the cost of plant required for the Council's electricity undertaking up to March 31st, 1910, the consideration of which stands adjourned pending the decision of the Finance Committee of the Council on the question of applying to the Local Government Board for sanction to a loan for the sums of £7,045 and £64,880, a further report has been made by the Electrical Engineer giving an explanation of the necessity for the new plant, and also particulars as to the periods during which the amounts will be required. It is estimated that for the year ending March 31st next £12,300 will be wanted for generation, and £4,500 for distribution. For the year to end March 31st, 1909, £18,005 is put down for generation, and £9,750 for distribution, and for the following year £6,325 for generation, and £14,000 for distribution. The Electric Lighting and Tramways Committee have approved this allocation of the estimated cost, and have instructed the Electrical Engineer to submit the same to the Finance Committee.

WIGAN.—Tenders are to be invited by the Board of Guardians for an electrical installation at the new Workhouse Infirmary, Billinge.

TENDERS RECEIVED AND ACCEPTED

BELFAST.—Quotations have been received for scrap copper and wire, and the tender of Messrs. Pearce, Brown, Smith & Co., 7 Wilson Street, Finsbury, London, has been accepted.

BIRMINGHAM.—An order has been placed with Messrs. Dick, Kerr & Co. for 30 electric tramcars, similar to those already in use.

BIRMINGHAM.—The Birmingham Tame & Rea Drainage Board have accepted the tender of Messrs. Johnson & Phillips, Ltd., for the complete erection and equipment of a 6,600-volt transmission line in connection with the new storm water pumping plant which is being installed.

CHISWICK.—The Council has accepted the tender of E. Evans, Hounslow, for the annual maintenance of fire-alarms and telephones in the Council's offices.

KIRKCALDY.—The tender of Mr. R. Bryson, of Kirkcaldy, has been accepted for wiring the new sanatorium at £29 15s.

LEEK.—An agreement has been entered into with the D.P. Battery Co. to put the batteries at the generating station into good order and maintain them for ten years at a premium of £65 8s. per annum. An offer by the Vulcan Boiler & General Insurance Co. for insurance of the engines and dynamos at £52 3s. has also been accepted.

LOCHGELLY.—The Lochgelly Coal & Iron Co. have placed an order with Messrs. Johnson & Phillips, Ltd., for the complete erection of a 3,000-volt overhead transmission line for their Lochgelly works.

LONDON: *London County Council.*—The tender of P. & W. Maclellan, Ltd., amounting to £1,072 18s. 9d., for the supply of 136 tons of flat-bottomed rails, &c., required for the tramway car-sheds at Bow, Hammersmith, and Hackney, has been extended to include about 115 tons of two kinds of flat-bottomed rails with bolts and fish-plates, for the first portion of the central car repair depôt in Woolwich Road. For the rails the price quoted is 2s. 6d., less than the original figure of £7 8s. 9d. per ton. The total cost of the 115 tons is estimated at £956.

The tender of the Electric Construction Co., Ltd., for the supply of 500 kw. machines is to be extended to include a 150 kw. machine required for starting the larger machines, now being installed at Hammersmith temporary substation. The price of the machine is £541 10s.

The Council has accepted the tender of the India Rubber, Gutta Percha, & Telegraph Works Co., Ltd., for the supply of 300 plough bases at 54s. each, and 600 leads at 4s. each, required in the tramways department.

The Council have accepted the tender of Messrs. Johnson & Phillips, Ltd., for supplying and laying cables in connection with the extension of tramways in Seven Sisters and Caledonian Roads.

Lambeth.—The Borough Council has accepted the tender of the General Electric Co. at £3 2s. 8d., for the supply of additional electric light fittings for the new Town Hall.

Stepney.—An order has been placed with the Tudor Accumulator Co., Ltd., for a battery of nine cells (in connection with the meter testing switchboard at the generating station) at £64.

MUMBLES.—Mr. A. H. Gibbings, of Liverpool, has offered to undertake to convert the present 200 public lamps from gas to electricity at a cost varying from a minimum of £2 15s. to £3 10s. per lamp per annum, according to the number of hours of lighting. The present cost of public lighting is about £2 3s. per lamp. During the discussion which took place upon this offer, it was stated that some time ago Mr. Gibbings had told the Council that electric light would prove cheaper than gas, but from this offer it appeared that it would cost about £150 per annum more than they paid for gas. In reply to this, it

Digitized by Google

was pointed out that there would be considerably more light. It was decided, however, to inquire of Mr. Gibbings if he could give better terms.

WEST HAM.—The Electric Lighting and Tramways Committee has accepted the offer of the Bell Punch and Printing Co., Ltd., to extend the contract for ticket punches for a period of three years, at the rate of 12s. per punch per annum, instead of 15s., as per the present contract. This will effect an annual saving of about £52 10s. The Committee has approved the acceptance of the offer of the present contractors, the Cryselco Co., for the annual supply of carbon lamps at present contract prices, less 10 per cent., and also the purchase from Wm. Cory & Sons, Ltd., of 12,000 tons of North Country coal at 10s. (a considerably more favourable price, points out the Engineer, than obtained during the past year), and 12,000 tons at 9s. 8d., of North Country coal, slightly lower calorific value accounting for the difference in price.

WILLESDEN.—The Urban District Council has accepted the tender of G. & H. Turner for the annual maintenance of the telephone system.

COMPANIES' MEETINGS AND REPORTS

ABERDEEN SUBURBAN TRAMWAYS.—The accounts for the half-year ended January 31st, 1908, show a profit of £887, making, with the sum brought forward, a balance of £1,587 at the credit of profit and loss account.

BRUCE PEEBLES.—An extraordinary general meeting was held in Edinburgh on Monday to consider a resolution for the voluntary winding up of the company. Mr. W. Peebles, who presided, said that the conditions which had led to the present crisis were: (1) the need of further working capital, accompanied by extreme stringencies of the money market. (2) The stoppage of practically all new contract work for this reason. (3) High price of raw materials. (4) The low prices obtained through undue competition. When the company was formed the prices obtainable for its ordinary manufactures were nearly double those of to-day, but there had been a constant decline brought about, first by various competition, and latterly by the continued competition of home firms. With regard to the Moscow tramway contract, option had been obtained which it was hoped would be of benefit. The chairman impressed upon the shareholders that the business was a valuable one, and that if they agreed to a scheme of reconstruction the company might emerge from the crisis stronger than ever. The combined holding of his family in the company was £78,000. A resolution requesting the joint liquidator to consider whether a scheme of reconstruction was feasible was carried.

Mr. A. W. Tait, one of the liquidators, has prepared a statement in regard to the financial position of the company, giving comparative figures for 1906 and 1907. Dealing first with the assets, the buildings and works at East Pilton are stated for 1907 at £49,000, and for 1906 at £49,647. The other assets are:—Working plant, machinery, tools, office furniture, trade marks, patent rights, &c., £104,248, as against £110,091 (in the 1907 figures the amount of goodwill was about £23,000); stock, stores, work in progress, and finished work, £82,565, as against £109,593; book debts, £123,669, as against £301,572; cash in hand and bank, £3,124, as against £2,886; shares in power and traction companies, £115,777, as against £51,920; and special reserve fund investments, £11,937, as against £7,718. The liabilities were—Preference share capital, £150,000 as against £150,000; ordinary share capital, £141,905 as against £141,905; debentures, together with interest accrued, £75,890 as against £75,890; debts due by the company, £183,909 as against £208,907. There is an addition this year of overdraft on the Royal Bank at December 31st of £32,589, and there is a reserve account—special reserve £11,556, and general reserve £27,000. The net loss after making provision for the clearing up of the contracts still on hand carried into this balance-sheet was £151,228, and if deducting the general reserve fund and special reserve fund there was a loss of £92,671.

A committee of shareholders has been appointed to confer with the liquidators.

An application has been made in the Edinburgh Court of Session on behalf of Mr. C. J. Shields, a preference shareholder, objecting to the appointment of Mr. A. W. Tait as official liquidator, on the grounds that he is not subject to the jurisdiction of the Court, that it is inexpedient that a director should be appointed liquidator, and that the expense attendant on the appointment of a London accountant is undesirable in the interests of economy.

BUENOS AIRES & BELGRANO ELECTRIC TRAMWAYS.—At the annual meeting on Thursday, Mr. J. B. Concanon, the Chairman of the company, who presided, stated that the accounts comprised the working for the six months to June 30th, 1907, as well as the half-yearly instalment received in accordance with the agreement for the sale of the property. The actual net profits for the six months to June 30th, after deducting London office expenses, amounted to £32,668, and in view of the sale, this sum was higher than it would have been, as no provision had had to be made for depreciation and renewals. The report and accounts were adopted. Dealing with a complaint as to there being no dividend declared upon the ordinary shares, the chairman stated that it was not proposed to pay this dividend owing to the fact that before it could be made, an application to the Courts for a reduction of capital would be necessary. This would involve expense, but even if this were deducted, the directors hope to make a very large distribution to the ordinary shareholders.

CHARING CROSS, WEST END & CITY ELECTRICITY SUPPLY: *West End Undertaking.*—The report shows gross earnings for the year ended December 31st, 1907, amounting to £151,920, compared with £126,145, and expenses, including depreciation, £80,114, compared with £84,088. After bringing in the balance of £4,574 from last year, and paying interest on the debenture stock, there is a balance of £42,023, out of which the dividend for the year on the preference shares, and an interim dividend for the first half-year at the rate of 5 per cent. per annum on the ordinary shares has been paid, amounting to £28,000, leaving a balance to be dealt with of £14,023. The directors propose a final dividend for the second half-year at the rate of 5 per cent. per annum, making 5 per cent. for the whole year, absorbing £10,000, and to carry forward £4,023. The company has now connected to its West End mains the total equivalent of 538,964 8-c.p. (or 30 watt) lamps, which is an increase of 28,375 upon last year's figures. The total is made up as follows:—391,201 in lighting, 10,238 in heating, and 137,525 (5,501 h.p.—4,129 kilowatts) in motors.

City Undertaking.—The gross earnings of this undertaking were £118,543, compared with £105,502, the expenses being £63,748, compared with £57,324. Interest on debenture bonds and loans, and dividend on preference shares absorbed £48,133. From this is deducted the deficiency on preference shares' dividend, 1902-1905, £4,406, leaving £2,256. The City undertaking has, therefore, been able out of its revenue for the year 1907 to pay the interest on its debenture bonds and dividend on its preference shares, to repay the balance of £4,406 to the West End undertakings, and to carry forward the sum of £2,256 2s. 3d. The company has now connected to its City mains the total equivalent of 454,757 8-c.p. (or 30 watt) lamps, which is an increase of 42,073 upon last year's figures. The total includes 287,787 in lighting, 26,770 in heating, and 140,200 (5,608 h.p.—4,209 kilowatts) in motors.

The report further states that no progress was made in the last session of Parliament towards settling the question of the bulk supply of power in the metropolitan area. The question has again been carefully considered by the Board, in conjunction with the Boards of other electric lighting companies, and they are still of opinion that the most practical way of dealing with the question is to entrust the bulk supply to an undertaking composed either of all or some of the London electric supply companies. With this end in view a Bill is being promoted in the present session of Parliament to constitute a joint committee representing eight of the London electric supply companies. The chief object of this joint committee will be the rendering of mutual assistance and the giving of a supply of energy in bulk. A special resolution approving this Bill will be submitted at an extraordinary general meeting of the shareholders to be held immediately after the annual meeting on March 3rd.

CHELSEA ELECTRICITY SUPPLY.—The report for the year ended December 31st, 1907, shows a profit of £33,099, which with £1,092 brought forward and £451 balance of interest, makes a total of £34,642. After deducting interest on debenture stock, interim dividend of 6 per cent. on preference shares, and interim dividend on ordinary shares at the rate of 4 per cent. per annum, there remains a balance of £20,924, which the directors recommend shall be appropriated as follows:—Renewals and depreciation fund, £11,619; debenture stock premium redemption fund, £519; amount written off cost of extinction of founders' shares, £802; final dividend on the 6 per cent. preference shares, £900; final dividend on the ordinary shares at the rate of 5 per cent. per annum, making 4½ per cent. for the year, £6,179; leaving a balance to be carried to the next account of £904. The number of 8 c.p. lamp equivalents connected on December 31st, 1907, was 240,735, an addition of 7,430 during the year, and the total number of units sold was 3,548,628, being 240,914 more than the previous year. At the close of the meeting on March 11th a special meeting will be held for the purpose of confirming the promotion of the London Electric Supply (Joint Committee) Bill in Parliament.

GROSSE BERLINER STRASSENBAHN.—The report for the year 1907 shows a net profit of £490,000, which allows of a dividend of 8 per cent. on the capital of £5,000,000. The unfavourable effect of the cold winter of 1906-7, and the following wet spring and summer months, had been offset by the very favourable conditions during the autumn months. Owing to the increased cost of material, the maintenance expenses had increased. The net receipts per car-mile had been 8·1 pence.

Digitized by Google

the same as the previous year. The total number of car-miles had increased from 51·5 million in 1906 to 53·2 million in 1907, the number of passengers carried from 364 million to 378 million, and the receipts from £1,700,000 to £1,770,000. The working expenses were for the past year 55·3 per cent. of the receipts, against 53·9 per cent. for the previous year. The cost of the energy supplied was 22·5 per cent. of the total working expenses, amounting to some £214,000. The company now owns some 325 miles of single track, and 2,494 cars. The number of employees amounts to 10,400. Of the smaller companies, the West Berlin suburban tramways shows a net profit of £45,000, and pays a dividend of 5½ per cent. The Berlin-Charlottenburg tramways show no net profit.

LANARKSHIRE TRAMWAYS.—The result of the December half-year's working show revenue amounting to £34,929 and expenses to £20,732. Deducting interest on debentures, interest on loans, contributions payable to local authorities, and amounts written off, a total of £4,124, there remains £10,070, and adding balance brought forward from the last accounts, viz., £5,182, the sum of £15,252 is available for distribution; £5,500 has been placed to reserve for depreciation; a dividend is recommended at the rate of 6 per cent. per annum on the issued share capital for the half-year; £240 is absorbed in directors' fees; and £895 is carried forward. Part of the original single line in Clyde Street has been taken up and double track substituted, the cost of the original line being written off in the attached accounts. During the half-year £5,000 has been paid off the loan from the company's bankers. The time allowed for the construction of the extensions authorised by the company's order of 1903 expires next August, and application is now being made to Parliament to extend the time for a further period. The directors, however, propose to proceed at once with the construction of two short extensions, one to the Hamilton Burgh boundary in the Bothwell Road, and the other from Motherwell Cross to the Motherwell Burgh boundary beyond Coursington Bridge. To meet the immediate requirements for capital expenditure for these extensions and seven additional cars, the shareholders are now invited to subscribe for £20,770 additional share capital at par, which is the balance the company is now authorised to issue without further sanction from the shareholders. The shareholders will be asked at an extraordinary general meeting, to be held immediately before the general meeting on the 20th inst. to grant authority to issue the remaining share capital authorised by the company's order of 1903 as and when required.

At the meeting on Thursday, the report and accounts were adopted. Mr. A. R. Monks, who presided, stated that the Cambuslang extension of 3¼ miles which had been opened during the year, and which had been linked up with the Glasgow tramways, had fully realised expectations.

LANCASHIRE UNITED TRAMWAYS.—The accounts for the year 1907 show a profit of £12,789, and there is a balance of £289 after payment of the prior lien debenture stock interest.

MATHER & PLATT.—The report to December 31st last shows a net profit for the year, after charging depreciation and making provision for directors' remuneration and expenses, of £125,677, to which is added the balance brought forward from last year, viz., £15,380, showing an available total of £141,057. The preference dividend, and the interim dividend on the ordinary shares paid on September 1st last, for the half-year to June 30th, 1907, absorbed £22,000, leaving for disposal £119,057. The directors recommend a dividend of 5 per cent. per annum on the preference shares for the half-year to December 31st last; a dividend at the rate of 10 per cent. per annum on the ordinary shares for the year to December 31st last (less interim dividend paid in September); a bonus of 5 per cent. on the ordinary shares; transfer of £40,000 to reserve account (bringing up the amount to £340,000); transfer to "Employees' Benefit Fund" of £5,000, carrying forward £16,057. The meeting will be held in Manchester to-day.

NATIONAL ELECTRIC SUPPLY.—The annual general meeting was held at Preston last week, Mr. J. Booth presiding. The sum of £3,745 has been expended upon capital account during the year ended December 31st, 1907, principally in mains and additions to the pumping plant at the station. The receipts have increased by £1,650, the company having sold £104,000 units more during the year than during the previous year. The net revenue account shows an increase of £1,200, and a dividend has been declared upon the ordinary shares of 8s. per share. £600 have been added to the reserve and depreciation account, and the remainder is carried forward. In the course of a few remarks upon the future position of the electric supply industry in Preston, the Chairman stated that although the increasing use of metallic filament lamps might, on the surface, be against the interests of electric supply companies, he had no fears of this nature, because he thought that consumers would go in for greater illumination with the satisfaction of not having to pay more for it. The demand for electricity for power purposes was also steadily growing, and there was also a small demand for electricity for cooking and heating purposes, improved appliances for which were being put upon the market.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING.—The report for the year ended December 31st, 1907, states that the number of units sold was 9,282,370, as against 8,076,770 in 1906, an increase of 14·92 per cent. The increase has not been in proportion to the estimate which was formed in the beginning of 1907, due to the falling off in the demand for electrical energy for power and other purposes in the engineering and other trades, owing to lessened work, and this combined with the increased cost of coal has had a depreciatory effect upon the anticipated profits for the year. The gross profits for the year for Newcastle amount to £18,501, and for Newburn to £856, which, together with the sum of £9 received for transfer fees, and £2,248 brought forward from last year, makes the total £21,615. After deducting directors' and trustees' fees, income tax, &c., and making provision for leasehold redemption fund, there remains a net balance of £19,922. The directors, after providing for interest on debenture stock, &c., recommend a dividend at the rate of 4 per cent. per annum for the half-year ended December 31st (less income tax), which, together with the interim dividend paid in August last makes 4 per cent. for the year. To accomplish this it will be necessary to draw upon the reserve fund to the amount of £1,222. The directors, however, feel justified in recommending this in view of the abnormal price of coal and the other circumstances mentioned above. An arrangement has recently been made with Messrs. John Spencer & Sons, Ltd., for a term of years to utilise their exhaust steam at the Newburn station and thus energy will be produced at a very low rate, which will assist the profits of the station considerably.

NORTHALLERTON ELECTRIC LIGHT & POWER.—The result of the year's working to December 31st, 1907, is a net profit of £142, which, with the balance brought forward from last account, makes a total of £214. A dividend of 5 per cent. is recommended.

NORTHAMPTON ELECTRIC LIGHT & POWER.—The report for the year ended December 31st, 1907, shows that the equivalent of 3,222 eight c.p. lamps have been added to the lighting load, and 33 h.p. to the motor load. The number of consumers has increased by 108, and the output by 837,161 units, an increase of 11½ per cent. The maximum load on the plant during the year was 645 kw., an increase of 10½ per cent., whilst the load factor was 12·7. The report refers to the considerable increase in the cost of coal, but points out that the apparent increase in rates and taxes is due to overload between two years in respect of income tax on the bonus paid in 1906. In all other items of working costs, there has been substantial decrease in power units generated. Owing to the continued extension of business, further plant is needed, and additional capital outlay will have to be incurred during the current year. The directors propose to add £2,000 to the depreciation fund, to write £100 off motors, and to apply the balance of £1,186 in payment of a half-year's dividend of 5 per cent. on the preference shares, and 6 per cent. (making 5 per cent. for the year) upon the ordinary shares, carrying forward £162.

NORTH LONDON RAILWAY.—At the half-yearly meeting on Thursday, Lord Rathmore, the Chairman, in moving the adoption of the report, which shows a very heavy fall in receipts from passenger traffic, namely, £18,180, stated that the cause of this formidable decline was the great increase in the number and efficiency of their competitors. Electric tube railways and electric tramways were most dangerous competitors, the London County Council electric tramcars being equipped apparently regardless of expense. However convenient these luxurious conveyances might be for the persons to be carried, as ratepayers the railway companies felt they had a grievance.

NOTTING HILL ELECTRIC LIGHTING.—At the ordinary general meeting on Tuesday, Sir William Crookes presiding, the report and accounts given in our last issue were adopted. In the course of his speech the Chairman referred to the fact that the company now paid rates to an amount equal to 2½ per cent. per annum on their share capital, but the Board had been taking advice with a view to appealing against the assessment. The manner in which the assessment arrived at was actually a tax upon their goodwill. The price of coal had increased very considerably during the past half-year, and was 33 per cent. more than in the previous year. Everything pointed to increasing prosperity in the future, a very important contract having been entered into in connection with the Franco-British Exhibition, by which the Hammersmith Borough Council would take from the company not less than one million units between April and November. At the conclusion of the general meeting, a special meeting was held for approving the Bill promoted by the Kensington and Knightsbridge, Notting Hill, St. James and Pall Mall, Westminster and the Central Company, which has been deposited in Parliament to enable the companies to link up their supply, and generally assist each other. Referring to the other Bills relating to electric power in London, the Chairman stated that it was thought advisable to oppose both in order to get clauses inserted to protect their interest.

OXFORD ELECTRIC.—The report for the year ending December 31st, 1907, states that the revenue account shows a profit (including £895 brought forward from last year) of £15,848. After providing £2,000 for debenture interest and writing off £2,329 on account of hire-purchase and college installations, the balance available for dividend is £11,519. The directors recommend a dividend of 7 per cent. per annum on the ordinary shares, a 5 per cent. dividend on the preference shares, and a 5 per cent. dividend on the preference share capital issued in

Digitized by Google

1907, placing to reserve and renewal of plant account, £2,500, and carrying forward £977. It is estimated that at December 31st last there was the equivalent of over 91,000 8-c.p. lamps connected to the mains. The number of Board of Trade units sold during 1907 was 12 per cent. larger than in the previous year. A considerable portion of this increase is due to current supplied for motive power purposes. The meeting is on March 6th.

SCARBOROUGH ELECTRIC SUPPLY.—The report for 1907 shows that although there has been an increase in the amount of energy supplied during the year, the receipts have continued to be adversely affected by the depression of trade in the town, while the expenses have risen owing to the higher price of coal. The capital outlay during 1907 was £1,330, as against £3,427 for 1906, the principal item of expenditure being for extension of mains. The accounts show that after placing the sum of £750 to depreciation account there is a balance on revenue account of £4,238. The directors recommend that a dividend be paid (free of income-tax) at the rate of 4 per cent. for the year, which will absorb £3,990, leaving to be carried forward £248. The meeting will be held to-day at Scarborough.

At the meeting on Thursday, the report and accounts were adopted. The Chairman stated that the Corporation had approached the company with regard to the erection of a refuse destructor, and had asked what price they would charge per ton for this. A price for this was very difficult to arrive at, for, from their investigations, they found that it averaged from 6d. to 3s. per ton in various parts of the country. The Electric Supply Company had asked 2s. 6d. per ton, but the Corporation, although they made no offer, evidently thought this too high. At the same time, he thought it would be a pity if the Corporation went to the expense of erecting works themselves without endeavouring to come to terms with the company.

SIMPLEX CONDUITS.—The second annual general meeting of the above company was held last week at Birmingham. The chair was occupied by Mr. Henry Huggins (chairman). The profits of the year, after providing for bad and doubtful debts, amount, with interest on investments and transfer fees, to £13,894, and after charging directors' fee, depreciation, and income tax, £2,340, and adding the amount brought forward from last year £1,379, there remains for disposal £12,933. The Chairman congratulated the shareholders upon the result of the year, pointing out that after paying a dividend of 6 per cent. on the preference shares, amounting to £2,280 and 10 per cent. on the ordinary shares, absorbing £4,000, they had carried £4,000 to reserve, and £2,653 forward to next year.

SMITHFIELD MARKET ELECTRIC SUPPLY.—At the meeting on Friday, the report and accounts, given in our issue for February 15th, were adopted. Mr. H. S. Leon stated that the position of the company, so far as the Corporation of the City of London was concerned, remained unaltered, and, as stated in the report, this was the reason for the directors' hesitation in declaring any dividends for the year 1907.

YORKSHIRE ELECTRIC POWER.—Mr. A. G. Lupton presided at the half-yearly meeting on Wednesday last week, when the report and accounts, given in our issue for February 5th, page 191, were adopted. He pointed out that in the revenue account under the heading of Management and General Expenses, no amount had been charged to the item "Auditor appointed under provisions of the Act." He stated that the Board of Trade would in future probably appoint the same auditors to represent them as those now representing the shareholders, with the result that unnecessary trouble would be saved and a definite saving to the finances of the company made. The extra cost of coal shown by the balance sheet he said was largely due to the fact that the sale of current had been greater than in the preceding half-year, but also in part to the abnormal rise in the price of coal. The revenue account showed a 40 per cent. increase. One of the most significant changes which had taken place during the year was with regard to the application of electricity in the textile industry. Four years ago the use of electricity for textile purposes was so small as to be practically negligible, but to-day in their power area, there were districts where entire mills were run electrically. One great satisfactory feature was that nearly all the consumers had connected, or arranged to connect, more motors than they had originally intended. A determined effort was also being made to attract new consumers into the district, the power mains being laid in districts pre-eminently suitable for electric power factories. He was glad to say that the feeling of opposition on the part of the local authorities was largely passing away, and the revenue which the company was deriving from the supply of electricity was growing fast. During the half-year under review, agreements for 3,252 h.p. had been made, which was nearly four times the increase of the preceding six months. Terms had been arranged with the Brighouse Corporation, under which the municipal generating station was closed and power taken in bulk from the company. A considerable revenue was also hoped for from tramways in this borough. In conclusion, Mr. Lupton stated that the time of waiting for many of them had been very tedious, and the directors had had very anxious moments, but it was felt that the company was now fairly started on its way towards success, and the districts served by the company were appreciating the facilities offered them.

PARLIAMENTARY INTELLIGENCE

LONDON ELECTRIC POWER BILLS.—The London (Westminster & Kensington) Electric Supply Bill was read a second time in the House of Lords on Tuesday. The London Electric Supply Bill was read a second time in the House of Lords on Thursday.

THE SUPPLY OF ELECTRICITY BILL.—In reply to a question in the House of Commons last week Mr. Lloyd George stated that he hoped to introduce a Bill amending the Electric Lighting Acts as soon as there seemed to be a reasonable prospect of time available for its discussion.

LONDON & WINDSOR MOTOR ROADS, TRAM ROADS, & TRAMWAY BILL.—This Bill, which has been under consideration by Mr. Campion, one of the Examiners of Proofs for Private Bills, with the Standing Orders of the House of Commons for several days, has been referred to the Standing Orders Committee upon a number of points in connection with notices, &c.

PETITIONS AGAINST BILLS.—The period for lodging petitions against Bills in the House of Lords has now expired, and since our last issue 42 petitions have been deposited against the London & District Electricity Supply Bill, 28 against the London Electric Supply (Joint Committee) Bill, 17 against the London & Windsor Motor Roads Bill, 13 against the West London, Barnes & Richmond Tramways Bill, whilst several petitions have been presented against the Highgate Hill Tramways Bill, London County Council Tramways Bill, London (Westminster & Kensington) Electricity Supply Co.'s Bill, and the Croydon & Southern District Tramways.

PROGRESS OF ELECTRIC BILLS.—The Metropolitan District Railway Bill and the Great Northern, Piccadilly & Brompton Railway Bill were read a second time in the House of Lords on Thursday. The South Wales Electric Power Distribution Co.'s Bill was read a second time in the House of Lords on Wednesday last week.

STANDING ORDERS COMPLIANCES.—The West London, Barnes & Richmond Tramways Bill has been referred to the Standing Orders Committee, owing to the promoters being unable to secure the consents of the London County Council, Surrey County Council, Hammersmith Borough Council, Wandsworth Borough Council, and the Barnes Urban District Council. The Croydon & Southern District Tramways Bill has been referred to the Standing Orders Committee owing to the consent of the Croydon Corporation and the Croydon Rural District Council not having been obtained. The London United Tramways Bill, the promoters of which are unable to obtain the consents of the Brentford Corporation and the Middlesex and Surrey County Council, has been referred to the Standing Orders Committee.

NEW COMPANIES

J. BONN & CO.—This company was registered on February 19th, with a capital of £1,500 in £1 shares, to take over the business of engineers, mechanical and electrical instrument and appliance manufacturers and model-makers, carried on by J. Bonn at 97 New Oxford-street, and 9 Lawrence Street, High Street, Bloomsbury, W.C., as "J. Bonn & Co." The subscribers are:—J. Bonn, A. E. Jones, Mrs. B. Bonn, Mrs. S. Jones, F. Mayer, W. H. Woodall, J. P. Whitehorne. No initial public issue. Registered without articles of association. The first directors are J. Bonn and A. E. Jones. Registered office, 97 New Oxford Street, W.C.

BRITISH MAGNETO CO.—This company has just been registered, with a capital of £1,000 in £1 shares, to carry on the business of electricians, manufacturers of, dealers in, and agents for the sale of all kinds of electrical apparatus for motor-cars or otherwise, motor ignition devices and electrical accumulators, motor-cars and boats, &c. No initial public issue.

Telegraph Traffic.—The cable between Trinidad and Demerara was restored to working order on the 21st instant. The via Hanekin land line route was restored on the 20th instant. We are further advised that the cable between Cayenne and Salinas (Brazil), belonging to the Compagnie Française des Cables Télégraphiques, which ceased working on January 27th, was repaired on the 24th instant, having thus been down for 28 days. This company's route via Haytî is therefore again open for traffic to South America. The storm which recently passed over Great Britain caused derangement of telegraphic wires, communication with Bolton, Blackburn, York, Middlesbrough, Darlington, Sunderland, and West Hartlepool being interrupted. Continental wires also suffered, some of the daily papers being without their market reports. Now that the French company's repairing steamer has completed the Brazilian repair, she will proceed to re-establish the Paramaribo-Cayenne cable. The following new telegraph offices have been opened in the United Kingdom, viz., at Carlton (Bedale), Easebourne (Midhurst), Hales (Market Drayton), King's Sanatorium (Midhurst), Llandefeilog (Llanelly), Portland, Flagship (Weymouth), Salsburgh (Motherwell), Station Road (Wescliff-on-Sea), and Tedburn St. Mary (Exeter).

Digitized by Google

APPOINTMENTS AND PERSONAL NOTES

The West Ham Electricity Committee have appointed Mr. Whitney, of the Midland Electric Corporation for Power Distribution, mains assistant.

Dr. William Mansergh Varley, assistant professor of physics and electrical engineering at the Heriot-Watt College, Edinburgh, and examiner in physics for the Central Welsh Board, has been appointed headmaster of the Devonport Technical School.

A recommendation by the Electric Light Committee of the Bray Urban District Council that the salary of Mr. McDonnell, assistant electrical engineer, be increased by £10 per annum, has been adopted.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton (last week, £58 10s. to £59 per ton).

HARRIS, LEE & CO.—In reference to the statement of affairs given in our last issue, a meeting of creditors was held on Wednesday last week, when Mr. Brown, of the Electrical Ordnance Co., occupied the chair. A cable was received from South Africa stating that the firm were unable to obtain an offer for the whole of the stock locally, and it was said to be understood that an offer would be made to continue the business on behalf of the creditors. In the result, however, it was decided that the liquidation of the company be proceeded with as quickly as possible with a view to an immediate winding up.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—In the bankruptcy of H. B. Budd, Ruminantly, East Grinstead, Sussex, the accounts show unsecured liabilities amounting to £1,022 12s. 5½d., and net assets estimated to realise £36 5s. 9d., or a deficiency of £986 7s. 0½d. The debtor for the last 12 months has had a business known as the Hastings & St. Leonards Electric Installation Co., at 37c Robertson Street, Hastings. A composition of 7s. 6d. in the £ has been approved.

Wireless Telegraphy.—The *Manchester Courier* states that the Council of the Liverpool Chamber of Commerce has adopted a resolution urging the Government to introduce wireless telegraphy installation in British possessions abroad. The president, Sir Alfred Jones, states that it was hoped the Colonial Office would establish the system in the West Africa, but they had urged it was not feasible, though Signor Marconi had expressed his confidence that there would not be the slightest difficulty in working it. Inquiries showed the cost of laying a cable for Southern Nigeria and Lagos would be about £20,000, and that the cable companies wanted a guaranteed income of £4,000 a year before they would lay the cable. As against this, the cost of installing wireless apparatus would be only about £2,000, and the cost of working about the same.

MISCELLANEOUS CITY NOTES

BROMPTON & KENSINGTON ELECTRICITY SUPPLY CO.—The directors recommend a final dividend on the preference shares at the rate of 7 per cent. per annum, and on the ordinary shares at the rate of 11 per cent., making 10 per cent. for the year. After crediting depreciation account with £8,000 and transferring to reserve £4,000 the sum of £10,156 is carried forward.

CHELSEA ELECTRICITY SUPPLY CO.—The directors recommend dividends for the half-year to December 31st, 1907, at the rate of 6 per cent. per annum on the preference share capital, and 5 per cent. per annum on the ordinary share capital of the company, making 6 per cent. and 4½ per cent. respectively for the year 1907, after paying debenture interest and placing £11,619 to depreciation fund, £519 to debenture premium redemption fund, and writing off £802 from the cost of extinction of founders' shares; carrying forward £904 as against £1,092 in the previous year. The dividends will be payable on and after March 16th, 1908.

COUNTY OF LONDON ELECTRIC SUPPLY CO.—The directors recommend a final dividend on the ordinary shares of 6 per cent. per annum for the half-year to December 31st, 1907, making 5 per cent. for the year. The sum of £25,000 has been transferred to reserve for depreciation, and £4,381 carried forward.

METROPOLITAN ELECTRIC TRAMWAYS.—It is stated that underwriting arrangements have been completed for an issue of £173,800 4½ per cent. debentures at 96 by this company. This issue will range *pari passu* with the existing £350,000 4½ per cent.

TELEGRAPH CONSTRUCTION AND MAINTENANCE CO.—The transfer books will be closed until March 3rd.

UNDERGROUND ELECTRIC RAILWAYS CO. OF LONDON.—It is stated that Messrs. Edwin Waterhouse, J. S. Phillips, J. B. Ackroyd, Thomas Skinner, and M. Prior, who, together with Mr. Lynden Macassey as secretary, agreed to act as an advisory committee to examine the scheme proposed by the Underground Electric Railways Co. of London, Ltd., and Messrs. Speyer Brothers for dealing with the profit-sharing notes issued by the Underground Electric Railways Co. of London in 1903, which mature in June, have held a number of meetings to consider the scheme in conjunction with the corresponding committees in Amsterdam and New York, and will complete almost immediately their investigation.

W. T. HENLEY'S TELEGRAPH WORKS CO.—A dividend of 15 per cent., less tax (including an interim dividend of 5 per cent. paid in December), has been declared upon the ordinary shares.

New Telephone Charges.—The Postmaster-General has sent a letter to Lord Joicey inviting the various Chambers of Commerce, which comprised the recent deputation concerning the telephone charges, to select a few of their number, say five or six, to discuss personally with him the questions in dispute. He states that for the discussion to be useful and complete, the smaller user should be represented as well as the large user. The Secretary of the Newcastle Chamber of Commerce has stated his intention of arranging the suggested conference.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **1/-** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 203–6, Temple Chambers, London, E.C.

SITUATION VACANT.

ASSISTANT DISTRIBUTING ENGINEER wanted near London. Previous experience with H.T. and D.C. mains, arc lamps, and meters essential. Preference given to a man suitable for interviewing consumers. Salary £78.

Apply, stating experience, age, and enclosing testimonials, to Box A55, ELECTRICAL ENGINEERING, 203, Temple Chambers, London, E.C.

APPOINTMENTS VACANT.

THE NATIONAL PHYSICAL LABORATORY.

VACANCIES OCCUR FOR TWO JUNIOR ASSISTANTS IN THE ELECTRICAL AND ELECTROTECHNICAL DEPARTMENTS. The stipends of Junior Assistants range from £100 to £150 a year. Commencing stipend according to qualifications. Apply before March 8 to the Director, National Physical Laboratory, Teddington, stating age, and giving details of experience and references. Applicants should have general workshop and practical electrical testing experience in addition to a good theoretical training. It is desirable that only copies of testimonials should be sent.

FOR SALE.

CITY OF BIRMINGHAM.

THE ELECTRIC SUPPLY DEPARTMENT have for disposal, at their Dale End Station, Eleven High Speed Engines and Dynamos; Six Lancashire Boilers; Four Babcock Boilers; Spare Armatures; Balancers; Boosters; Direct Current Motor-Transformers; Steam and Feed Piping; Fittings, &c.

The detailed list of the apparatus may be had by applying to the undersigned.

R. A. CHATTOCK,
City Electrical Engineer and Manager.

14, Dale End,
Birmingham.
27th February, 1908.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 20th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1906 Patents

24,232. BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*). The preparation of filaments for electric lamps. A metallic tungsten filament is heated to a temperature of approximately 500° C. in a chamber with a limited supply of oxygen. This filament is reheated to a high temperature in a vacuum. The filament then consists entirely of tungstous oxide, WO_2, and it is claimed to have a longer life than the ordinary metallic filament. Four claims, no figures.

24,253. BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts-Ges.*). Holders or supports for lamp filaments incandescing at high temperatures, composed wholly of, or having a surface coating only of pure thorium or magnesium oxide. The holder is moulded, heated to a temperature of at least 2,000° C., and then dipped in a mixture of hydrofluoric and sulphuric acid. The melting point of the final product is very high, so that there should be no danger of the filament becoming fused to the holder. Two claims, no figures.

1907 Patents

2,416. W. E. SUMPNER. The use of an auxiliary winding on the electromagnet or transformer portion of alternating-current instruments for the purpose of eliminating errors due to phase differences. The ends of the auxiliary winding are connected to the opposite plates of a condenser of such a capacity that the ampere-turns of the auxiliary winding are equal to the magnetisation ampere-turns of the primary winding. Four claims, five figures.

3,739. LANCASHIRE DYNAMO & MOTOR CO., WARBURTON, & KELSALL. A method of automatic control for motors driving punching and shearing or similar machines. When the period of heavy load comes on, and the motor slows down, the field is automatically increased, thus compelling the fly-wheel coupled to the motor to give up a large amount of energy and at the same time preventing the motor from taking too much power from the supply mains. When the load is taken off the motor accelerates and the field is automatically decreased, thus causing the motor to accelerate at a quicker rate and to take more power from the supply mains. A particular case of a series motor is described in the specification, in which the series winding is provided with a diverter rheostat controlled by shunt and series coils. Three claims, one figure.

4,364, BRITISH THOMSON-HOUSTON (*General Electric Co.*). An improved method for treating carbon filaments. The filaments are heated with a silicon-bearing substance, such as quartz, to a temperature of about 1,500° C. for about one hour. After this treatment the filaments are reheated in a vacuum furnace to a temperature of about 2,000° C. to drive out any volatile matter. These filaments give out a white light and have a high efficiency. Six claims, no figures.

4,706. HOWARTH (*Akt.-Ges., Brown, Boveri & Cie.*). The exciting windings of the interpoles of a single-phase motor are supplied by an alternating-current, generated by transformer action, in an auxiliary winding on one or both of the main poles. The interpole field consequently follows all the irregularities of the main field, and any electromotive forces induced by transformer action in the short circuited armature coils by the main field are exactly neutralised by electromotive forces induced by rotation in the interpole field. Inductive and non-inductive resistances are placed in the excitation circuit to adjust the magnitude and phase of the interpole exciting current. One claim, six figures.

4,742. BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). A single-phase motor without a commutator, but possessing the characteristics of a direct-current series motor. The motor is of the repulsion type, as the field winding only is connected to the supply. The rotating member is a ring on which is wound a ring winding and also a drum winding, both divided into sections, a section of the ring winding being in series with a corresponding section of the drum winding. Inside the ring is a stationary iron core set at about 45° to the axis of the main field, thus shunting part or all of the main field. Electromotive forces, induced by transformer action in portions of the ring winding, send currents through the corresponding portions of the drum winding, which set up a field at right angles to the primary field. A reaction between the stationary and rotary members is produced in consequence, which causes the ring to rotate. No E.M.F.s due to rotation are induced in the ring winding, but E.M.F.'s are induced in the sections of the drum winding, which oppose the E.M.F.'s induced by transformer action in the ring winding. The current and torque are thus reduced as the rotor speeds up. Two claims, two figures.

14,725, SIEMENS BROS.' DYNAMO WORKS (*Siemens Schuckertwerk-Ges.*). A quick-acting voltage regulator of the type in which a resistance in the field circuit of the exciting machine is periodically or intermittently short circuited and put in circuit in order to vary the exciting current in accordance with the load. The improvement consists of controlling the movable lever and contact by the differential action of two electromagnets with different time constants. Six claims, seven figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1906 Patent

24,923, RAWORTH. Electric traction control systems.

1907 Patents

440, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Elektricitäts Ges.*) Regulating A.C. commutator motors.
2,652, JOEL. Electric batteries.
2,675, CONNOLLY. Insulating electric conductors.
2,720, PATTERSON. Miners' electric safety lamps.
2,750, VON ZWEIGBERGK. Motor starting switches.
2,751, VON ZWEIGBERGK. Controllers for cranes, &c.
2,930, SUGDEN & RODWAY. Circuit breakers.
2,963, WELLINGTON & DANIELL. Arc lamps.
2,964, WELLINGTON & DANIELL. Arc lamps.
3,000 and 3,000A, BOULT (*Elektrizitäts Akt.-Ges. vorm. Schuckert & Co.*). Electrolytic apparatus.
3,060, JONES. Arc lamps.
3,693. HEPKE & DIENER. Fuses.
3,881, TORDA. Variable-speed motors.
6,455, LEA. Tumbler switch.
6,751, RAVENSHAW, MIDDLETON, & TOWNSEND. Magnetic clutches or brakes.
6,925, ATKINSON. Electric controllers or switches.
7,449, THORPE. Electricity meters.
8,642, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Mounting incandescent lamp filaments.
8,706, SCHMIDT. Interrupters for electric circuits.
9,294, HOLDEN & ELPHINSTONE. Automatic switches.
9,345, ELLIOTT. Electric pendant lamps.
11,071, ALLGEMEINE ELEKTRICITÄTS GES. Electrically-operated winding gear.
11,873, SIEMENS BROS. DYNAMO WORKS LTD., & POYNDER. Method of altering the working speed of polyphase motors.
14,100, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). Lightning arresters, &c.
16,574, LUNDBERG, LUNDBERG, & LUNDBERG. Switches.
17,308, WAPPLER & FAYER. Interrupters.
17,410, SIEMENS SHUCKERTWERKE GES. Switches.
17,717, COWPER-COLES. Electroplating.
19,794, GES. FÜR DRAHTLOSE TELEGRAPHIE. Detectors.
19,856, SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Shuckertwerke Akt.-Ges.*). Couplings for A.C. Generators.
20,185, AKTIEBOLAGET ALADDIN. Starting devices for vapour lamps.
20,676, CONRAD. Electrically-operated switches, &c.
21,035, YATES & LUM. Motor control.
21,119, VON PEEZ. Electric indicators.
22,746, SIEMENS & HALSKE AKT.-GES. Filaments for incandescent lamps.
24,706, JOHNSON & PHILLIPS, LTD., & TURBS. Arc lamps.
24,862, ARCIONI. Integrating train for double tariff meters.
27,933, UNTERBERG & HELMLE. Testing aparatus for magneto-electric ignition apparatus.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patents

21,584, BURKE. Dynamo-electric machines.
28,647, FESSENDEN. Production of high frequency oscillations.

1908 Patents

549, TRÜMPLER. Electrical heating apparatus.
1,159, THOMPSON. Regulation of alternating current circuits.
2,206, AMALGAMATED RADIO-TELEGRAPH CO. Radio-telegraphy.
2,375, HOWARD. A.C. relays.

Expiring Patents

No patents of electrical interest expire during the current week.

SUMMARY

The inquiry into the objections to the draft Home Office regulations relating to the use of electricity issued last year was opened by Mr. James Swinburne on Tuesday. At the commencement, the opposition asked that the following four questions of principle be considered and decided first before details of the various regulations were gone into:—(a) The question of dual control; (b) whether the limiting voltage to which the regulations were to apply should not be 250 instead of 100; (c) whether existing apparatus should be affected, *i.e.*, should the regulations be retrospective; (d) whether there should be an appeal from the decision of an inspector in enforcing the regulations. The case for the Home Office was opened upon these points, and Mr. G. S. Ram, the Electrical Inspector of Factories, gave evidence. It was stated that, as the result of a conference between the Home Office and the Board of Trade, the latter department has decided to relinquish Nos. A 1, A 24, and A 28 of its Regulations in order to eliminate any question of dual control. These concessions, however, by no means satisfy the opposition. Yesterday Mr. Swinburne stated that he could not make a preliminary report on the four questions of principle submitted above, and decided that the inquiry should take its normal course, and that the evidence put forward in support of the regulations should be completed. (Page 341.)

Considerable progress has been made with the extension to the Kingsway tramway subway, which is to connect the embankment lines with the northern system; and it is hoped that traffic will be commenced by the end of March. Most of the new subway is double-track tunnel, but a short length is composed of separate tubes for each track. A simpler form of conduit construction is used than in the case of the L.C.C. surface lines. (Page 343.)

The report and accounts of the Charing Cross, West End, and City Electricity Supply Co. for the year ended December 31st, 1907, show a considerable increase in business over former years. The combined costs of West End and City undertakings work out at 1·55d. per unit, including allowance for depreciation. (Page 347.)

A detailed description of the instrument employed in the directive wireless telegraph system of E. Bellini and A. Tosi, in order to vary the direction of communication while using fixed aërial conductors, is given in an article by these authors, together with a theoretical discussion of its action. A similar arrangement is used for receiving as for sending, and it is claimed that when receiving signals the bearings of the sending station can be determined within one degree.

Digitized by Google

By taking bearings of two known stations, a ship at sea can ascertain its position with considerable accuracy. (Page 348.)

A GREAT deal of attention is being paid to the manufacture of small transformers for reducing the supply voltage of alternating-current installations to a value suited to the most convenient forms of metallic filament lamp. A secondary voltage of 100 volts or thereabouts is sufficient in many cases, but in some installations where it is desired to use small units of light a voltage as low as 25 volts is sometimes used. In practically all cases auto-transformers with a single winding are used, as these are both simpler and more efficient than the type with separate primary and secondary windings; and advantage is obtained in cases where the secondary voltage is one-half or one-third of the primary by utilising all the sections of the transformers as a balancer, and dividing the load as equally as possible among them. By this means a smaller transformer may be employed, as the copper losses only correspond to the out-of-balance current. This arrangement entails very little alteration to the wiring of an existing installation. A form of transformer is also made for use with single lamps or groups of lamps which are switched on and off together. This can form a part of the fitting, and avoids no-load losses when the lamps are not in use. (Page 351.)

THE East Ham telephone exchange of the National Telephone Co., opened last January, is typical of the latest practice in small common battery exchanges. A multiple switchboard is employed with a present accommodation for 500 lines, and an ultimate capacity of 800 subscribers' lines. Electromagnetic calling signals are used instead of lamps, and these are restored by gravity when the current is cut off from the magnet coil by the insertion of the answering plug. The subscribers' operators' cord circuit is divided by condensers instead of by a repeating coil, and a 16-cell battery is employed instead of 11 cells. (Page 355.)

A NEW type of solenoid-operated controller for printing-press motors, which presents some new features, is described in an illustrated article. (Page 358.)

THE report of the Departmental Committee appointed to inquire into the working of the National Physical Laboratory recommends that the ordinary testing of materials to ascertain if they fulfil the requirements of contracts should, with certain exceptions, not be undertaken by the Laboratory, and should be left to private practitioners. On the other hand, the rule as to compulsory publication of the results is to be relaxed. In addition to publishing the contents of the report, we give several extracts from the evidence, the most interesting of which relates to a request by Sir JOSEPH SWAN, that could not be granted, that the Laboratory should undertake for him certain investigations with regard to the properties of certain refractory metals and metalloids, the results of which, Dr. GLAZEBROOK said, might have had a great influence on the metallic filament lamp industry in this country. (Page 359.)

THE bulk supply to the Middlesbrough Corporation from the Cleveland and Durham County Electric Power Company will be commenced in a few days. A substation has been constructed, which receives current at 11,000 volts, three-phase, and supplies continuous current from two 700 kw. rotary converters. (Page 362.)

AN illustration is given of a new pattern of electric kettle. (Page 362.)

AN article upon impressions produced by electric waves upon photographic plates is abstracted under "Electrochemistry and Electrometallurgy." JOSEF RIEDER finds that glass plates upon which an image has been impressed and then coated with aluminium powder will then reproduce that image when subjected to the action of electric impulses. The metallic image, in fact, behaves as a coherer. The German Government has recently erected an electrolytic plant capable of producing 600 cubic metres of hydrogen gas per 24 hours. The plant has been specially installed for the purpose of inflating army balloons. (Page 363.)

TANTALUM lamps in a number of sizes are now available for use on alternating-current circuits. (Page 363.)

UNDER "Electrical Science," in the British and American section, is a note of a Paper on the constant E.M.F. between mercury and certain electrolytes. P. WALDEN formulates a law connecting dissolving power with specific inductive capacity. Miss GLEDITSCH tests Ramsay's connection between radium, copper, and lithium by the spectroscopic analysis of radium minerals. (Page 364.)

AMONG the specifications published by the Patent Office on Thursday last is that by A. D. JONES, describing the composition used for filling the grooves of the positive carbon of the Jandus enclosed flame arc-lamp, which was described in our last week's issue. One by the BRITISH THOMSON-HOUSTON Co. covers a method for fusing metallic filaments to the leading-in wires in incandescent filament lamps; and SIEMENS & HALSKE have one relating to metallic filaments with coatings of another metal. SIEMENS BROS. DYNAMO WORKS and H. B. POYNDER have patented a modification of their method of speed control for polyphase motors. An abstract of the specification covering their method was published in ELECTRICAL ENGINEERING, February 20th, 1908, p. 285. (Page 365.)

AN inquest has been held at Birmingham with regard to the death of a tramway conductor caused by the overturning of a car. Sir ALEXANDER KENNEDY has declined to accept the appointment of consulting electrical engineer to the Burgh of Dunfermline, in consequence of the rejection of his recommendation that the Council's Provisional Order should be transferred to the Fife Electric Power Co. A large increase in the deficit of the Hastings Corporation Electricity Department is expected, which, it is alleged, is partly due to reduced income from private lighting owing to the increased use of metallic filament lamps. The Works Committee of the Paddington Borough Council have recommended that an offer by the Metropolitan Electric Supply Co. for lighting a portion of Harrow Road with 66 flame arc lamps in place of gas lamps be accepted; but the matter is still under discussion. (Page 367.)

IT will be moved in the House of Lords to-day that the London Electric Supply Bills be referred to a Joint Committee of both Houses. The second reading of the Cavehill and Whitewell Tramways Bill has been rejected. (Page 369.)

AN expenditure of £35,967 has been authorised in Hull by the Local Government Board, largely for the renewal of old cables and the laying of additional mains. The Napier (New Zealand) Municipality invites offers for the construction of tramways. Tenders for generating plant are invited at Heywood, Stoke-upon-Trent, and West Ham. (Page 370.)

THE Westminster City Council has accepted the tender of the Westminster Electric Supply Co. for the lighting required in connection with the Marble Arch Improvement Scheme, in preference to the tender of the Gas Light and Coke Co. The lamps will be flame arcs; the Gas Company tendered for high-pressure incandescent gas lamps. Subject to Parliamentary sanction, the Tramways Committee of the Ilford Urban District Council has recommended provisionally the adoption of the "Robrow" surface-contact system for a section of their tramways. The Walthamstow Urban District Council has accepted the Vulcan Boiler & General Insurance Co.'s tender for the insurance against breakdown of eleven armatures at the electricity works at a yearly premium of £90. (Page 371.)

THE question of underground telephone wires in

Digitized by Google

London has been again before the London County Council. Although the Post Office can lay these without payment to the Council, and can rent them to the National Telephone Co., the Council still insists on a rental being paid by the company if they lay the wires themselves. (Page 372.)

A letter from the Jandus Arc Lamp and Electric Co., received as we go to press, makes clear the points of difference between the new Jandus enclosed flame arc lamp, described in our last issue, and the Blondel Lamp. (Page 373.)

The increased earnings of the South Metropolitan Electric Light and Power Co. for the past year have amounted to over 8 per cent. on the additional capital expenditure during the year. Meetings have been held during the week of the London Electric, Charing Cross and City, Kensington and Knightsbridge, and Westminster Supply Companies, at which the reports given in previous issues of Electrical Engineering were adopted. The report of the Metropolitan Electric Supply Co. shows an increase in the gross revenue of £3,048, and an increase of working expenses of £395. The further dividend of 3s. 6d. per share makes a total distribution for the year of 6½ per cent. The report of the Brompton and Kensington Electric Supply Co. shows a credit balance on the revenue account of £31,718. The dividend on the ordinary shares had been at the rate of 10 per cent. for the year. The accounts of the Cambridge Electric Supply Co. show a profit for the year of £8,292; the dividend for the whole year is 6 per cent. The final dividend of the Telegraph Construction and Maintenance Co. makes a total of 17½ per cent. for the year. Some objections have been lodged to the appointment of the liquidators of Messrs. Bruce Peebles & Co. (Page 374.)

The opposition against the imposition by the Home Office of new Regulations as to the employment of electrical energy in factories is very real. No less than 185 sets of objections had been lodged for consideration at the official inquiry by Mr. Swinburne which commenced on Tuesday. The need for additional official control has certainly not been made apparent in the statement made by Mr. Ram, and we maintain the opinion that in the case of premises supplied with electrical energy the present Board of Trade regulations are amply sufficient. They protect the public, it is argued, and not the workman, but since the means of protection are the same in both cases there is no need to make a change. It might have been expected that Mr. Ram would come provided with a long list of serious accidents due to causes not preventable if the Board of Trade Regulations were regarded, but preventable under his new code, but this course has evidently not been applicable, as the number of serious and fatal accidents due to the utilisation of electricity in works has been extremely low.

The question of suitable supply voltages for incandescent lighting, which, after an acute controversy between the interests of the lamp-maker and the supply authority, was practically settled in favour of standard pressures of about 200 volts, has been reopened by the introduction of metallic filament lamps, for these at the present time can only be made suitable for such circuits in sizes forming an inconveniently large light unit to substitute for the carbon filament lamps commonly used in existing installations. We will not attempt to predict what the future will bring forth in this respect, but what we desire to call attention to is that, in the present state of the art of lamp manufacture, the advantages of high-efficiency metallic filament lamps can in many cases only be made available where a much lower pressure than 200 volts is obtainable. A certain amount is, of course, done by running lamps in series, but the disadvantages of this method are obvious. On alternating-current circuits the best course is to adopt small transformers on consumers' premises; and an article on another page describes the results of the activities of a number of manufacturers in this direction. The transformers used are, in practically all cases, of the auto-transformer or single-winding type, as this gives advantages both as regards cost and efficiency; and wherever the conditions of the installation allow they should be connected up as balancers, and the circuits divided up into two or more sections as equally loaded as possible. This arrangement, especially in installations of fair size, entails less alteration to existing wiring than might be at first supposed, and results in a very considerable saving in the copper losses, as the transformer only has to carry the "out of balance" current, and indirectly in the iron losses, as a smaller apparatus can be used. Owing to the much higher efficiency of the metallic filament lamp as compared with its predecessor, the currents which the wiring and fuses will have to carry will, notwithstanding the lower voltage, not be increased above their value under the old conditions. In some installations groups of lamps always switched on and off together may have their own transformer, as then the open-circuit loss when the lamps are not in use can be avoided.

The report of the Departmental Committee with regard to the working of the National Physical Laboratory, and the Blue Book containing the evidence, affords interesting reading, and the result will be that a check will be put to some extent on the commercial testing of samples in competition with consulting engineers and private testing laboratories. Although the amount of work done so far in this direction by the Laboratory has not been great, it is evident that an extension of it was in contemplation by the long tariff of tests published in a pamphlet which has been circulated freely by the Laboratory, and by the fact that the fees for these tests were based practically on less than cost price. It appears that the charges were based on an estimate of the actual cost of labour and material, increased only by 15 per cent. The Laboratory has no rent to pay, and no allowance was made for this, nor for the fact that costly instruments have to be bought and maintained and an expensive organisation kept up, so that the subsidy given by the Government and private benefactors was actually being used to divert business from some of the best and most useful workers in the engineering professions. The statement that this competition at "cut" prices was unintentional must, of course, be accepted unreservedly, but that it existed and was capable of serious development is none the less certain. The Laboratory is in a position to do a vast amount of useful research work, and, in fact, it has already produced some valuable results, and this is the more reason that a policy should be followed which will enable it to proceed unhampered by jealousies and free from sordid business considerations which must be particularly unattractive to the distinguished scientific gentlemen who are responsible for the work and organisation of the institution.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MARCH 5TH.

Royal Society.

4.30 p.m. Meeting at Burlington House, Piccadilly. Among the Papers to be read are the following:—(1) "On the Electrical Resistance of Moving Matter," by Prof. F. T. Trouton, F.R.S., and A. O. Rankine; (2) "On the Nature of the Streamers in the Electric Spark," by Dr. S. R. Milner.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, S.W. Paper to be read: "Fuse phenomena," by Prof. A. Schwartz and W. H. N. James.

Röntgen Society.

8.15 p.m. Ordinary General Meeting at 20 Hanover Square, W., when Dr. Deane Butcher's Paper on "Recent Improvements in X-ray Apparatus," will be discussed.

SATURDAY, MARCH 6TH.

Royal Institution.

3 p.m. Afternoon Lecture I., by Prof. J. J. Thomson, F.R.S., on "Electric Discharges through Gases."

TUESDAY, MARCH 10TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology, Whitworth Street. Paper to be read:—"Electrical Testing," by A. E. Jepson.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Special Meeting at the University, when Mr. W. Rosenhain will deliver a lecture on "The Internal Structure of Metals."

Institution of Electrical Engineers: Glasgow Local Section.

8 p.m. Meeting at 207 Bath Street, Glasgow.

WEDNESDAY, MARCH 11TH.

Institution of Electrical Engineers: Birmingham Local Section.

7.30 p.m. Meeting in the University. Paper to be read:—"Artificial Load for Testing Electrical Generators," by R. K. Morcom and D. K. Morris.

Association of Engineers-in-Charge.

7.30 p.m. Meeting at St. Bride's Institute, Fleet Street, London. Paper to be read:—"Notes on Electric Lifts," by H. D. Wilkinson.

Incorporated Institution of Automobile Engineers.

8 p.m. Annual General Meeting at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London. Paper to be read:—"Some Problems Peculiar to the Design of Automobiles," by F. W. Lanchester.

THE PROPOSED HOME OFFICE REGULATIONS

(Special Report. Strictly Copyright)

THE inquiry ordered to be held by the Home Office into the objections against the new draft regulations issued in August last year for the generation, transformation, distribution, and issue of electrical energy in premises under the Factory and Workshops Act, 1901, was commenced by Mr. James Swinburne, F.R.S., at Caxton Hall, Westminster, on Tuesday. The regulations in question, which were given at length in ELECTRICAL ENGINEERING, Vol. II., p. 282, apply to systems in which the normal working voltage is over 130 volts for continuous, or over 65 volts for alternating. The usual definitions of high and low pressure are employed, low pressure meaning a pressure not exceeding 250 volts, medium pressure meaning a pressure normally above 250 volts but not exceeding 650 volts, high pressure meaning a pressure normally above 650 volts but not exceeding 3,000 volts, and extra high pressure meaning a pressure normally exceeding 3,000 volts.

No less than 185 sets of objections have been lodged against the regulations, these representing supply authorities, both company and municipal, consumers, chambers of commerce, &c., throughout the kingdom. As many of these sets of objections represent the views of a number of authorities or persons, the actual number of objectors is very considerably greater than 185. The Home Office are represented at the inquiry by Mr. J. H. Gray and Mr. Raymond Asquith, and the official witnesses are Mr. J. Scott Ram, the Electrical Inspector of Factories to the Home Office, Mr. W. H. Patchell, and Mr. J. F. C. Snell.

At the commencement of the proceedings Lord ROBERT CECIL, K.C., M.P., who represents the London electric lighting companies and some others, suggested that as there were several questions of principle to be settled before the details of the regulations were discussed, the Commissioner should take these first and give a decision upon them. These points he defined as follows:—(*a*) The question of dual control; (*b*) whether the limiting voltage to which the regulations were to apply should not be 250 instead of 130 volts; (*c*) whether existing apparatus should be affected, *i.e.*, should the regulations be retrospective; (*d*) whether there should be an appeal from the decision of an inspector in enforcing the regulations.

This view was supported by many of the representatives of other objectors, and it was decided that Mr. Gray should open the case for the Home Office on these points first.

Mr. GRAY said he thought that one matter in connection with these regulations had been quite misapprehended, viz., the difference between the function of the Home Office in the administration of the Factory Acts, and the Board of Trade in the administration of the Electric Lighting Acts. The difference in the functions of these two authorities was responsible for a certain inconsistency in the objections to the regulations now under discussion, in that it did not seem to have been fully recognised that whereas the object of the Home Office was to protect the employees, the object of the Board of Trade in its regulations was to protect the public. The present code of regulations had been prepared by Mr. Ram, not as the result of consideration in his chair, but as the result of several years continuous examination and investigation into all the methods of electrical generation in the various installations throughout the country. That there should be two sets of regulations with the same object in view he agreed was unnecessary, and would be unwieldy. This ought to be avoided, and with this object in view a conference had taken place between the officials of the Home Office and the Board of Trade, the result of which was that the Board of Trade was prepared to relinquish certain of its regulations, which it was conceivable would clash with those now proposed by the Home Office. This he thought settled the question of dual control.

These regulations are Nos. A1, A24, and A28. We give them below:—

1. *Pressure of Supply to Consumers.*—The pressure of a supply delivered to any consumer shall not exceed the limit of low pressure, except for special purposes, for which a medium pressure supply may be given on the consumer undertaking to comply with the following conditions:—

(*a*) Where the supply is for power purposes:—

(1.) The frame of every electric motor shall be efficiently connected with earth.

(2.) The consumer's wires forming the connection to motors, or otherwise in connection with the supply, shall be, as far as practicable, completely enclosed in strong metal casing efficiently connected to earth, or they shall be fixed in such a manner that there shall be no danger of any shock.

(3.) The supply to every motor shall be controlled by means of an efficient cut-off switch, placed in such a position as to be easily handled by the person in charge of the motor, and connected so that by its means all pressure can be cut off from the motor itself, and from any regulating switch, resistance, or other device in connection therewith.

(4.) Switches, efficient fuses, or other automatic circuit-breakers, shall be provided so as to protect the circuits from excess of current, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

(5.) A notice shall be fixed in a conspicuous position at every motor and switchboard in connection with the supply forbidding unauthorised persons to touch the motors or apparatus.

(*b*) Where the supply is for arc lamps in series:—

(1.) The consumer's wires forming the connection to the arc lamps, or otherwise in connection with the supply, shall be, as far as practicable, completely enclosed in strong metal casing efficiently connected with earth, or they shall be fixed in such a manner that there shall be no danger of any shock.

(2.) The supply to every arc lamp shall be controlled by means of an efficient cut-off switch, placed in such a position as to be easily handled by the person in charge of the arc lighting, and connected so that by its means all pressure can be cut off from the arc lamp itself, and from any regulating switch resistance or other device in connection therewith. Provided that where the arc lamps are connected in series across the outer conductors of a three-wire system, it shall be sufficient if one such switch be provided for each series of arc lamps.

(3.) Switches, efficient fuses, or other automatic cut-outs shall be provided so as to protect the circuit from excess of current, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

(*c*) Where the supply is for incandescent lamps in series:—

(1.) The consumer's wires forming the connection to the incandescent lamps or otherwise in connection with the supply, shall be completely enclosed in strong metal casing, and this casing,

Digitized by Google

together with the switches and lamp-holders, if metallic, shall be efficiently connected with earth.

(2.) Switches, efficient fuses, or other automatic cut-outs shall be provided so as to protect the circuits from excess of current, and all switches and cut-outs shall be so protected that there shall be no danger from the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

Where the supply is for any special purpose other than those above-mentioned, or where the pressure of the supply exceeds the limits of medium pressure, it shall be subject to such other regulations as the Board of Trade may from time to time prescribe.

24. *Responsibility of Undertakers for their Lines, &c., on Consumers' Premises.*—The undertakers shall be responsible for all electric lines, fittings, and apparatus, belonging to them, or under their control, which may be upon a consumer's premises, being maintained in a safe condition, and in all respects fit for supplying energy.

28. *Transformers and High-Pressure Apparatus to be Enclosed in Metal, &c.*—Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on a consumer's premises, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself, so far as they are on the consumer's premises, shall be enclosed in solid walls or in strong metal casing efficiently connected with earth, and securely fastened throughout.

The next objection was as to whether the rules should be made retrospective. He agreed that it would be exceedingly hard if these rules, which were primarily intended to deal with the future, should be so drafted as, to a large extent, to make even a small proportion of the existing works impossible to be carried on, and it was with this object in view that the exemptions had been provided. The last exemption had been specifically drafted to protect existing undertakings. It reads as follows:—"If the occupier can show with regard to any requirement of these regulations, that the special conditions in his premises are such as to prevent danger not less adequately than if the said requirement were observed, that requirement shall be deemed to be satisfied." One great object of the Home Office had been to keep these rules in their shortest and simplest form, and to make them as little cumbersome as possible, and for this reason he would ask objectors to think twice before they suggested the addition of a large number of words or of additional rules. If the objects aimed at could be effected by the present rules or by a very small number of alterations, then he thought it should be done, but his instructions were that, rather than load up these rules with numerous specific exceptions or specific provisions, the Home Office would drop any particular rule. He thought the objectors in many cases would be well advised to leave the rules in their present form, because this would lead to a proper business-like working of their undertakings, far more than if many modifications were inserted.

The third point was as to the right of appeal. This question arose to some extent out of the exemption clause which he had just read. That there should be some form of appeal appeared to be fair, but the procedure was such that an appeal was always obtained in the very best possible form. Many of the objectors asked that there should be an appeal to some third party or that arbitration should be resorted to, or some other form of procedure, which would enable each occupier to raise the question before the matter became one for prosecution for breach of the rules, or failure to comply with them. In the application of these rules, the following would be the procedure. The Factory Inspector for any particular district would carry out his usual inspection to find out whether the rules had been complied with. It was his duty to point out to the owner when a breach was being made, or when an omission was made. If the owner did not make the breach good, if it could be made good, then, of course, the inspector would report to the Home Office. Reports of all electrical matters came before the electrical inspector, and unless the electrical inspector was satisfied with the report, one way or the other with regard to the complaint, he would visit the place, if he thought it necessary, and examine the matter for himself. He would allow the occupier a full hearing, and then consider the report of the inspector and any statement made by the occupier together. This, he submitted, was really a true solution of this objection, but at the same time he thought the Home Office would be prepared to go further. In addition to what he had just stated with regard to procedure, the owner should be given an opportunity of making a statement in writing to the electrical inspector, who would then be in a position to consider the report of the inspector on the one hand, and the statement of the occupier on the other. If after this any prosecution was instituted by the Home Office, obviously it was in the interests of those responsible for the prosecution being instituted to take the utmost care that they were not fighting for form, but for substance. The suggestion that an appeal should be made to another Government body, seemed to him impossible.

The next question of principle was that the regulations should not be enforced as regards any voltage under 250, whether alternating or continuous current. This provision had been subject to a good deal of criticism, and in reading the many objections, it was clearly seen that there had been a good deal of misconception due to a confusion of the functions of the two Government departments, namely, the Home Office and the Board of Trade. It was stated in the objections that the Board of Trade regulations stated that 250 volts was perfectly safe. He joined issue with this at once. What the Board of Trade regulations did say was that nothing beyond a certain voltage should be used, and all the Home Office regulations provided was that to any pressure below 65 volts alternating and 130 volts continuous their regulations would not apply. If the regulations were altered in this respect, it would not be with the consent of the Home Office. This particular point had been given the most careful consideration, and as a result of the investigations made by the electrical inspector, and the information he had received during his term at the Home Office, it had been decided that the voltages named in the regulations must remain. The reason for this attitude was that the advisers of the Home Office believed that 100 volts alternating current was dangerous to life, or in certain circumstances lower voltages were dangerous to health or limbs. He ventured to ask any electrical engineer whether he would be prepared to take into his hands two good metal terminals at 100 volts alternating current properly connected. Not only was it impossible for some people to hold 100 volts, but it was impossible for them to hold 25 volts alternating current, and this made it a very serious matter, for there were other dangers to be thought of. Suppose a workman on a platform, somewhat raised from the ground, accidentally brought some part of his body, unprotected, in contact with 25, 30, 40, or say 50 volts alternating or continuous current. The mere temporary contact with a bare conductor would be sufficient to startle him, and to make him fall from his position and consequently to suffer injury, although the supply was at such a low voltage. The officials of the Home Office had endeavoured so to draft these rules, and to specify the restrictions as to consider not only the safety of the workmen, but also that the electrical industry should not be unduly restricted by unnecessary regulations. On this account many things had been omitted from the draft which, in the opinion of the advisers of the Home Office, might very well have been included to bring them into conformity with the practice which had existed in the administration of the Factories Act in connection with matters other than electrical ones, as regards taking proper steps for the protection of the workmen. One or two objectors had raised the question that these regulations would cost a good deal of money, but he would say once and for all that the question of money was no answer in itself, and any objections on this ground alone appeared to him to have no substance. If to prevent the loss of human life it was necessary to have enormous expense, then this expense must be incurred of necessity.

Mr. G. SCOTT RAM, the Electrical Inspector of Factories, said he had been responsible for the investigations, upon which these regulations were drafted. Dealing with the question of dual control, he said the Board of Trade had agreed, so far as factories were concerned, to withdraw the regulations already mentioned dealing with the wiring of consumers' premises. The other points in the two sets of regulations which more or less overlapped had reference to the consumers' services where the supply was given from the public mains, and in some cases there was a high pressure supply which would also include transformers and the switching device on the consumers' service. He proposed to insert at the commencement of the third exemption the following addition: "Nothing in these regulations shall apply on the premises of an occupier being a consumer of an authorised electric supply undertaking, to any service cables, and apparatus on the supply side of the occupier's terminals belonging to, or under the control of, the authorised undertaking." This exemption would have some effect on the following rules in the present draft, viz., Nos. 1, 2, 5, 6, 7, 8, 9, 10, 21, 25, 26, 27, 28. With regard to the question of appeal, he proposed to add the following exemptions, making four in all: "In case any difference of opinion shall arise between an inspector and occupier under these regulations, the occupier shall be entitled to make a statement in writing for submission to the Electrical Inspector." He thought that the exemptions were sufficient to do away with the objections raised as to the application to existing works. With regard to the voltage, the Home Office was not prepared to accept anything higher than 65 volts alternating current, and 130 volts continuous current.

LORD ROBERT CECIL, K.C., M.P., cross-examined Mr. Ram on behalf of the London Electric Lighting and other companies. On the question of dual control, Mr. Ram agreed that it would not do to have two authorities controlling the application of electricity, and although the Home Office hoped that it had eliminated this dual control, if it could be shown that it still existed, they must find a way out of it. The witness's attention was drawn to regulation No. 1, which he agreed was somewhat widely drawn, and would allow the Home Office to have any alteration made it might think fit. He would not agree that the possibility existed of the Board of Trade requiring alterations one month and the Home Office coming along a month later and saying they were quite wrong. His opinion was that this contingency could not arise if regulation A 1 of the Board of Trade was withdrawn as proposed. Similarly, with regard to the construction of sub-stations, Mr. Ram refused to admit that there would be dual control, his view being that whereas the control of the Board of Trade related only to the construction of sub-stations from the point of view of the safety of the

Digitized by Google

public, the Home Office wished to protect the workpeople in the sub-stations. These matters had been very carefully discussed between the Board of Trade and the Home Office, and it had been concluded that there would be no difficulties of the sort pointed out.

Lord Robert Cecil said that his clients wished it to be clearly understood that there was to be no sort of double control, and, to be frank, they preferred the Board of Trade to the Home Office.

After further cross-examination upon the points as to why it was proposed to exempt consumers' service lines from the regulations, to which Lord Robert Cecil stated that he could get no satisfactory reply, counsel suggested that the only way out of the difficulties which the electric supply companies, represented by him, felt themselves to be in with regard to these regulations, was to embody some such exemption as that proposed in the following clause :—"Nothing in these regulations shall apply to any generating station, sub-station, conductors' cables, or apparatus of, or belonging to, any company, body, or person authorised by Special Act, Licence, or Provisional Order, to supply electrical energy for any public or private purpose, and complying with the regulations made by the Board of Trade under any such Special Act, Licence, or Order for securing the safety of the public, or to any system connected therewith, and also complying with any such regulation."

The object of this, it was stated, was to exempt everybody who is under the control of the Board of Trade at present. Having pointed out further instances of dual control in connection with the Electric Lighting Clauses Act of 1899, Counsel put to Mr. Ram the question as to why the regulations under the Coal Mines Act were less stringent than those now proposed. Mr. Ram refused to admit this. Further instances were put to him of generating stations already existing in which a strict compliance with the proposed regulations would involve such enormous expense as to render the carrying on of their business impossible. The reply was made that there would always be some means of getting over such difficulties. On the question of the appeal to the electrical inspector against the requirements of an inspector of factories under these regulations, Lord Robert Cecil said he regarded this as little better than a farce; it merely called the attention of an occupier to the existence of the penny post in that he could write a letter.

LORD ROBERT CECIL.—We ask for some real reconsideration by an impartial person before we have to go to any very large expense.—I do not think this is required or necessary.

We are not satisfied with an appeal to a magistrate on such a technical matter; we want an appeal to an impartial arbitrator as provided in the Coal Mines Regulations Act. I do not think this is reasonable because you have anything you want as it is.

Lord Robert Cecil suggested that there should be added the words, "an appeal to a competent, fully qualified person not being an official nominated by the Home Office on the application of either party." Asked as to why the limit had been placed at 150 volts continuous and 65 volts alternating, Mr. Ram stated that it was not deemed necessary to go below this, as they would then be making regulations for such things as electric bells. As a matter of fact, he did not think these regulations were as stringent as the Board of Trade regulations in this respect.

Cross-examined by Mr. VESEY KNOX, K.C., on behalf of the Newcastle Electric Supply Company and the Cleveland and Durham County Electric Power Company, Mr. Ram agreed that the rules might be modified so that no action could be taken against an occupier for alleged breach of the rules without a certificate from the electrical inspector stating that there was a cause for prosecution. Counsel pointed out that as the rule stood at present he saw nothing to prevent, for instance, representatives of a workmen's union from taking action against an occupier in the interests of the men, on quite trivial points.

On the question of passage ways on switchboards, Mr. Ram stated that, some of the switchboards of the Newcastle Co. were very excellent, and he often quoted them as models to other people. He knew that the company owned about 200 boards, and that many of them did not comply with the proposed regulations that there should be a height of 7ft. and a width of 3ft. on passage ways. He did not, however, think it would be necessary to reconstruct all these, as he thought the owners could easily prove their claim to exemption. Generally he got over these difficulties by friendly discussion.

Mr. VESEY KNOX.—Why, then, if you have got on so well in the past, do you wish to have these regulations?—We must have the regulations to draw attention to the dangers. Merely pointing them out in a memorandum is not sufficient in many cases.

In answer to further questions, Mr. Ram stated he regarded the distance set out in the regulations for switchboards passage ways as being a useful standard. If, however, the boards could be made safe by other means, all well and good.

Questioned by Mr. W. B. Woodhouse, on behalf of the Yorkshire Electric Power Co., the Incorporated Association of Electric Power Companies' Officials, and the Leeds Chamber of Commerce, on the question of the voltages of 65 and 150 respectively, Mr. Ram refused to admit that whereas a power company supplying a sub-station at 10,000 volts would be exempt, so far as the sub-station was concerned, if they supplied at lower pressure, they were not exempt. Mr. Ram also refused to admit that the latest Board of Trade regulations were less stringent than those issued in 1906. On the point of all metal work having to be earthed, Mr. Woodhouse asked if Mr. Ram had considered the case of the Thury system; Mr. Ram's reply was that in this case it would be unnecessary, and, in fact, it would introduce a danger if this regulation were enforced.

In reply to questions on behalf of the Barry Railway Co., Mr. Ram stated that he saw no reason to produce particulars of the accidents which had induced the Secretary of State to certify that electrical generation was dangerous. Neither could he call to mind at the moment any accident upon the passage way less than 3ft. wide.

Mr. SYDNEY MORSE put several questions as to the exemption of the consumers' service lines, upon which a certain amount of doubt seemed to exist.

Mr. SWINBURNE stated that his difficulty on this point was that he understood an occupier could not be made to keep a fuse in proper order because it did not belong to him, and therefore there was a difficulty in enforcing the law against an occupier as regards his fuse, but it did not follow that the rules were not to be enforced against a supply company, and yet he did not see how this was to be done, because the place was not a generating station.

Mr. MORSE stated that he felt the occupier would be held to be the occupier of the premises in respect of such a fuse or switch.

Mr. GRAY, on behalf of the Home Office, said this exemption had been modified in order to prevent an occupier being held responsible for a switch, which he was under a penalty not to touch; therefore it had been decided to leave this matter under the control of the Board of Trade.

In reply to further questions by Mr. Morse, Mr. Ram stated that the proposal at present was that the Board of Trade regulation, A 1, would cease to exist if the Home Office regulations were passed. Further questions by Mr. Morse were directed to the points that the expense of complying with the regulations on the part of small existing undertakings would be prohibitive, and that for economical reasons the station would have to be closed. Mr. Ram repeated his previous answers that difficulties such as these could be got over by friendly discussion, but Mr. Morse pressed the question as to what would happen to supply companies which had had an accident whilst not complying with the Home Office regulations, and to which there could be no defence. No expression of opinion was made.

The next question was as to the use of switches in the holders of portable lamps. Considerable discussion took place between Mr. Morse and the witness as to particulars of accidents due to this cause. Mr. Ram stated that he could not remember any off-hand, although there had been several in small workrooms coming within the Factory Act. Mr. Morse's contention was that there had been none, and that if the Home Office regulations were carried out, very considerable expense would have to be incurred in fitting these lamps with switches.

The TOWN CLERK OF EDINBURGH asked if Mr. Ram would agree to the regulations only applying to new work and not to existing stations. Mr. Ram was unable to give a definite reply.

At the close of Mr. Ram's re-examination,

LORD ROBERT CECIL asked that the four main questions of principle referred to at the commencement of the proceedings should first be disposed of. If Mr. Swinburne's report was favourable this would dispose of a large number of objections to individual regulations, and thus shorten the proceedings very much.

After some further discussion, Mr. Swinburne stated that he would consult with the officials of the Home Office, and state the decision arrived at the next morning.

WEDNESDAY, MARCH 4TH.

Mr. SWINBURNE said that with regard to giving an interim report as suggested, the Home Office does not see their way to accede to this. But he did not wish to put the whole responsibility upon the Home Office. He himself felt that the course suggested would put him in the position of having to decide something before he had heard the whole question. He would have to decide, for instance, whether there was to be overlapping before it was really settled what the new rules were to be. He therefore thought it best to go on with the inquiry. Dealing with the question of expense, Mr. Swinburne stated that whilst they were all anxious to reduce this as much as possible, the electrical industry was still young, and the expense to be incurred must not be considered merely from the point of view of the importance of this inquiry. They were endeavouring to make rules which would have far-reaching importance, and therefore they should not shirk their responsibilities in any way. The inquiry will take the normal course, viz., that the Home Office shall put forward evidence in support of the regulations, after which speeches will be made on the questions of principle which have been raised with the object of ascertaining whether a decision can be given upon these as distinct from the detailed regulations.

Mr. G. SCOTT RAM then went through the regulations *seriatim*, giving the reasons for them, and indicating certain modifications to meet objections. We will give a full report in our next issue.

THE ALDWYCH-EMBANKMENT L.C.C. TRAMWAY SUBWAY

SINCE the opening of the service of cars in the subway running from the southern end of Kingsway to Theobald's Road in February, 1906, and the

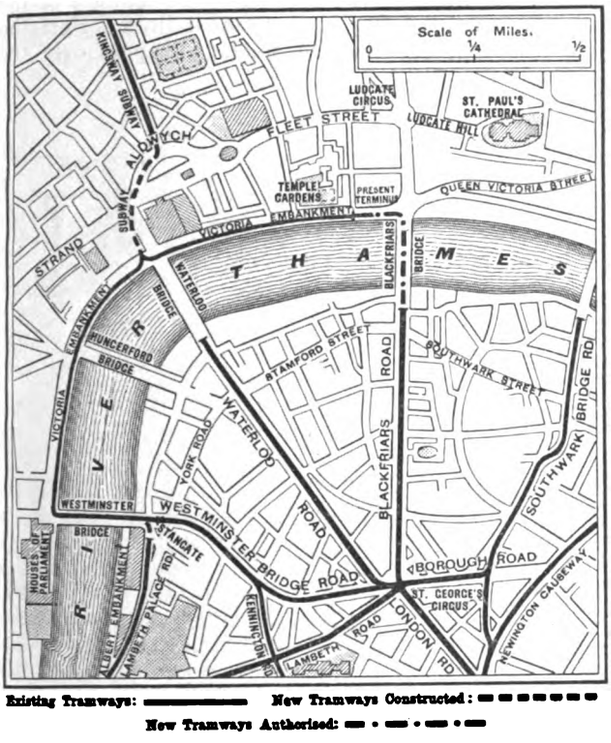

FIG. 1.—MAP OF ROUTE, SHOWING JUNCTIONS WITH EXISTING TRAMWAYS.

inauguration in the December of the same year of the tramways over Westminster Bridge and along the Embankment, the only link remaining uncompleted in the joining up of the northern and southern portions of the London County Council tramway system, apart from the alternative route over Blackfriars Bridge, has been the extension of the first portion of the subway from Aldwych to the point by the side of Waterloo Bridge, where the junction will be made with the Embankment lines. The work on this portion of the subway is, however, being rapidly pushed ahead, and every hope is entertained that traffic may be commenced by the end of March.

It will be remembered that powers were not obtained for the construction of the whole of the lines involved in the scheme of linking up the northern and southern systems until the passing of the L.C.C. Tramways Act of 1906, although the Act of 1902 authorised the construction of the portion of the subway under Kingsway. The map in Fig. 1 shows the position of the subway with reference to the other lines. Further details of the Aldwych-Embankment section of the subway are given in the plan in Fig. 2. The length of the curved tunnel under Aldwych was constructed at the same time as the Kingsway subway, and was used partly for the cross-over in connection with what has hitherto formed the terminal station. A further part of this tunnel was laid with a temporary single track, and used for the storage of cars, and here a plough pit and an inclined repair pit were provided. The permanent concrete work under the temporary tracks, however, was of a form arranged to take the double track and conduits which were eventually to be laid. As the repair pit was made in the centre of the tunnel, and partly by raising the track rails, the removal of the temporary work to permit of the new double track being laid on the permanent foundations is a comparatively simple matter. This part of the subway, following the curve of Aldwych, and sloping down at a moderate gradient to the Strand, is, generally speaking, of similar construction to the Kingsway portion with both tracks in the same tunnel, and, together with the pipe subways with which it is flanked like the Kingsway subway, formed a part

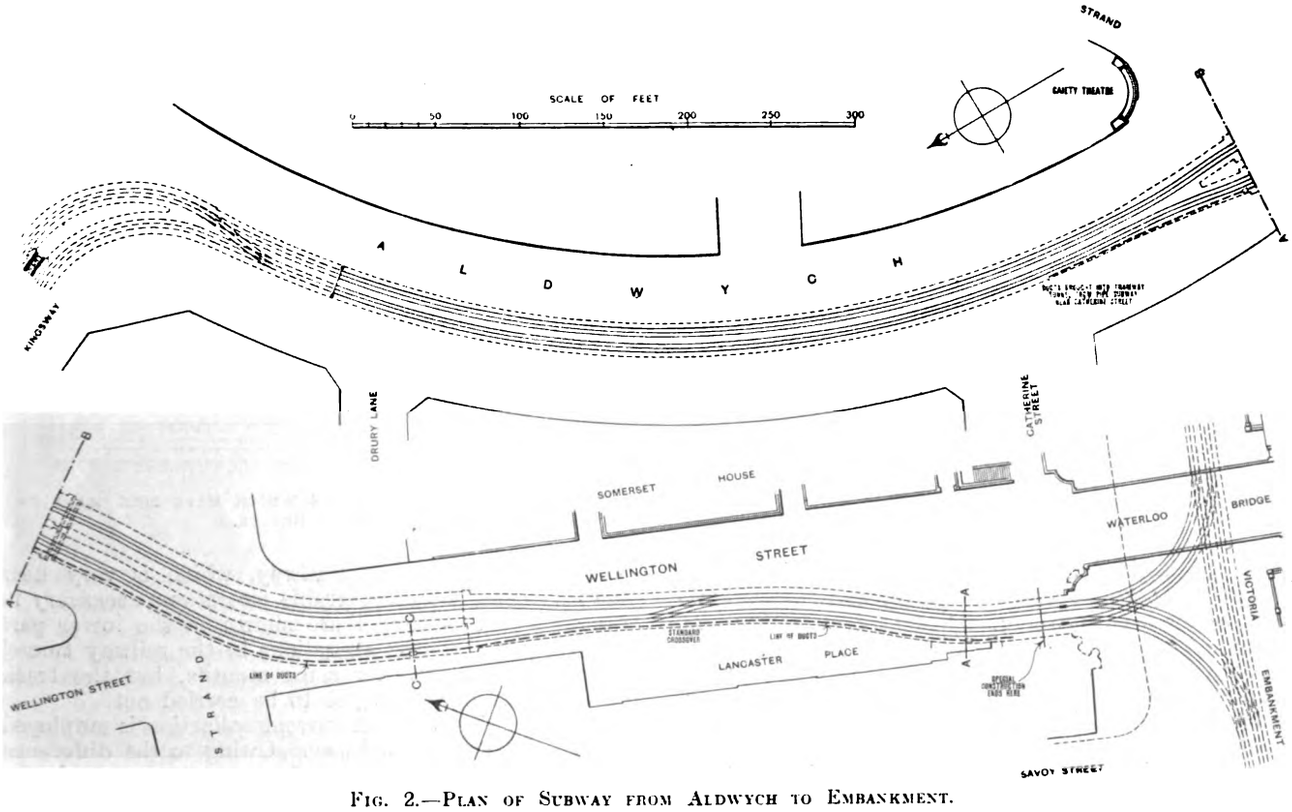

FIG. 2.—PLAN OF SUBWAY FROM ALDWYCH TO EMBANKMENT.

D

Digitized by Google

of the construction of the new thoroughfare. The laying of the new double track is now in progress.

In the second portion of the subway, commencing at the junction of Aldwych and the Strand, the two tracks are placed in separate tunnels, and cast-iron circular tunnel construction similar to that of the "tube" railways has been employed. These tubes were driven with shields in the usual way, and no particular difficulties were encountered in their construction. They

supporting Wellington Street is being cut away. The accomplishment of this part of the work has offered some engineering difficulties, but good progress towards completion has now been made. The alterations to the stone pillars, &c., by the side of Waterloo Bridge for the formation of the entrance arch are indicated in plan in Fig. 3, which shows also the arrangement of the junction with existing Embankment lines. Here the tracks, as they cross the road, will pass over the

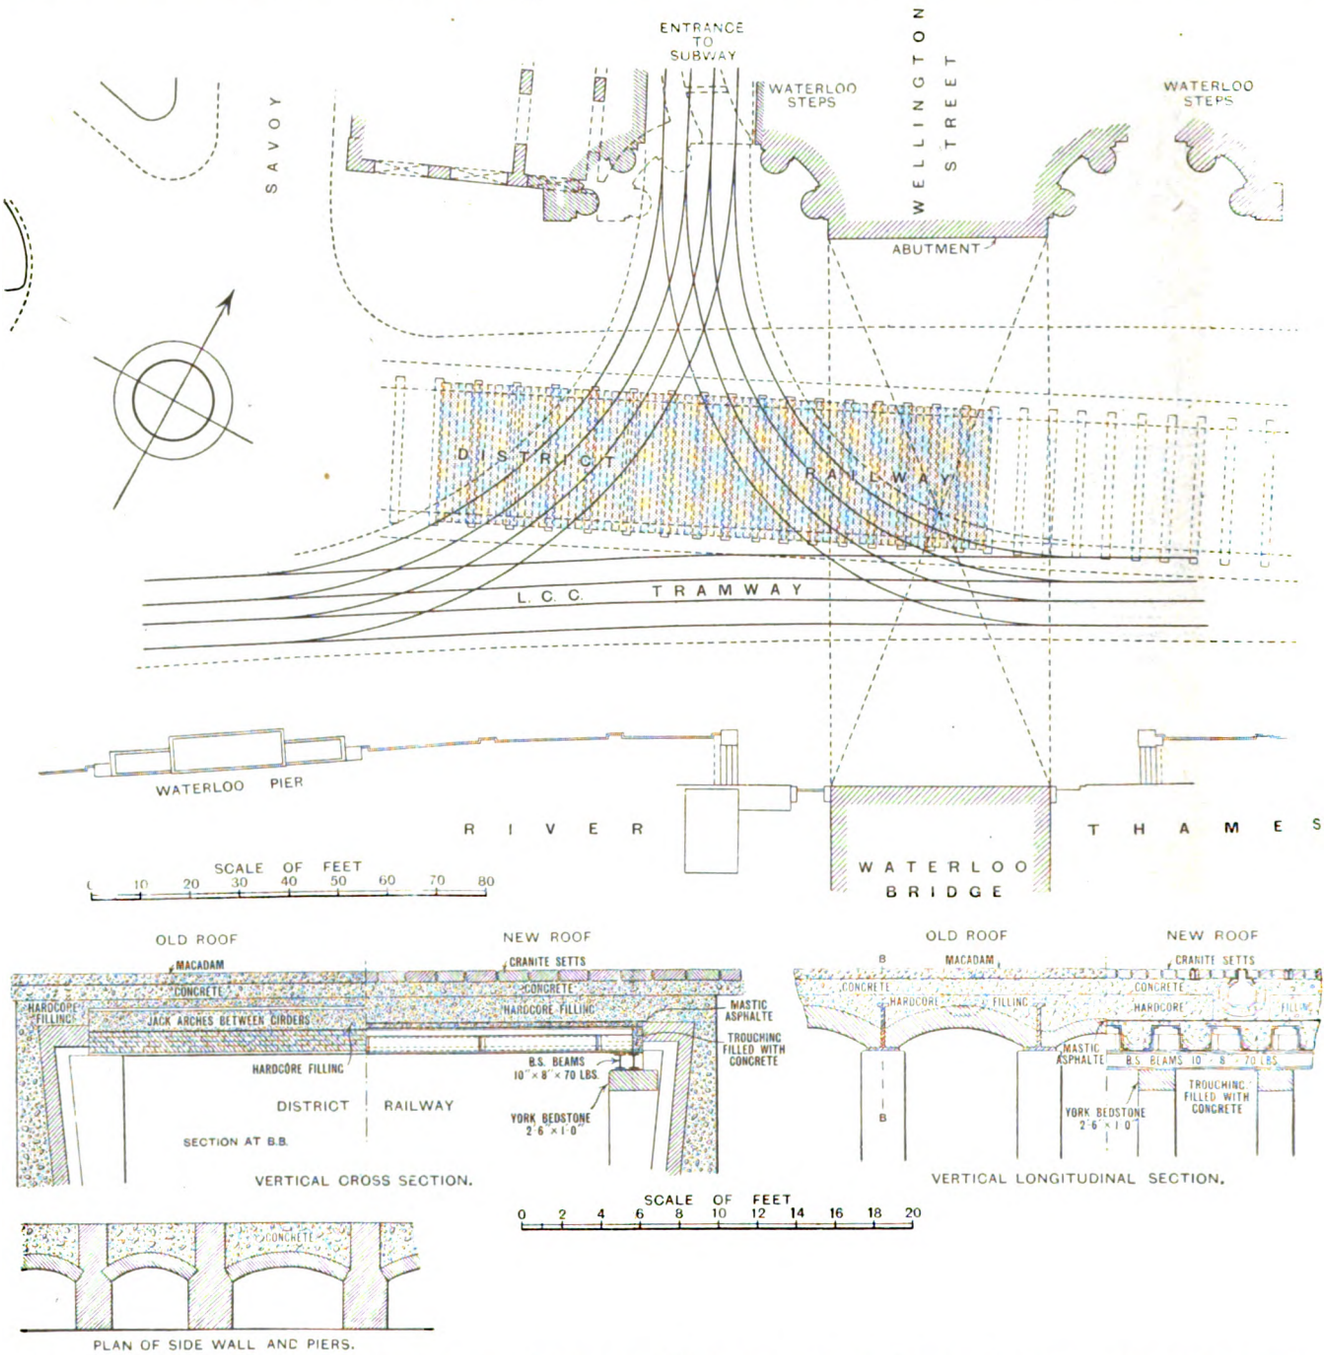

Fig. 3.—Plan and Sections at Junction with Embankment Tramways, showing Alterations which have been made in the District Railway Tunnel Roof and the Stonework by Waterloo Bridge.

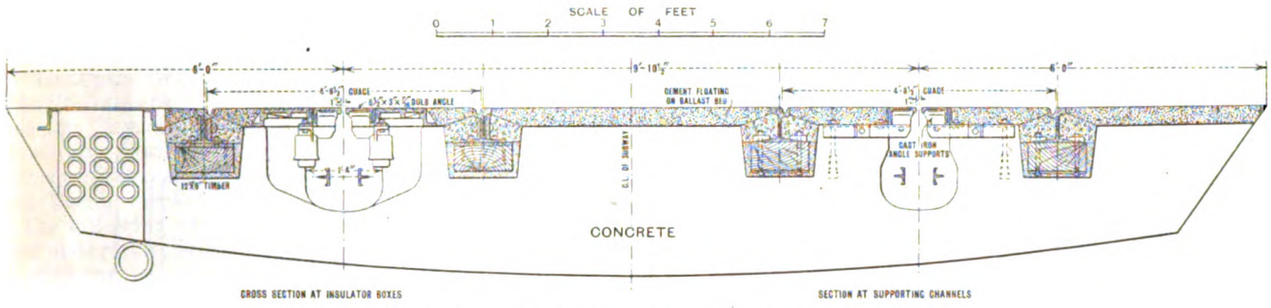
are of 14 ft. 11 in. diameter from iron to iron, both on straight portions and on curves, and this is sufficient to allow everywhere a clearance of 2 ft. round the cars that will be employed. This form of tunnel is continued across the Strand and a short distance down Wellington Street, but the rest of the subway as far as the opening on to the Embankment is all double-track tunnel and steel-work construction with cross-girders is employed. For the insertion of these girders a good deal of the brick arch construction



tunnel of the District Railway, which is very near the surface. The considerable alterations necessary in the roof of this tunnel are shown in the lower part of the figure. These alterations in the railway tunnel have been complete for some months, but the track and conduit work has yet to be carried out.

The conduit system of current collection is employed in the whole of the subway. Owing to the difference in the conditions in a tunnel reserved exclusively for tramways from those prevalent on a road where general

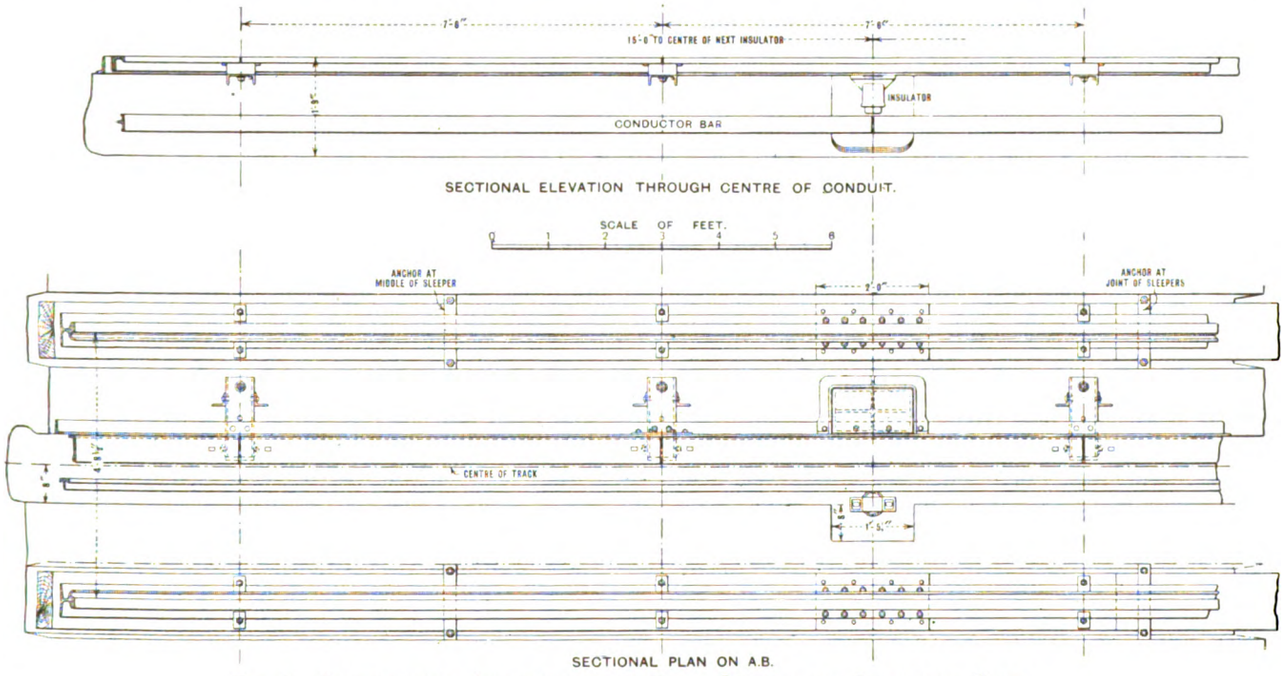
Digitized by Google

vehicular traffic is also present, it has been possible to adopt a design of conduit somewhat different from the standard arrangement employed elsewhere on the London County Council tramway system. The standard road conduit construction as adopted on the Embankment was described at some length in Electrical Engineering, Vol. I., page 9, and it is unnecessary to repeat here the features of its design.

A good idea of the arrangement of the track and conduit in the double-track portions of the subway is obtained from Fig. 4. It will be noticed that, owing to the space between the track rails not being required to take the weight of ordinary traffic, not only have the heavy cast-iron yokes which are such a prominent feature of the standard construction been done away with, but the rigid slot rails are replaced by iron "bulb angle" sections, laid in short lengths, and easily removable, so that the whole conduit is a very great deal more accessible. These bulb angles at each side of the slot, and shown in section in Fig. 4, are laid in 7 ft. 6 in. lengths, and rest at each end on special shaped castings, carried by and bolted to short channel-iron cantilevers, embedded in the concrete, and held down by Lewis bolts. Additional anchoring of these cantilevers in a direction across the track is obtained by short angle iron anchor pieces rivetted to their sides. The positions of these and of the supporting cantilevers themselves are shown more clearly in Fig. 6, which is a plan of a portion of this type of track. The fixed angle bars at either side of the removable bulb angles are also carried on the cantilevers, and serve to hold the slot to gauge, and at the same time as curbs to the concrete. These are laid in 30-ft. lengths and jointed by means of fish-plates. Some further details of the arrangement of the castings which support the ends of the bulb angle sections are shown in Fig. 6, from which it will be noticed that they are cast with a ridge fitting between the ends of adjacent sections which prevents creeping or end-play. The ends of the bulb-angle sections are chamfered off to avoid any possibility of the plough fouling in its passage. The arrangement of the insulator boxes, which occur every 15 ft., is indicated in the left-hand part of Fig. 4, and in greater detail in Fig. 7. The insulators themselves are not quite of the standard pattern as employed on the surface lines, as they are bolted to the continuous-angle irons above them, instead of being attached by means of a bracket on the side of the insulator to the flange of the slot-rail. The covers of the insulator boxes are of a simpler and lighter form than in the standard construction for road work. The running rails are supported on 12 in. by 6 in. longitudinal timbers of pitch pine, to which they are bolted down by means of clips. Special anchor-plates are used under the joints.

CROSS SECTION SHOWING ARRANGEMENT OF TRACKS IN DOUBLE TUNNELS.
THROUGH A.A.

Fig. 4.—Section of Track and Conduit in Double Track Portion of Subway.



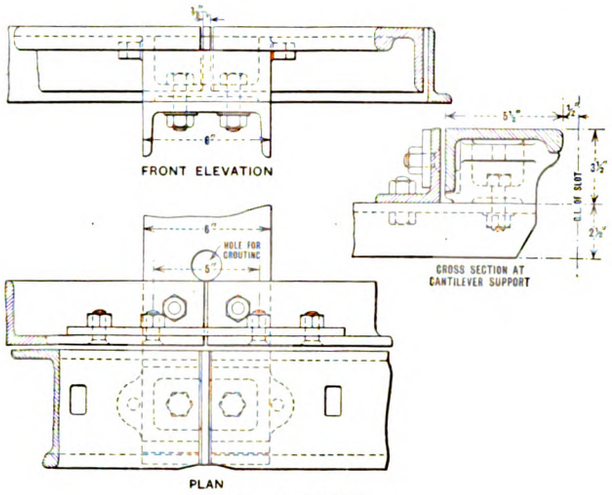


Fig. 5.—Plan showing Arrangement of Track Conduit and Insulation Boxes.

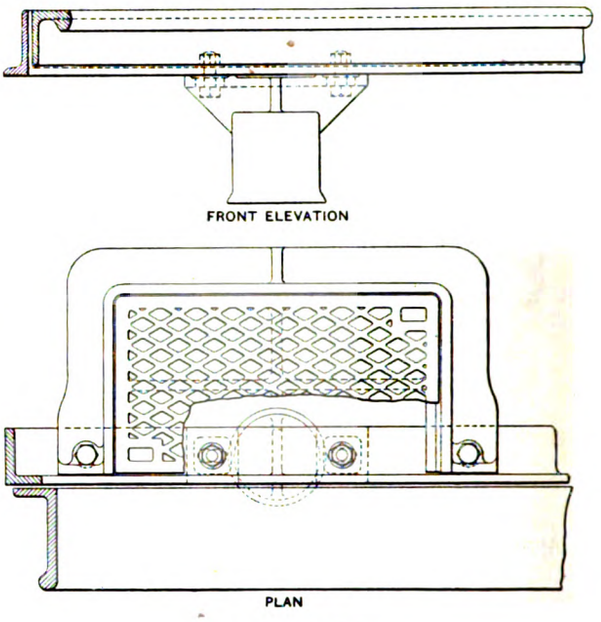
The tramway construction in the short sections of tube tunnel is shown in Fig. 8, and is similar to the

Digitized by Google

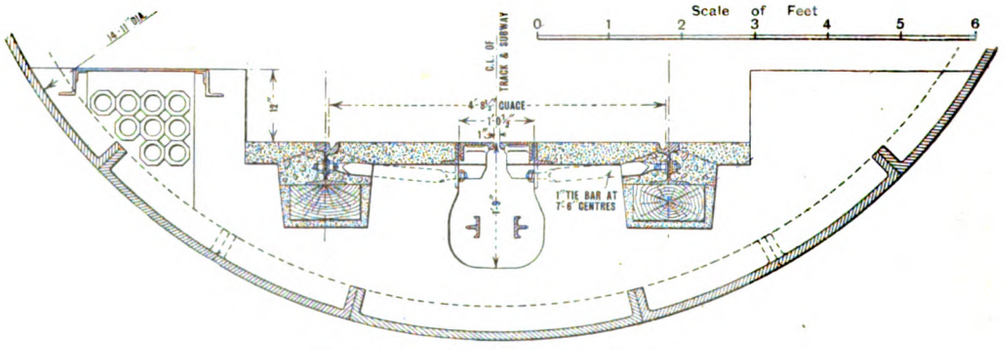
construction in the double tunnel. The figure shows how the concrete work is brought up at each side, above the level of the track, to form continuous platforms, and the arrangement of the cable ducts on one side. Owing to the limited space in the tunnel, it is only practicable to find room for the cable ducts by raising the level of the platforms above the



Scale—1/8th full size.

Fig. 6.—Details of Bulb-angle Supports.

track, but the additional advantage of having continuous platform upon which there was room to walk on both sides of the track led to the same arrangement being adopted on the opposite side. In part of the double-track tunnel the cables are carried in ducts at the side below the level of the track, as shown in Fig. 4, but in the case of the portion under Aldwych they are run in the separate pipe and cable subway alongside the tramway tunnel. As shown in the plan, special castings are used to connect up the standard slot rails with the bulb angle construction described above.



The whole of the track and conduit equipment, and

Scale—1/10th full size.

Fig. 7.—Details of Insulator Box.

also the construction of the subway, was carried out by the Works Department of the London County Council to the designs and under the direction of Mr. Maurice Fitzmaurice, C.M.G., Chief Engineer to the Council, while the laying of the cables and other electrical details are under the supervision of Mr. A. L. C.

CROSS SECTION OF TRACK IN SINGLE TUNNEL THROUGH C.C.

Fig. 8.—Section of Track and Conduit in Single Track Tube Portions of Subway.

a large part of this tube section of the tunnel is on a curve, and special care has been taken in the accurate cutting of the ends of the longitudinal timber sleepers and jointing them together.

In the design of the special form of construction for this work, use was made wherever possible of standard sections, and this, combined with the simplicity of the arrangement, has made the cost compare very favourably with that of the standard equipment. There is a short section just at the entrance of the tunnel at the Embankment, where the standard construction with cast-iron yokes has been employed, and the cross-over road just inside the tunnel entrance is also of the standard conduit construction. There are thus one or two points where transition is effected from the standard to the special construction, and here

Fell, Chief Officer of Tramways, who will also be responsible for the traffic arrangements.

In conclusion, we should express our thanks to these gentlemen, and also to their representatives, for having given us facilities for the preparation of this article, and for the drawings placed at our disposal, from a selection of which the accompanying illustrations have been prepared.

The Electrical Exhibition.—The Manchester Corporation has agreed to permit the use of Platt's Fields for the electrical exhibition to be held in Manchester in October. The use of the ground will be allowed free of rent. Temporary buildings will be constructed, and there is more than sufficient ground for extensions of the building to any size that will be necessary for the purpose. The site lies on a tramway route, and is close to a sub-station of the Corporation electricity department.

THE ACCOUNTS OF THE CHARING CROSS, WEST-END, AND CITY ELECTRICITY SUPPLY COMPANY

IN considering the past year's working of the Charing Cross, West End, and City Electricity Supply Company, it is of some interest to compare the results in the West End and City districts, which are practically two independent undertakings carried on by the same company. As is well known, the West End area is supplied principally from the original generating station at Lambeth, through sub-stations at Maiden Lane, Short's Gardens, St. Martin's Lane, and Green Park; and the City area is supplied mainly from the newer generating station at Bow, through sub-stations at Fenchurch Street, Upper Thames Street, Ludgate Hill, and Beech Street.

The following table gives an idea of the size of the two undertakings, and the growth of the load during recent years:—

	1905.	1906.	1907.
Distributing mains laid—			
In West-end ... ... miles	273	278	280
In City ... ... ,,	229	230	231
Trunk mains inter-connecting stations and substations ... ... miles	112	113	113
Total connections in equivalent 8 c.-p. lamps—			
West-end	453,285	510,589	538,964
City	371,209	412,684	454,757
Motors connected (included in above totals)—			
Total for both areas ... ... B.H.P.	8,000	9,810	11,109

The connections at the close of last year were made up as follows:—

		8 c.p. (30 watt) lamps.
West-end ...	Lighting	391,201
	Heating	10,238
	Power	137,525 (5,501 h.p.)
	Total	**538,964**
City	Lighting	287,787
	Heating	26,770
	Power	140,200 (5,608 h.p.)
	Total	**454,757**
Total for both undertakings		**993,721**

The accounts of the West End and City undertakings are kept separately, but it is not possible to obtain detailed figures accurately analysing the costs in pence per unit sold for each division separately on account of the fact that in both cases a portion of the electrical energy distributed was purchased "in bulk" from the other undertaking. The units sold and generated by each undertaking do not correspond, so that simply to divide the costs of the units sold in each case does not give correct figures.

The units generated and sold by the two undertakings for the year ended December 31st, 1907, are shown, together with particulars of load factor, &c., below:—

	West-end undertaking.	City undertaking.
Units sold for private lighting and power	9,885,086	8,603,741
,, public lighting	452,647	
,, in bulk	576,064	9,567,690
Total units sold	10,913,797	18,172,431
Units used on works and in transmission	4,233,994	4,022,247
Total units accounted for	15,137,791	22,194,678
Units bought in bulk	9,568,690	576,064
Units generated	5,569,101	21,618,614
Total units sold to consumers ...	18,488,827	
Maximum demand load factor ...	5,681 kw.	10,849 kw.

The expenses for each undertaking and the costs per unit sold to consumers for the combined undertakings are given below:—

Generating costs.	West-end. £	City. £	Combined. £	Pence per unit.
Coal	8,349	24,532	32,881	0·428
Oil, waste, water, stores, &c. ...	350	900	1,250	0·016
Salaries and wages	6,801	8,799	15,600	0·203
Repairs and maintenance ..	3,488	6,925	10,413	0·135
Total generating costs ...	**18,988**	**41,156**	**60,144**	**0·782**
Distributing costs.				
Salaries and wages	412	268	680	0·009
Repairs and maintenance ...	5,939	3,732	9,671	0·125
Wayleaves and licences	1,139	147	1,286	0·017
Total works cost	**26,478**	**45,303**	**7,781**	**0·933**
Management expenses, &c.				
Rents, rates, and insurance ...	12,502	9,370	21,872	0·283
Salaries, fees, and establishment charges	6,096	6,481	12,517	0·163
Law, parliamentary, and other charges	974	1,200	2,174	0·028
Depreciation	11,000	—	11,000	0·143
Total, excluding capital charges	**56,990**	**62,354**	**119,344**	**1·550**

In the case of the West End undertaking, the expenditure as analysed above amounted to £56,990 (including £11,000 for depreciation), and £23,124 was paid for current purchased in bulk. The total receipts amounted to £131,920. To the balance of £51,806, last year's balance of £4,575 and interest amounting to £3,472 must be added, giving £59,853, of which £17,829 was absorbed by interest on debentures, leaving a final balance of £42,024 available for dividends.

Treating the accounts for the City undertaking in a similar way, we find a total expenditure of £63,748 (including £1,395 for current purchased in bulk), and receipts amounting to £118,543, giving a balance of £54,795, of which interest absorbed £30,133, leaving £24,662, out of which £18,000 was paid in dividends on preference stock.

The capital expenditure of the two undertakings up to December 31st, 1907, is shown below:—

West End Undertaking.

	£
Purchase of Station mains, &c., and acquisition of Rights	110,745
Additional Expenditure on—	
Land and Buildings	168,417

A DIRECTIVE SYSTEM OF WIRELESS TELEGRAPHY

By E. Bellini and A. Tosi

(*Translated and Communicated by* L. H. WALTER.)

IN a previous article by the same authors (ELECTRICAL ENGINEERING, Vol. II., p. 771), a directive system of wireless telegraphy was described, having an aërial system in the form of closed oscillatory circuits; and diagrams were published, together with particulars of some of the results obtained. The principle of an apparatus by means of which, using fixed and invariable aërial circuits, the direction of communication could be varied, was also briefly indicated. In the present article it is proposed to treat in a more detailed manner the theory and construction of the instruments above referred to, and to which the name of radio-goniometers has been given by the authors.

Radio-goniometer for Reception.—The points AA_1 and BB_1 (Fig. 1) represent the lower ends of the two closed

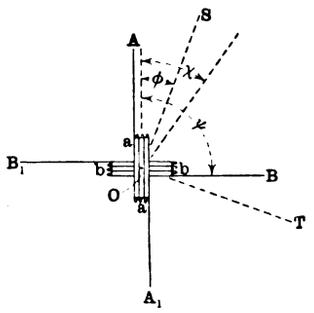

FIG. 1.

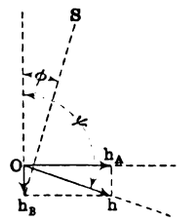

FIG. 2.

oscillatory circuits, which are at right angles to one another. These circuits are joined respectively to the equal and similar windings *aa* and *bb*, which are also mutually perpendicular, the plane of each winding being coincident with the plane of that closed circuit to which it is connected.

Let *S* represent a transmitting station whose direction makes an angle ϕ with the axis *OA*. The electromotive forces, ϵ_A and ϵ_B, respectively generated in the aërial circuits AA_1 and BB_1 by the electromagnetic field set up by the station *S*, will have (as has been shown in the previous article) the instantaneous values represented by the following expressions:—

$$\epsilon_A = Ee^{-\alpha t} \sin mt \cos \phi,$$

$$\epsilon_B = Ee^{-\alpha t} \sin mt \sin \phi,$$

where *E* represents the maximum amplitude of the electromotive force which would be produced in one of the two circuits if the transmitting station *S* were situated in its plane, and α is the damping factor of the oscillations.

Since the two circuits are tuned to the same wavelength, currents are set up in them having the instantaneous values:—

$$i_A = Ie^{-\alpha t} \sin mt \cos \phi,$$

$$i_B = Ie^{-\alpha t} \sin mt \sin \phi.$$

These currents in flowing through the windings *aa* and *bb* set up at the centre of the latter two damped oscillatory magnetic fields having the instantaneous values:—

$$h_A = He^{-\alpha t} \sin mt \cos \phi,$$

$$h_B = -He^{-\alpha t} \sin mt \sin \phi.$$

These fields, directed normal to the planes of the corresponding windings, are indicated by h_A and h_B in Fig. 2. It follows that the resultant field *h* at the centre of the windings will have the value:—

$$h = He^{-\alpha t} \sin mt,$$

which is thus independent of the angle ϕ, that is, of the position or bearing of the transmitting station *S*. The direction of the said field makes an angle ψ with the axis *OA*, which is defined by the relation

$$\tan \psi = h_A/h_B = -\cot \phi.$$

This signifies that the direction of *h* will be perpendicular to that of the transmitting station. It hence follows that if at the centre of the windings *aa* and *bb* there be suitably placed a very small secondary winding—rotatable on the intersecting axis of their planes and joined to a detector as well as being tuned to the waves emitted by the station *S*—the electromotive force induced in the secondary will have the instantaneous value:—

$$\epsilon_i = E_i e^{-\alpha t} \cos mt \sin (\psi - \chi) \ldots\ldots\ldots (1)$$

Here χ is the angle formed by the plane of the winding with the axis *OA*. The maximum of ϵ_i with reference to χ will be obtained when

$$\psi - \chi = 90^\circ \text{ or } \chi = \psi - 90^\circ = \phi.$$

Hence the maximum intensity of reception will also be obtained when the plane of the secondary winding is perpendicular to the resultant magnetic field *h*, that is, when the plane of this winding is in line with the transmitting station *S*. The intensity of the reception is therefore related by a simple harmonic function with the angle through which the secondary winding has to be turned. In consequence, if there be rigidly attached to the secondary winding a pointer movable over a graduated scale suitably oriented, one can determine the direction of the transmitting station *S*. With a view to obtaining indications of the greatest accuracy, it is essential that the secondary winding be very small as compared with the primary windings. As a matter of fact, were it otherwise the relation between the angle ϕ and the position of the secondary winding which gives the maximum reception, or zero reception, would be represented by a function so complicated that it could not be regarded as a practical solution. But, on the other hand, too small a secondary winding would result in an excessively loose coupling between the primaries and the secondary, which would greatly reduce the sensitiveness of the apparatus. On this account it is necessary to give the apparatus such a form that, without diminishing the sensitiveness, it is possible to secure the variation of intensity of the reception according to the sine law.

Two solutions of this problem are available. The first is based upon the properties of the magnetic field produced in the interior of a spherical winding traversed by a continuous current. Under these conditions the magnetic field set up in the interior is uniform, and has a constant direction parallel to the polar axis of the winding. If in the interior of this spherical winding there be suitably placed another, movable winding of arbitrary form and dimensions (Fig. 3), the magnetic flux which traverses the internal winding will vary as the sine of the angle made by its plane with the line *AB*. The movable winding can even be placed outside the spherical one, with the same results and without sensible error, provided the air space between the windings be sufficiently small. The coefficient of mutual

Digitized by Google

inductance between the two windings will vary proportionally as sin γ. If one of the two windings—the exterior one, for example—be traversed by a damped sinusoidal oscillatory current $i_1 = Ie^{-at} \sin mt$, the electromotive force developed in the second winding will have the value:—

$$\epsilon_i = E_i e^{-at} \cos mt \sin \gamma.$$

This expression is equal to (1). It thus follows that if in the space enclosed by the windings of Fig. 1 there be placed a spherical winding which is closely embraced by the primaries *aa* and *bb*, a magnetic coupling between the two circuits is secured which may be as close as possible, and the sine law of variation of the induced electromotive force will always hold. The second solution has been worked out with a view to avoiding the complicated construction which the use of spherical windings involves. For this reason the secondary

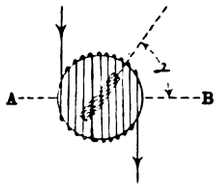

Fig. 3.

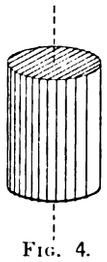

Fig. 4.

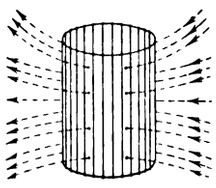

Fig. 5.

winding has been given a cylindrical form, and the turns have been wound on perpendicularly to the circular bases of the cylinder, as is shown in Fig. 4.

Owing to the great analytical complexity, it is impossible to calculate the value and direction for each interior point of a cylindrical winding, of the magnetic field set up by a current passing through such winding; but one can assume that the lines of force follow as near as can be the course outlined in Fig. 5. Since the vertical components of the magnetic lines do not create any flux, one has only to consider the horizontal components lying in the different right sections of the cylinder. It is evident that owing to the special construction of the cylindrical winding, the horizontal components of the magnetic lines of any right section will be equidistant and parallel to the polar axis of the winding; but the number of such lines of force will be different according to the section. It results that the magnetic flux across a rectangular winding, which closely surrounds the cylindrical winding, will be proportional to the sine of the angle that its plane makes with the polar axis of the cylindrical winding. For this reason the windings have been constructed in the manner shown in Fig. 6.

The adjustment of the oscillation constant of the two primary circuits should be effected by altering in an equal manner the number of primary turns, at the same time preserving the symmetry of each primary with respect to the axis of the instrument; and, further, this operation should be capable of being carried out very rapidly. This has been accomplished by the use of the device shown in Fig. 6. The turns of the two primaries, which cover almost the whole surface of the cylinder, are of silk-covered copper wire, the silk covering being removed from the lower end of the vertical part of each turn, the bared portion thus constituting an annular strip, 1 centimetre wide, of juxtaposed wires, the ends of the windings being insulated. Two diametrically opposite movable silver brushes are in contact with the bared portion of each winding, the two pairs of brushes, *aa* and *bb*, being connected respectively to the two aërial circuits. The four brushes, placed at the four extremities of two mutually perpendicular diameters, are fixed to a slate disc, movable around the axis of the instrument. Referring to Fig. 6, the winding $cAd\ r\ A_1 n$ is bared between Ad and $A_1 n$, and the winding $uBs\ m\ B_1 e$ between Bs and $B_1 e$. By turning the brushes in the direction of the arrow, the number of turns in circuit is increased equally in the two windings. When the brushes are in the position *dn* and *se*, all the turns are in circuit. The number of turns in the secondary winding is fixed, the ends of the winding being connected to two contact-rings upon which two further brushes bear, the latter being fastened to the base and connected to two terminals. Between these two terminals the detector is inserted, across a variable capacity and a variable inductance. By altering these latter one can vary the oscillation constant of the secondary circuit and the degree of magnetic coupling between the primary circuits and the secondary.

From the description of the radio-goniometer already given, it follows that in order to use it for locating the waves sent out by a station whose bearing and wave-length are both unknown, it is necessary to simultaneously carry out two different operations; that is to say, (1) to tune the apparatus to the wave-length, and (2) to set the movable winding in the direction of the unknown station; and reception is obtained only after both these operations have been accomplished. The reception would then be a function of two simultaneous adjustments, which is neither easy nor practical. For this reason the adjustment of the radio-goniometer has been reduced to two independent operations: first, the tuning to the wave-length of the signals to be received; and second, the orientation of the secondary in the plane of the transmitter station. This result is arrived at in the following manner:—

In the case of a symmetrical closed oscillatory circuit, the lowest middle point is the seat of a potential node; it is thus possible to earth the circuit at this point without causing any change in its behaviour. If one-half of such an aërial circuit be detached and one point of the winding earthed, the other half of the aërial circuit becomes an ordinary symmetrical antenna. To ensure that the frequency of this antenna is the same as that of the original closed oscillatory circuit, it is necessary that the earth connection should be made at a potential node; that is, the mid-point of the winding.

This method of reasoning has been applied to the radio-goniometer as follows:—The middle point of the

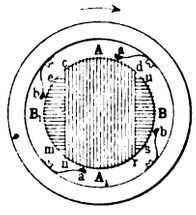

Fig. 6.

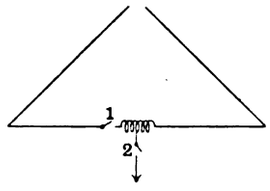

Fig. 7.

two primary windings (Fig. 7) can be earthed by the switch 2, and one-half of the aërial circuit which is connected to the winding can be cut out by means of the switch 1. These operations having been completed, and the secondary winding turned so that it is parallel to the primary in question, the radio-goniometer is reduced to an ordinary receiving jigger or transformer, whose primary is connected to a vertical antenna and to earth—an arrangement which permits of the tuning to the wave-length of the unknown transmitting station being carried out without troubling about its position. But since the tune of this symmetrical antenna is the same as that of the closed oscillatory circuit, by merely opening switch 2 and closing 1 the radio-goniometer is perfectly tuned for the directive reception. After this it only remains to turn the secondary winding until the reception is a maximum.

Fig. 10 shows the receiving radio-goniometer of average size for wave-lengths lying between about 300 and 800 metres. The ends of the two oscillatory circuits

Digitized by Google

which constitute the aërial structure of the system are connected to the terminals *aa* and *bb*, each pair of terminals being joined up to one pair of the diametrically opposite brushes. (One such brush is shown at *c*.) The two primaries, mutually perpendicular, are wound—the one between the pillars p_2 p_3, and the other between the pillars p_1 p_4. The supporting end-discs for the windings are of slate, the vertical portion of the turns being free and unsupported. The bared region of the winding, over which the brushes make contact, is sustained by the thickness of the lower disc. The switch-arm *d* effects the simultaneous operations of the switches 1 and 2 of Fig. 7.

The twenty-five turns of the secondary, internal to the primary, are wound on an ebonite cylinder having a metal spindle, the two halves of which are insulated from one another. The ends of the windings are joined respectively to the upper and lower half of the spindle, and through two brushes (not shown in the figure) to the terminals *ss*. To the upper end of the spindle a milled head *r* and double pointer are rigidly attached. The one pointer *ff* is black, and parallel to the polar axis; the other *gg* is white, and perpendicular to the black one. The two pointers move over a graduated circular dial, which indicates the position of the transmitting station. The milled-head *m* enables one to turn the slate disc supporting the silver brushes *cc* provided for varying the number of primary turns. The terminals *ss* are joined up to an electrolytic detector across a variable capacity and variable inductance as already mentioned. The exterior dimensions of the instrument are:—Height, 28 centimetres; width, 24 × 24 centimetres.

With this apparatus the bearings have been determined of a number of stations in the English Channel, in France, England, &c., whose wave-lengths were within the range above mentioned. Using the same radio-goniometer, reception from stations using very long waves, such as the Eiffel Tower, Poldhu, Clifden, Nordeich, was effected by inserting in the two aërials four equal inductances, symmetrically placed with reference to the radio-goniometer, two in each oscillatory circuit. The reception under these conditions was obviously not as good as it might have been, owing to the coupling of the primaries with the secondary being too loose. On this account a larger size of apparatus has been constructed with which very good reception from the long-wave stations has been achieved. The exactitude with which the bearing of a transmitting station can be determined is quite remarkable, an accuracy of 1° being readily obtained after repeating once or twice the process of taking the limiting angles at which reception ceases; and this accuracy is independent of the azimuth of the transmitting station. The determination of the actual position, not merely the bearing, of a station by the intersection method has confirmed the great exactitude obtainable by the use of the radio-goniometer. The azimuths of the same station, determined from Dieppe and from Havre, always intersected at practically the exact spot where the station was situated.

So far as the zone, within which one is certain of not being troubled by transmissions other than the one desired, is concerned, this zone is a function of the azimuth of the other stations, of their distance, and of the intensity and damping of their transmissions. But to give an idea of the independence which is obtained by means of the radio-goniomenter, it is sufficient to refer to experiments made between Dieppe and Havre. In all cases it has been possible to receive clearly at Havre from Dieppe without being troubled by other transmissions; this, however, was in general impossible when the ordinary vertical antenna was employed.

The radio-goniometer for reception can conveniently be used for comparing the strengths of two or more transmissions. Suppose now that the detector employed is one which responds solely to the amplitude of the oscillations. For each transmission the two limiting angles on the radio-goniometer are determined for which the reception ceases. Calling α and β these angles for the one transmission, and γ and δ those for the other, the ratio of the amplitudes of the transmissions will be, according to what has already been given:—

$$\sin \frac{\alpha + \beta}{2} \Big/ \sin \frac{\gamma + \delta}{2}.$$

If the detector is of a type which responds to the total energy received, the preceding ratio is that of the energies emitted by the two different transmissions. This enables one, further, to determine the diagram of the field produced by a directive transmitter station at long distances.

The same means enables one also to determine whether a detector responds to the maximum amplitude or to the energy of the electro-magnetic field. To effect this purpose a directive transmitter station must be available for which the diagram of emitted energy has been determined by means of a thermo-galvanometer or similar instrument. If the detector under consideration, when used at a directive receiver station, gives a diagram similar to that obtained by the thermo-galvanometer, this means that the detector responds to the energy. If, on the other hand, it gives a diagram whose *radii vectores* are proportional to the square roots of the Duddell diagram, the detector responds to the amplitude of the field. If the detector gives an intermediate diagram, this may be taken as indicating that its operation is not clearly defined, and that it depends partly on the energy and partly on the maximum amplitude.

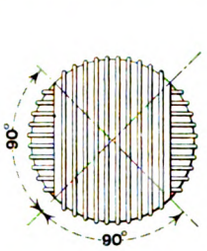

FIG. 8.

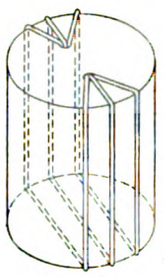

FIG. 9.

Radio-goniometer for Transmitting.—This apparatus is based upon a similar principle to that of the receiving radio-goniometer. Referring to Fig. 1, if in the interior of the two windings *aa* and *bb* there be an oscillatory magnetic field whose direction *OT* is perpendicular to *OS*, and whose equation is $h = He^{-\alpha t} \sin mt$, there will be created in the windings the electromotive forces:—

$$\epsilon_a = Ee^{-\alpha t} \cos mt \sin \psi,$$

$$\epsilon_b = -Ee^{-\alpha t} \cos mt \cos \psi.$$

These will give rise in the aërial circuits to oscillatory currents of proportional intensity; and each aërial will set up an electromagnetic field in space, which field will also vary sinusoidally in space, as has been shown in the first part of this article. These fields (having any direction whatsoever which makes the angle χ with the axis *OA* and at a definite distance) will be represented by the expressions:—

$$m_{A\psi} = Me^{-\alpha t} \cos mt \sin \psi \cos \chi,$$

$$m_{B\psi} = Me^{-\alpha t} \cos mt \cos \psi \sin \chi.$$

The resultant magnetic field at the point considered will be the algebraic sum of the component fields:—

$$m = Me^{-\alpha t} \cos m\,t\,(\sin \psi \cos \chi - \cos \psi \sin \chi),$$

$$= Me^{-\alpha t} \cos mt \sin (\psi - \chi).$$

Digitized by Google

The maximum value of the field is obtained when between the angles ψ and χ the relation

$$\psi - \chi = 90^\circ \text{ or } \chi = \psi - 90^\circ = \phi$$

exists. This signifies that the maximum intensity of transmission occurs in the direction perpendicular to the magnetic field which excites the two windings *aa* and *bb*, and that this intensity is independent of the angle ϕ; that is, of the direction of transmission. In consequence, by causing the magnetic exciting field to be turned in a uniform manner, the direction of emission of the waves will turn equally and in the same sense in the horizontal plane.

The transmitting radio-goniometer, like that for receiving, can be made in the spherical or cylindrical form. The cylindrical form was preferred for the reasons already given in the case of the receiving radio-goniometer. The movable winding in the transmitting radio-goniometer forms part of the primary circuit. The magnetic coupling between this circuit and the aërial circuits is of a suitable value, such that the proportionality between the electromotive force and current in the aërial circuits may be obtained. The primary winding consists of three thick wires joined in parallel. This form of winding is necessary in order that the primary of the transformer should have the minimum inductance. The single turn of three wires is put on as shown in Fig. 9, the ten turns (in series) of the secondary winding being shown in Fig. 8. Although the primary winding does not cover the whole surface of the drum, nevertheless the measurements of the current in the aërials and others made at a distance with the aid of the thermo-galvanometer have shown that the partial winding is practically equivalent to the complete winding; and since the latter presented considerable constructional difficulties without any real advantages, the partial winding has been adopted.

The transmitting radio-goniometer can, as in the case of the receiving instrument, be constructed so that waves of different lengths can be emitted. When it is a case of sending signals to a station whose bearing is unknown, or to different stations at the same time, the problem is analogous to that at the receiving station. One solution is obtainable in the following manner:—Referring to Fig. 7, where the winding in the case of transmission represents one of the two secondary circuits, one can convert, by means of the switches 1 and 2, the closed aërial oscillatory circuit into an ordinary antenna. This makes it possible to send signals equally in all directions, and consequently also to the unknown station or to a plurality of stations. When, however, it is desired to use the directive system, one has merely to alter the switches 1 and 2 accordingly, and to set the primary in the direction of the corresponding station.

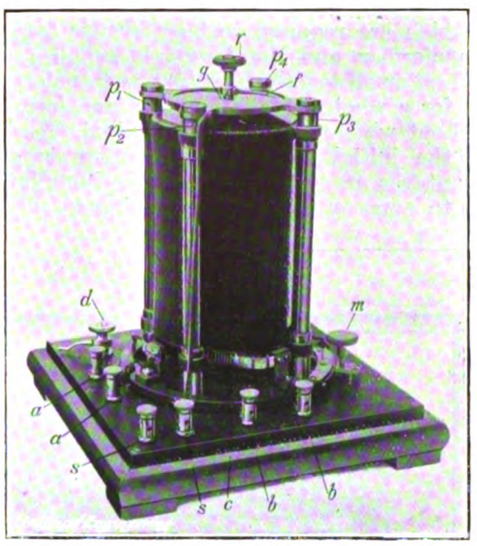

FIG. 10.

One can pass in this manner from the ordinary symmetrical transmission to directed transmission, and *vice versâ*, without its being necessary to touch the tuning in any way; and this for the same reason as was shown in the case of the reception. A divided circle is provided on the transmitting radio-goniometer, and a pointer fixed in this case to the primary winding, so that the latter can be oriented in the different azimuths.

The chief dimensions of the apparatus are:—Height, 50 centimetres; width, 35 × 35 centimetres.

SMALL TRANSFORMERS FOR USE WITH METALLIC FILAMENT LAMPS

THERE are many instaliations where difficulties present themselves in the way of taking full advantage of the very great economies which are offered by the high efficiency of metallic filament lamps as compared with ordinary carbon filament lamps. The principal obstacle is the fact that in a great number of cases metallic filament lamps cannot be obtained for voltages as high as that of the supply circuit available, or can be obtained only in sizes forming an inconveniently large unit of light. It is true that during the last few weeks a 16-candle-power, 100-volt, metallic filament lamp has been placed on the market, and one or two makes of lamps, of a much larger size, however, are being introduced for 200-volt circuits, but it is at comparatively few places that a supply voltage of 100 volts is available, and for 200-volt circuits the unit formed by two 100-volt lamps in series, or by such 200-volt lamps as are already available, is, in general, inconveniently large, especially in the case of existing installations planned for smaller lamps.

Where the supply is alternating, the difficulties can be got over by the use of appropriate transformers for reducing the voltage, and there is no doubt that, with a well-designed transformer, the first cost of the apparatus is soon paid for by the saving obtained by the use of high-efficieny lamps, notwithstanding such losses as there are due to the transformer itself. We cannot but think that if this were more widely realised, the use of metallic filament lamps for ordinary domestic lighting, office lighting, and other purposes, where that 16-candle-power lamp has been the standard, would on alternating-current circuits at any rate largely increase. Already a good deal of attention is being paid by manufacturers to the development of this class of apparatus, and it is the purpose of this article to call attention to a few examples of small transformers designed for this purpose which are at the present time on the market in this country.

Speaking generally, the type of transformer most suited to the purpose is that with a single winding, as it offers advantages both as regards efficiency and first cost. Although they can be used simply as step-down auto-transformers, it is advantageous wherever the nature of the installation allows it to adopt a distributing secondary pressure exactly one-half or one-third of the supply pressure, and connect the transformer as a balancer with the equivalent of a three-wire or four-wire distributor system. As to the secondary pressures which are most suitable, a good deal depends on the exact make of lamp adopted, and the size of lamp best

Digitized by Google

adapted for the installation in question. In many cases 100 volts will be a sufficiently low pressure, but with some makes of lamps a convenient-sized lamp to replace the existing lamps of an installation is not obtainable until 25 volts is reached. There is no doubt, however, that there is some advantage in keeping the voltage fairly low, as the filaments of the lamps are thicker and less fragile.

In installing transformers for this purpose, two different methods of distribution may be adopted: (1) One transformer may be used for each lamp or group of lamps which are required to burn always together, so that transformer and the lamps it supplies may be switched on or off together; or (2) one transformer may be used for a whole installation, the transformer being switched out when no lamps are required. In the first system the initial cost of transformers is greatest; the advantages are, however, that the installation wiring has to carry current corresponding to the normal

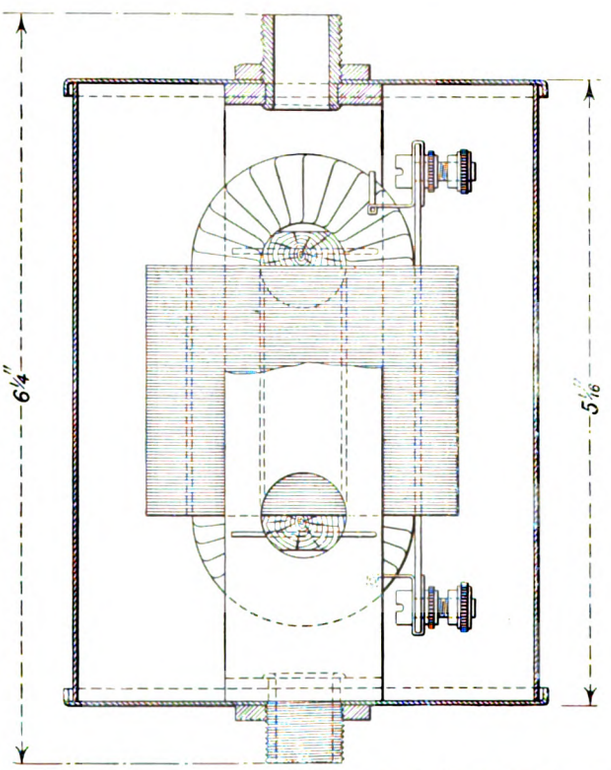

Fig. 1.—Section of Small Westinghouse Transformer for Single Metallic Filament Lamps or Small Groups.

circuit voltage instead of the reduced lamp voltage, and that no losses occur in the transformer when the lamps it supplies are not in use. Further, the transformer is always operating at full load corresponding to its highest efficiency. The second system has the advantage of lower first cost of transformers; on the other hand, the installation wiring must be suitable for carrying the current corresponding to the reduced voltage, and when only a few lamps are in use, the transformer will not be working at its highest efficiency. In arranging installations, therefore, it may often be found advisable to adopt a combination of these two systems, single-lamp transformers being used where it is necessary or convenient to always have the light available without having first to go to the main switch, as, for instance, in bedrooms, cellars, &c.; and the larger transformers for such lamps that are required for certain periods only, so that the switching in or out of the transformers does not cause any inconvenience, as, for instance, in sitting-rooms, shops, &c. With this arrangement the installation can be worked at its highest efficiency, the large transformers being cut out for the greater part of the time, and the cost of the no-load losses—which, although very small, otherwise go on continuously—is eliminated.

As already pointed out, the winding of these transformers with the single winding, and taking the required secondary voltage between one of the line wires and intermediate tapping, enables the same output to be obtained at a smaller cost and with lower losses than is possible with an ordinary two-winding transformer. Thus in all cases where special conditions do not compel the use of electrically separated primary and secondary

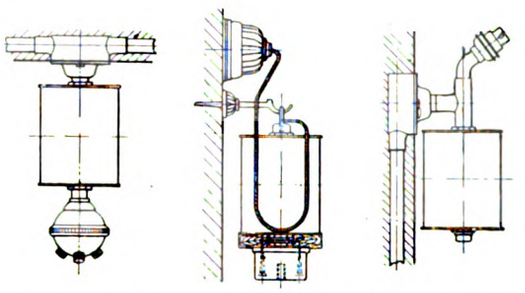

Fig. 2.—Small Westinghouse Auto-transformers for Single Lamps or Groups of Lamps.

circuits, the auto-transformer should be used in preference to that with two separate windings.

A balancing transformer possesses a single winding which is divided by means of tappings with two or more equal parts, each of which supplies a separate circuit. Each of these two circuits, separately controlled, can take approximately the same independent load as an auto-transformer of that ratio with about the same transforming losses. Whenever the distributing conditions permit, the balancer should therefore be used in preference to the auto-transformer. A further advantage of the balancer is that it can supply any number of lamps as long as the difference in load on the circuits having maximum and minimum currents is not larger than the "independent" load mentioned above, which may be termed the "balancing capacity." As the transforming losses remain unaltered, practically any efficiency can therefore be obtained.

As examples of the electrical performance of these

Fig. 3.—Westinghouse Transformer for Metallic Filament Lamp Installations.

types of transformers, a 50-watt, 50-period, 100- to 50-volt auto-transformer has total losses of approximately 4 watts (*i.e.*, an efficiency of 92 per cent.). The same transformer used as a two-circuit balancer with a load of 50 watts on each circuit (*i.e.*, a total load of 100 watts) has an efficiency of 97·6 per cent. An 800-watt, 50-period, 200- to 100-volt auto having an iron loss of 12½ watts has an efficiency of 97 per cent. If the same transformer is used as a two-circuit balancer, having 400 watts load one circuit, and 1,200 watts the other, the losses would remain the same, and the efficiency will be 98·45 per cent. If the two circuits are loaded,

Digitized by Google

each with 800 watts, the efficiency will be 99·2 per cent. At higher frequencies somewhat higher efficiencies will be obtained.

A special line of transformers for the first of these systems of distribution has been developed by the British Westinghouse Electric & Manufacturing Co. A section showing the general construction of this simple design of transformer is shown in Fig. 1, and one or two of the numerous ways in which they can be applied to ordinary fittings are illustrated in Fig. 2.

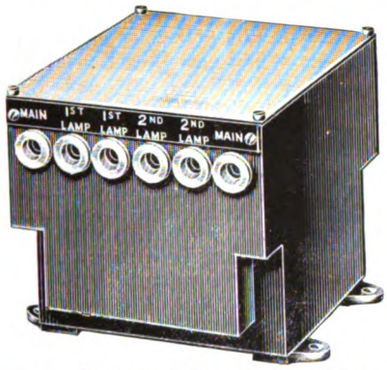

Fig. 4.—Auto-transformer for Metallic Filament Lamps. (General Electric Co.)

The transformer is encased in a sheet-iron cylinder with lids at top and bottom. By loosening one nut the casing can be readily removed, and the screw terminals to which the lamp and line are connected are disclosed. These transformers complete weigh for the various sizes from 5 to 7½ lb.

The transformers already shown in Fig. 1 can also be used for the second of the two systems described above, but as the output ranges only from about 25 to 100 watts, the British Westinghouse Co. has developed the larger type shown in Fig. 3, having capacities ranging from 200 to 2,000 watts. Both types are made for standard ratios of 200 to 100, 200 to 50, 100 to 50, and 100 to 25 volts, both as auto-transformers and balancers, and for different periodicities.

In these transformers, the portion of the windings not enclosed in the laminated iron are protected by end castings through which cable leads are brought out. Lugs are provided on these castings so that the transformers can be mounted in any position. A shell type construction is used with E-shaped laminations, interleaved and clamped so as to enable them to work absolutely

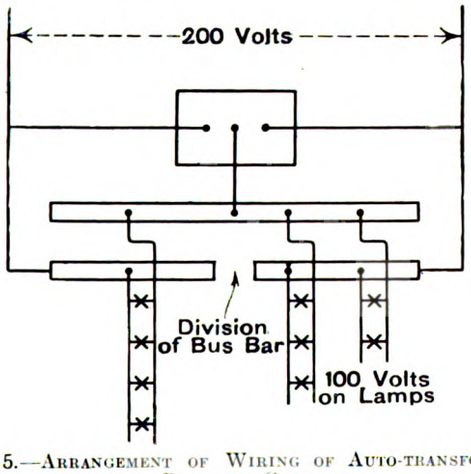

Fig. 5.—Arrangement of Wiring of Auto-transformer for Balanced Circuits.

without noise. These transformers vary in weight from 12 lb. for the 200 watt size to about 27 lb. for 2,000 watts.

Special transformers for metallic filament lamps have also been designed and placed upon the market by the General Electric Co., Ltd., with high all-day efficiency and small open-circuit loss. Fig. 4 shows the general appearance of one pattern of these, which is an auto-transformer with two balanced secondary circuits. This is suitable for use on a 200-220 volt circuit, and gives a secondary output of 100-110 volts, and where it is possible to balance the lamps in a building within 5 or 10 amperes, it will be found that with a transformer of this kind an efficiency of 99 per cent. is readily obtained, and under these circumstances the capacity of such a transformer is almost unlimited, as they only carry the out of balance portion of the load. In addition, the company make transformers from 200-25 volts, and from 100-25 volts, so that small c.p. metallic filament lamps may be used The efficiency of the ½-kw. size wound in this way would be as high as 95 per cent. full load, and over 90 per cent. quarter load, while the open circuit loss on 50 cycles would not exceed 16 watts.

Messrs. Siemens Bros. Dynamo Works, Ltd., have for some years been in a position to supply small transformers in patterns suitable for use both indoors and in the open air for obtaining lower voltages than are commonly available. These were originally designed when the only metallic filament lamp was the osmium lamp, and were for a secondary voltage of 40 volts. The standard arrangement listed is for 110 to 120 volt circuits, and is arranged with two tappings, to be used as a three-part balancing transformer for a four-wire distribution.

A special type of transformer which has been developed for use with the metallic filament lamps by Messrs. W. E. Burnand & Co., of Sheffield, who have for some time specialised in the manufacture of transformers of all kinds. Like most makers, this firm have adopted the auto-transformer in preference to the double-wound type, as being more efficient and cheaper in first cost. They also emphasise the advantage of arranging the transformer as a balancer and grouping the load as evenly as possible on both sides. The influence of the balancing on the efficiency is made clear by the following example, which relates to a 200/100 volt transformer for 18

Fig. 6.—Small Transformer for Metallic Filament Lamps. (Union Electric Co.)

amperes, 75 cycles, with a constant iron loss of 10 watts, connected as a balancer.

	Total loss.	Volts on heavier loaded side.
18 amperes on one side and nothing on the other	41 watts	98½
18 amperes on each side	10 ,,	100
18 amperes on one side and 9 amperes on the other	18 ,,	99¼
10 amperes on one side and 8 amperes on the other	10½ ,,	100

With regard to the arrangement of existing 200-volt installations for these transformers, where the system of wiring permits of its being divided into two or more bunches, of approximately equal current requirements, as, for instance, when supplied from a distribution board, the method shown in Fig. 5 may be adopted. Where a distribution board is used this involves only the cutting of one bus bar, and the removal of one main from the uncut bus bar to the half of the bus bar divided from the other main by the cut, in addition to joining in the transformer as shown. When this system is used only the *difference* between the current taken by the two halves of the bus bar passes through the transformer, and when these are balanced the only loss is the extremely small exciting current taken by the transformer. There is a further small loss in the transformer when the currents of the two halves are not equal, but this is only on whilst the currents are out of balance, and is almost negligible unless the two halves are *much* out of balance, which is a con-

Digitized by Google

dition that seldom obtains for any length of time. Messrs. Burnand have considered the question of voltage regulation very carefully, and have in some cases only listed transformers at less than their rating, so far as ability to stand maximum current is concerned, in order to be able to keep the maximum variation of voltage within 1½ per cent. under extreme conditions. Two types are listed, one of which has a lower iron loss than the other, and in both of these care has been taken to employ non-ageing material, so that the iron losses do not increase with use. Transformers are also made for use where the wiring does not admit of dividing into approximately equal sections, so that it is necessary for the transformer to carry the whole current, the supply being led into one pair of terminals and the lower voltage out of another pair.

The Union Electric Co., Ltd., are also taking up this class of work, and are able to supply not only transformers for a secondary of 110 volts, but also for 25 volts. In designing these transformers, which are of the general form shown in Fig. 6, the object has been kept in view of striking a satisfactory balance between the initial cost and the economic requirements as to efficiency and open-circuit loss. They realise that by using special material of the very highest quality, it is possible to reduce the losses to the lowest, but at the same time the initial cost of the apparatus is considerably increased, and in their opinion the increased efficiency does not compensate for the increased cost. It is thus their object to supply an apparatus of the highest efficiency, compatible with reasonable cost. The 110-volt transformers would be used for Osram lamps of high candle-power, viz., 30-100, and also for use with tantalum

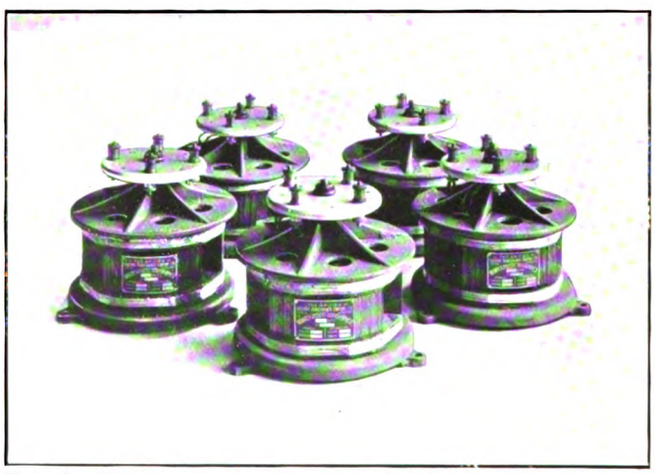

Fig. 7.—Group of Small Berry Transformers for Metallic Filament Lamps. (British Electric Transformer Co.)

lamps, for which this pressure is standard. The transformer giving 25 volts has been introduced, so that Osram lamps of 10 and 16 candle-power may be employed without alterations to the wirings and fittings at present fitted, for, of course, should lamps of perhaps twice or three times the candle-power have to be installed in present fittings, the lighting effect would be spoilt on account of certain places in the rooms being over-lighted.

Messrs. Johnson & Phillips have designed a special series of transformers for the purpose we are considering, and have adopted the following as the standard voltage ratio :—200/100, 200/50, 200/25, 100/50, and 100/25 volts. The standard frequency is 50, but they have also made these transformers for 85, 90, and 100 periods. The cores of these transformers are built up by a special process which reduces any additional iron losses in the clamping plates to a minimum, and it is owing to the careful way in which the laminations are insulated from one another, and to the minute inspection of every detail of manufacture of the core, that they are enabled to guarantee specially low figures for iron loss. The iron is of the very best quality, and similar to that employed in the standard line of transformers which they have lately put on the market. The ageing co-efficient of the iron is very small, and they claim that there is practically no increase in the iron loss as time goes on. The coils are former wound of a special ventilated type, which allows free access to both the core which they surround and to every part of the coils. They are insulated from the core by distance pieces of special material, which act as spacers to allow free ventilation. Finally, the coils and core are assembled and fitted in a cast-iron case of very substantial construction, the lid of the case being removable, so that the transformer is open to inspection. Terminals are provided at the side with leading-out wires, to which the connections are made. The transformers are of the auto-type, as by this means the output as well as efficiency of any given size is very much increased, and the iron loss and volt drop made very much smaller.

The following maximum efficiencies are claimed for the different sizes. The best efficiency is obtained at about three-quarter load :—

Watts.....	500	1000	1500	2000	3000	5000
Efficiency ...	92·5	95·0	95·5	95·8	96·4	97·0

A very simply constructed auto-transformer for use with metallic filament lamps is supplied by Messrs. Ward & Goldstone, of Manchester. These are fully standardised for primary voltages of 250, 220, 200, and 100 volts, and secondary voltages of 110, 100, and 25 volts, in capacities ranging from 250 to 1,750 watts.

The British Electric Transformer Co. have given so much attention to improving the design of transformers of all sizes that we naturally look with interest to the special apparatus for the purpose we are considering manufactured by this firm. As may be seen in Fig. 7, which illustrates a group of these small transformers, the general principle of their construction is the same as for the larger transformers, for which the company has earned so high a reputation. They are manufactured under the Berry Patents, and are insulated and built up in exactly the same way as the largest Berry transformers, for use on circuits of the highest voltages, with radial laminations arranged with ventilating spaces so as to ensure as large a cooling surface for the iron as possible, and as short a length of mean turn as is obtainable for the winding. The efficiencies are kept as high as possible, and special attention is paid to reducing the open circuit loss to a minimum. Transformers can be supplied to any requirements, and it must be realised that the losses and efficiencies given on any transformer are necessarily dependent on the price to be paid for the apparatus. In all cases where the supply voltage does not exceed 250 volts they recommend the use of auto-transformers, and where it is possible to adopt them they supply these with the terminals arranged for use on two or more balanced secondary circuits, in the manner we have already indicated. The transformers are compact and neatly finished, and can be mounted in any position. We understand that the company have anticipated the demand for the particular type of transformer by extensions to their shops laid out so as to be specially suitable for this class of work.

Messrs. Drake & Gorham, who have always been to the fore where metallic filament lamps are concerned, have made arrangements for the supply of a thoroughly well-made transformer for this purpose. These transformers are made in three sizes, namely, for maximum outputs of 1,500, 750, and 500 watts. The winding of the transformer is split into two circuits, each of which is one-half the line voltage. The highest efficiency, that is to say, the least loss, is obtained by dividing the lamps equally between the two legs; if this is done there will be a balanced load, and the only loss in the transformer will be the open circuit loss. The secondary E.M.F. will not be affected by an unequal number of lamps being connected to the two legs of the transformer, either of which may be fully or partially loaded or not at all, but for the reason mentioned above it is better to divide the circuits up so that there may be as near as possible the same load on each leg. The open circuit losses of the three sizes are 16·2, 9·5 and 5 watts respectively. These, of course, continue the whole of the time the transformers are connected to circuit; further losses depend, of course, upon the out-of-balance load on the secondary or lamp circuits. The copper losses vary up to 12 watts, according to the state of the balance on the two legs, and are reduced to nothing when the load on the legs is evenly balanced. The open circuit losses can, of course, be reduced to a very great extent if a main switch is connected on the high voltage side of the transformer, so that when light is not required the transformer can be switched out of circuit.

The Foster Arc Lamp & Engineering Co., Ltd., have made a speciality of a compact form of auto-transformer for use with metallic filament lamps, which they have been able to put on the market at a very reasonable price, notwithstanding its high efficiency and excellent voltage regulation. The range of stock sizes is very extensive, and they are constructed for frequencies of 40, 50, 60, 75, and 83 cycles for secondary voltage of 25, 2 × 55, 45, 50, 60, 3 × 60, 65, 3 × 65, 100, 105, 110, and 165 volts, and for primary voltages of 240, 230, 220, 210, 205, 200, 110, 105, and 100 volts. We hope at an early date to be able to give fuller particulars of this apparatus.

A number of other firms have already completed or are engaged upon the design of special apparatus of this nature, and we hope at a future time to be able to give particulars of the more interesting of the new pieces of apparatus.

THE NEW EAST HAM TELEPHONE EXCHANGE

By J. W. O. Sandell

A CENTRAL battery telephone exchange equipment, of a type which is a novelty to London, was brought into use by the National Telephone Company last January at East Ham. The premises in which the plant is installed have been specially built for the purposes of a telephone exchange, and consist of a ground and first floor each having an area of approximately 1,870 square feet. The switchboard and its attendant apparatus, together with the operators' quarters, are accommodated on the first floor, the ground floor at present being divided up into offices and stores which are in use by the company, and two lock-up shops.

The main distributing frame, upon the vertical side of which the underground cables are terminated, is of the same standard design as that described in ELECTRICAL ENGINEERING of October 31st last in connection with the new Gerrard telephone exchange. It has a capacity for 1,760 outside lines, and is at present equipped with arresters for 1,050 lines. From the terminal strips on the horizontal side, 42-wire asbestos-

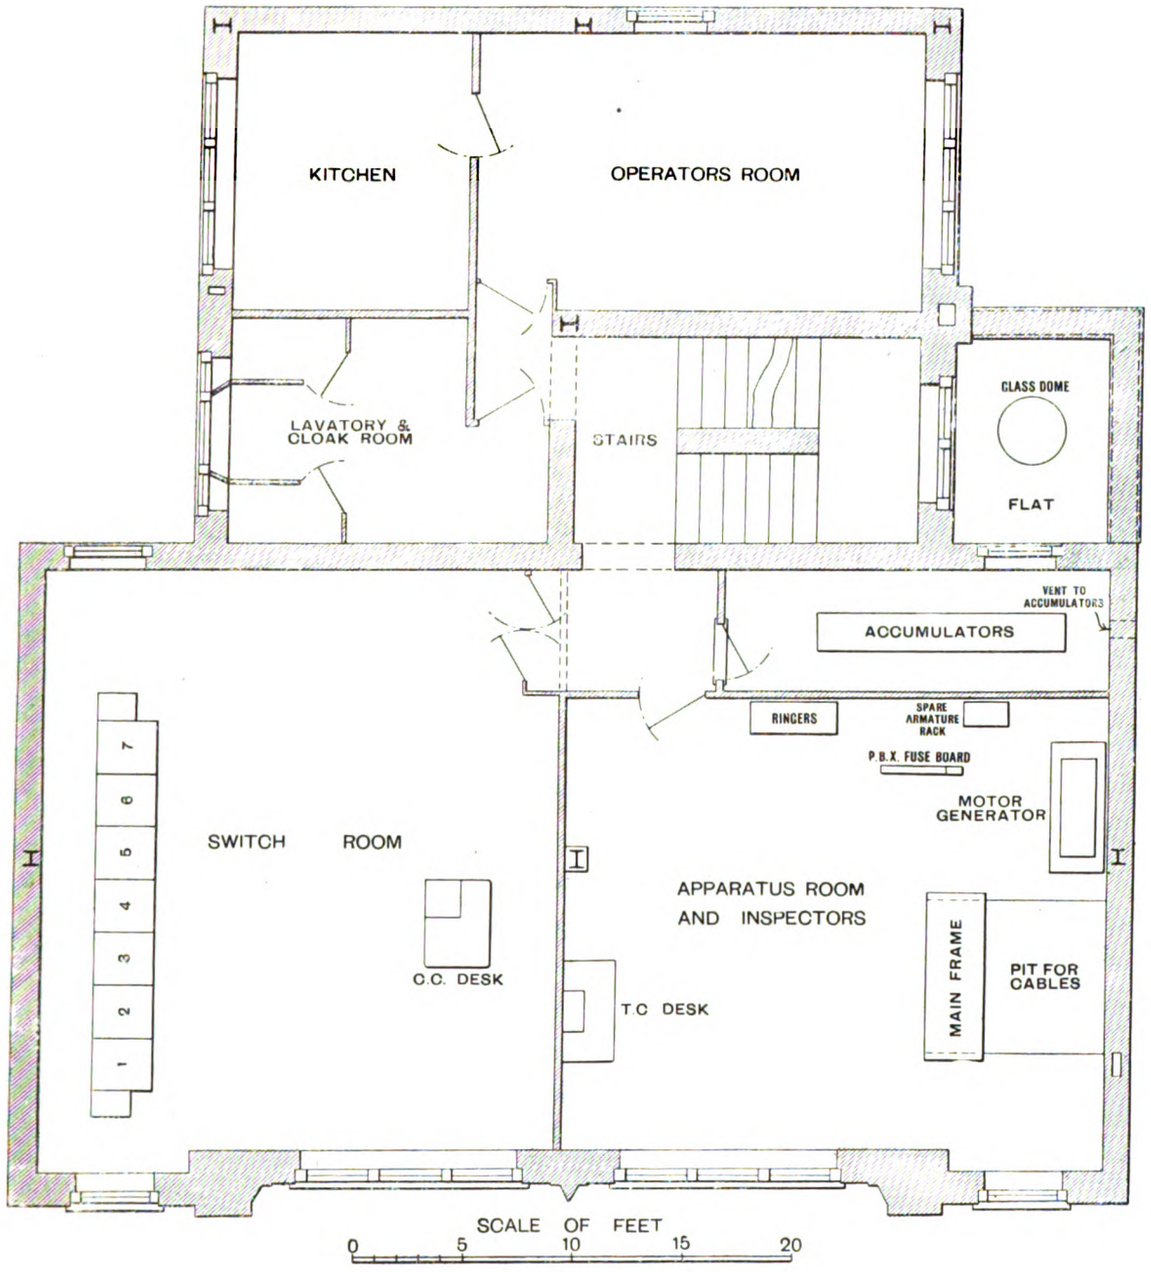

FIG. 1.—PLAN OF EXCHANGE, SHOWING LAY-OUT OF APPARATUS.

covered cable is carried to the switchboard, and there connected to the first jack of a series multiple, which is repeated every fourth panel through the switchboard.

Each section has accommodation for 400 subscribers' multiple jacks, and 80 outgoing junction multiple jacks in strips of 20 each, and the switchboard is designed for an ultimate capacity of 800 subscribers' lines and 160 outgoing junctions. It may here be noted that the

Digitized by Google

answering jack, in the ordinary acceptation of the term, has been abolished, the multiple jack serving a dual

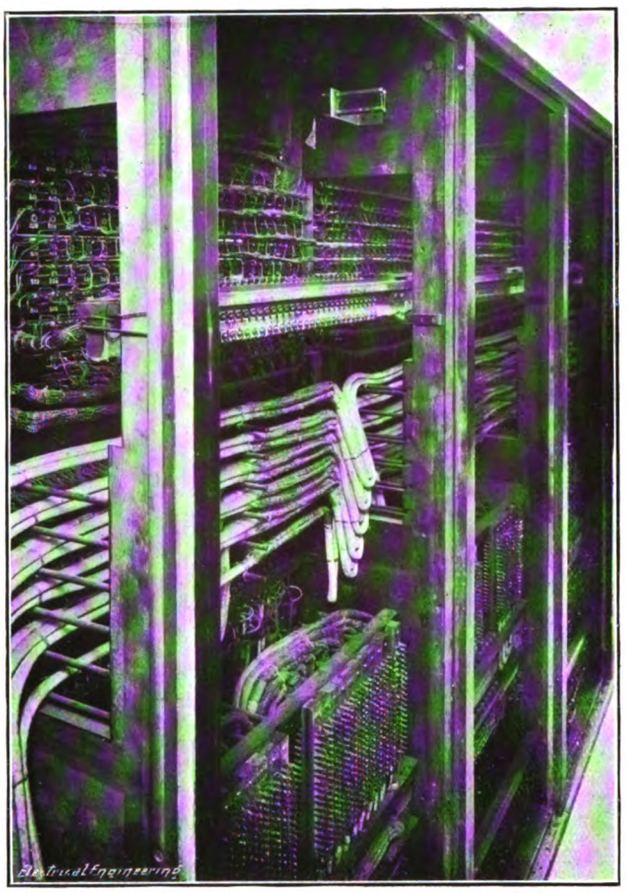

Fig. 2.—Rear View of Switchboard with Panels Removed.

purpose. To the inner springs and bush of the last strip of jacks in the multiple is connected a 63-wire cable of sufficient length to reach the next multiple jack when the switchboard is extended.

This cable is terminated on a strip of connecting terminals fitted in the rear of the last section, as shown in Fig. 2. At this point the tip or "A" lines are commoned together and connected to the positive side of the battery, and the ring or "B" lines are carried in 21-wire cable to terminals at the rear of the particular section in which the signals with corresponding numbers to the jacks are situated. Between these terminal strips and the connectors at the bottom of the section to which one end of the winding of the subscribers' calling signal is wired there exists a cross-connecting field, where, by means of single jumper wire—or, as is the case at East Ham, by wires made up in cable—the calling signal is connected to the "B" line inner spring of the jack.

The calling signal is of an automatic mechanical type, consisting of an electromagnet and a pendulous armature, to which is attached a spherical-shaped piece of aluminium, the latter being brought into view with the energising of the electromagnet is restored by gravitation when the electromagnet is de-energised.

The operation of the line circuit, shown in Fig. 3, will be readily grasped. When the circuit is completed by the removal of the subscribers' receiver from the switchhook, current flows from the positive pole of the battery through the "A" line jack contacts, the primary winding of the induction coil and transmitter of the instrument returning through the "B" line jack contacts and 300-ohm calling signal to the negative pole of the battery. The armature of the signal is thereby attracted, closing a local circuit which lights a pilot lamp common to a section. With the insertion of the answering plug into the jack, the calling signal is disconnected from the line, and restores mechanically as previously described.

The subscribers' operators' cord circuit is shown in Fig. 4. It will be seen that this circuit is divided by condensers instead of the repeating coil, which is usual with the regular central battery cord circuit used in larger exchanges; and, further, that a 16-cell battery is used in place of 11 cells, the purpose of this being to keep the transmission efficiency standard. The impedance coils, through which current is supplied for transmission, serve also as supervisory signals, and are of a similar type to the subscribers' calling signal, and the 500-ohm retardation coil connected to the sleeve conductors of the plugs provides the current for the engaged test. Provision has been made in the equipment of five ringing keys per cord circuit, for calling party-line subscribers by the selective system of pulsating ringing currents.

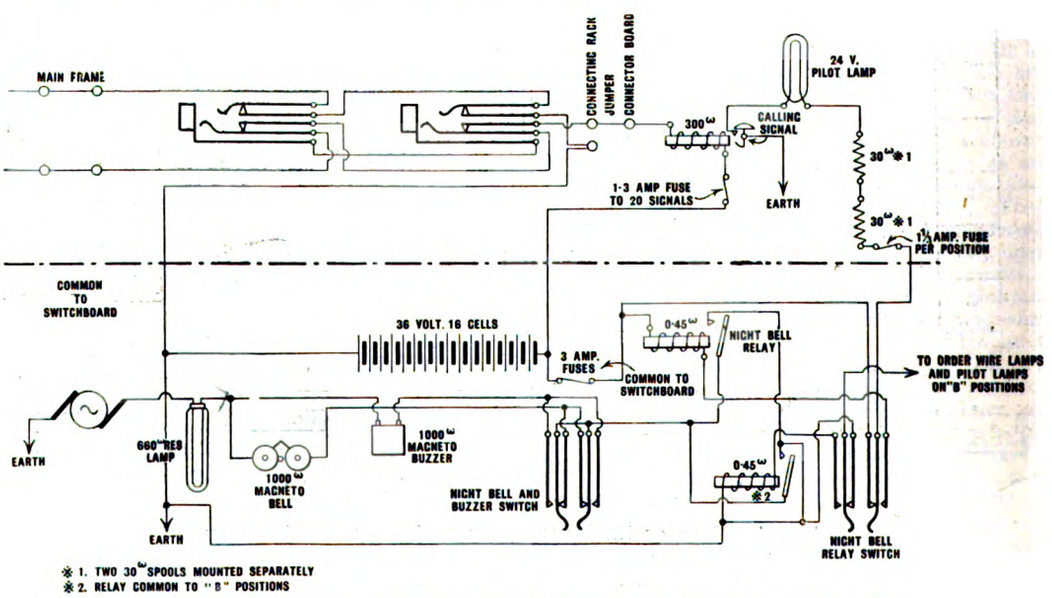

Fig. 3.—Diagram of Subscribers' Line and Night Alarm Circuits.

Fig. 5 shows a general view of the switchboard, the first three sections of which are junction positions, one of these is being used temporarily as an electrophone position, and the remaining four are subscribers' positions.

Digitized by Google

Each section constitutes one operator's position, and the principal dimensions are:—Length, 2 ft. 5 in.; width (including keyboard), 2 ft. 9 in.; height overall, 6 ft. 3 in. The "B" positions have each a capacity for 27 incoming junctions, and are at present equipped with 25. The connections of the junctions are practically the same as the standard circuits, the chief point of difference being that the cut-off relay, which is usually fitted in connection with the sleeve conductor of the plug, is in this case operated either by a key or plug-socket switch. The "A" positions have each a capacity for 200 subscribers' calling signals, which are mounted above the multiple jacks in strips of twenty; the present equipment is 500 signals divided between four positions. The keyboard and plug-shelf have capacity for 15 cord circuits, the full number being equipped; and the supervisory signals in connection with the cords are mounted immediately below the bottom strip of calling signals, in two strips of 15 each.

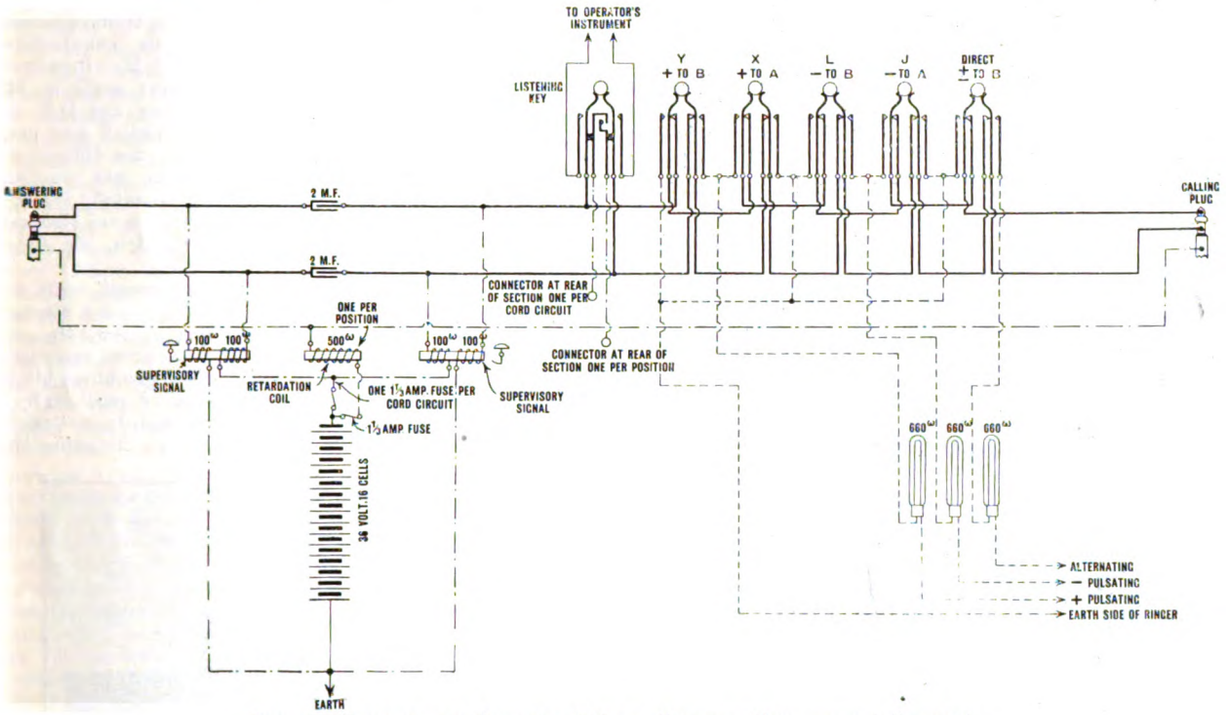

FIG. 4.—DIAGRAM OF OPERATORS' CORD CIRCUIT (SUBSCRIBERS' SECTION).

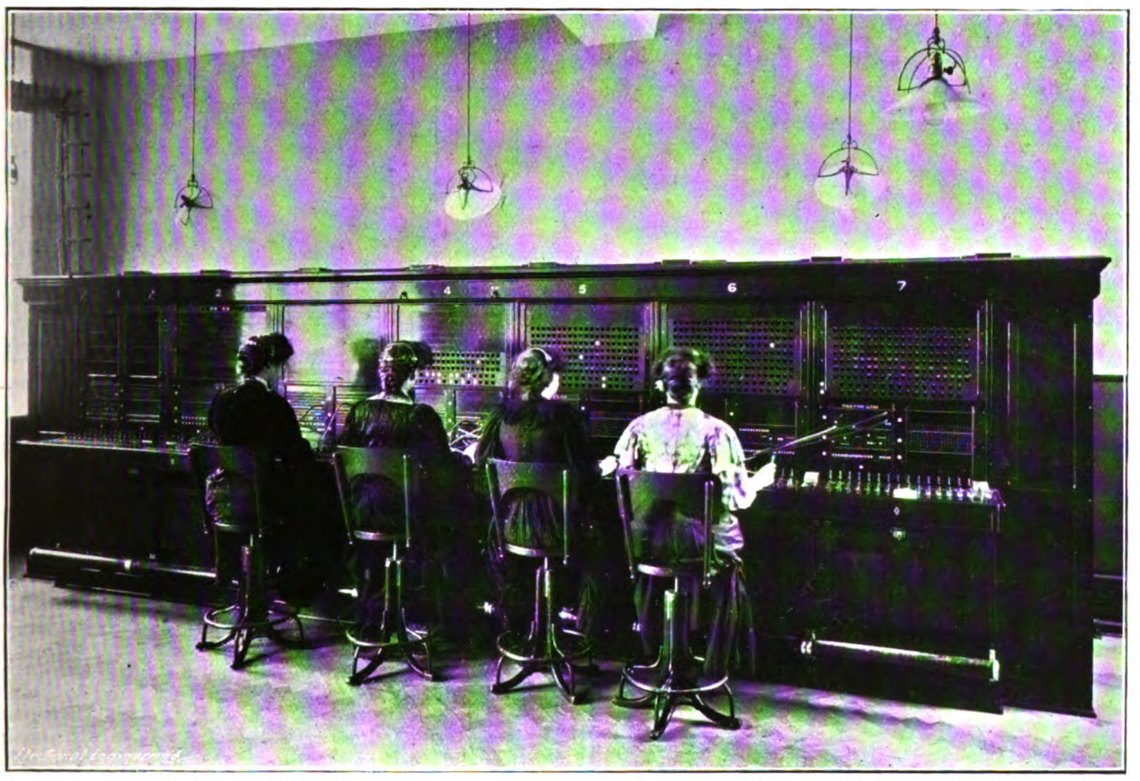

FIG. 5.—GENERAL VIEW OF SWITCHBOARD.

Fig. 6 shows the test clerk's panel. This embodies

Digitized by Google

all the principal features of the familiar test clerks' desk of larger central battery exchange equipments, but at the same time takes up less space. All the apparatus in connection with the testing circuits is contained in the panel with the exception of the battery of primary cells and condensers, which are accommodated in a teak case underneath.

A set of 16 Chloride cells in lead tanks supplies the switchboard with current for transmission and signalling purposes. The present capacity of the battery is 420 ampere-hours at a 9-hour discharge rate, but the tanks are large enough to allow of the plates being increased

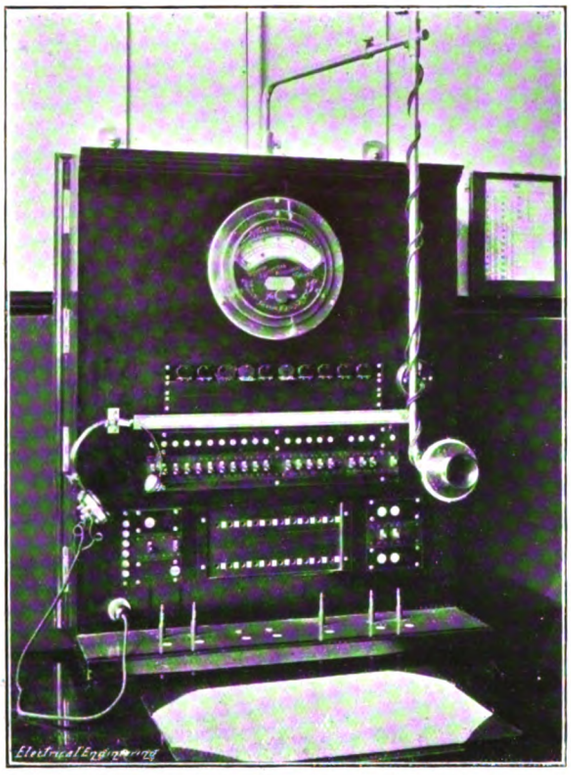

Fig. 6.—Front View of Test Clerk's Panel.

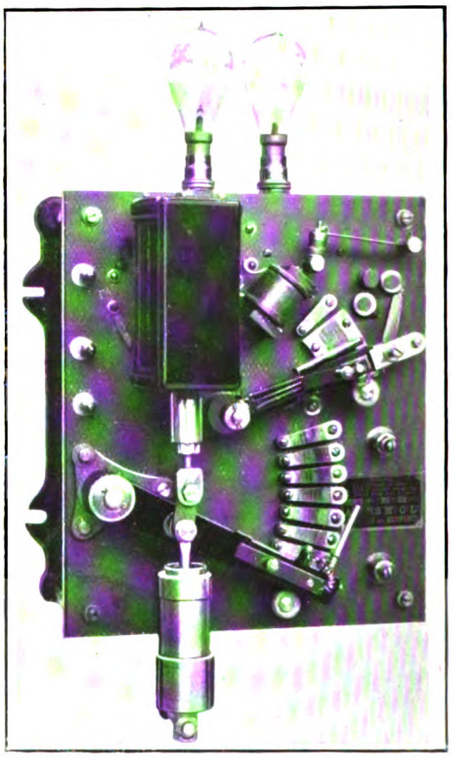
when necessary to give 720 ampere-hours at the 9-hour rate.

The charging set consists of a direct-coupled motor-generator, the output of the generator of which is 90 amperes at 45 volts. In addition, two ringing machines have been put in, which supply the alternating, negative, and positive pulsating currents required for ringing subscribers' bells, and also the busy-back and tone-test signals. One of these machines is a direct-coupled motor-generator, and the other a dynamotor which is supplied with current through a choke coil from the battery.

The number of subscribers' and junction lines with which the exchange was opened was 208 and 41 respectively, these figures including 178 lines transferred from the Barking exchange, which is now closed.

The building has been designed so that an additional floor can be added for installing a standard central battery equipment when the ultimate capacity of the present switchboard is reached.



Electrical Imports into Switzerland.—According to a consular report, the total imports of electrical apparatus into Switzerland during 1906, amounted in value to £148,400, as against £147,700 in 1905. Of these £1,700 and £1,900 were imported from the United Kingdom, showing a slight decrease. The average decrease of imports from the United Kingdom during the five years, has been 1·5 per cent. Germany is the principal country from which electrical apparatus is imported into Switzerland, and during 1906 no less than £113,000 of the total of £148,400 came from Germany.

A NEW PRINTING PRESS CONTROLLER

THE accompanying illustration shows an automatic starting switch specially designed for use in connection with printing machines, which has been patented by Mr. Frank Broadbent, and has been put on the market by the Adams Manufacturing Co., of Bedford, who hold a sole licence for its manufacture and sale. This new switch is not the first that Mr. Broadbent has invented for controlling printing machines; early in 1899 he took out a patent for an interlocked starter and D.P. switch, which he had designed in 1898, and the switch now produced has really grown out of the earlier switch, the difference being that while the switch patented in 1899 was mechanically operated, the new switch is electrically operated, and by this means quite a number of important advantages are claimed.

In explanation of the evolution of this switch, Mr. Broadbent says :—

"Some ten years or so ago it was impressed upon me that for special work, such as the control (that is, the starting and 'inching') of such machines as printing presses, the ordinary starter was a very poor device. Printing-press operators had for years been accustomed to 'inch' their machines bit by bit in order to bring the 'forme' to the required position by means of the ordinary striking gear. They simply see-sawed the striking handle backwards and forwards, so throwing the belt

Controller for Printing Press Motor (Adams Manufacturing Co.)

from the fast to the loose pulley, and *vice versa*. This enabled them to move the machine very slowly, or, as they called it, to 'inch' it along. When printing presses were electrically driven by individual motors the starting switch got precisely the same treatment as the ordinary belt-striking device, which means that the motor got several times its normal working current suddenly thrown upon it, and this current was repeatedly broken across the starting-switch contacts. The wear and tear on the switches was terrible; the overloads thrown on the motor were most destructive to the commutator and brush gear, to say nothing of the mechanical strains thrown upon the armature shaft and driving pinion. We endeavoured to induce machine operators to 'inch' with a D.P. switch whilst holding the starter on the first or second button of the starting switch. They did this, as long as we stood by and watched them, but no longer."

Early in 1899 Mr. Broadbent took out a patent for an interlocked starter and D.P. switch. The essential principle of this was that the starting handle, in being pushed over, carried with it the D.P. or circuit closing switch, and, when at the end of the travel, this switch was closed, all resistance was in circuit, and the starting handle automatically returned without any assistance from the operator and so started up the motor

Digitized by Google

gradually. By this means it was impossible for the operator to put the D.P. switch in unless all resistance was in circuit, and it was impossible also for him to "inch" or to break the circuit on the starting contacts. A disadvantage of this switch was the room it took up on the press, and to alleviate this an arrangement of solenoid control was introduced into the switch, by means of which it can be placed at a convenient distance from the machine, and operated by press buttons or a small "inching" switch placed near the operator's hand. We understand that the troubles and breakdowns due to ordinary methods of starting, including both the rheostat type of starter and also the drum controller, had reached such a pitch in 1904 that the Operative Printers' Assistants' Society made a claim for extra wages for those of their members who had to operate this class of apparatus. The reason for this may not be quite obvious, but it was a result of the large number of discharges that had taken place owing to the breakdowns of motors and starting gear. There was nothing now, of course, in the principle of solenoid control, but hitherto it had been usual and necessary to use two solenoids, one to operate the main switch, which in turn closed the circuit of a solenoid actuating the rheostat proper. The method of operation was to use a small switch to energise the main solenoid. As soon as the solenoid circuit was closed by this switch, the solenoid pulled up the main switch, thus closing the motor circuit and energising the rheostat solenoid, which then commenced to pull the rheostat starting lever slowly upwards against the retarding action of a dashpot or some equivalent device. This permitted of the starting gear being placed at a distance from the machine and operated by means of a small switch near the operator's hand, and by opening and closing the switch rapidly the machine could be "inched" and controlled with precision. There are, however, several disadvantages appertaining to this arrangement, first, on the score of initial cost, and also on the cost of erecting and connecting up the two separate pieces of apparatus. Further, electrical interlocking devices are required to make it impossible for the main switch to be energised unless the rheostat is at its bottom position with all the starting resistance in circuit. This means the introduction of a resistance (either composed of lamps or resistance units) into the solenoid circuit as soon as the starting lever commenced to travel. A fault or break in this circuit causes pumping, and renders the switch practically inoperative. Again, in order to economise in the consumption of energy by the rheostat solenoid, it is necessary to introduce resistance into its circuit, when in the normal full running position. Without these resistances the solenoids would have to be so liberally rated, to prevent overheating, as to make the solenoid system impracticable. Another disadvantage of the system is the difficulty of using a self-setting overload device, and it is only possible to protect the motor from overload by using either a circuit breaker which must be set by hand, or a safety fuse which has the same and other disadvantages.

The new switch has been designed with a view to obviating these disadvantages, and it may be pointed out that if the proposed Home Office Regulations come into force this year, the present method of solenoid control, that is, by means of a tumbler switch, will not be approved, and any accident arising therefrom, such for instance as the starting up of a machine on the restoring of a supply current after a failure, may, in the event of a fatal accident, place the switch manufacturer and contractor in a very serious position. The construction of the switch is simple and robust, and, as there is only one solenoid, no waste of energy takes place when the motor is running. The switch may be automatically released in the event of a break in the shunt field by connecting the holding on coil in that circuit. It will then pause automatically on the first resistance contact until the shunt field is built up, so preventing a rush of current. The cost, both initially and of erection, is reduced, due to the use of one apparatus instead of two. Electrical interlocking devices are eliminated as the switch is mechanically operated. There is thus a saving in the space occupied by the switch gear. As will be seen, the simple design permits of a very simple interlock between the rheostat and the shunt regulating rheostat. The motor can always start on its strong field, the shunt resistance being gradually introduced whilst the motor is accelerating, without the use of any additional solenoid. A self-setting overload release can thus be used, and cooling resistances are eliminated. The more certain action due to the cleaning of the contacts on the upward travel of the switch arm before the dashpot comes into play on the downward travel. There is a reduction in the amount of attention necessary, and there is the further advantage that it is impossible for it to start without the pilot switch being properly closed.

THE GRIEVANCE AGAINST THE NATIONAL PHYSICAL LABORATORY

The Committee's Report

FOR some two or three years a feeling has existed among professional men connected with the engineering and chemical industries, that the National Physical Laboratory was trespassing on the ground of private institutions and individuals, in conducting tests and investigations for ordinary commercial purposes. Public attention was directed to the matter in the Press, and, largely as a result of the energetic action of the Institute of Chemistry, the Treasury, on December 31st, 1906, appointed Mr. Gerald Balfour, Sir Andrew Noble, Bart., K.C.B., F.R.S., Sir John Wolfe Barry, K.C.B., F.R.S., Mr. W. J. Crossley, M.P., and Mr. R. Chalmers, C.B., as a Committee to inquire generally as to the work performed at the Laboratory. The Committee was instructed to give special attention to the following points:—

(i.) The character of the mechanical, physical, and chemical tests undertaken there;

(ii.) The possibility of their interfering unduly with the business of other agencies;

(iii.) The desirability of publishing the results of all such testing work;

and to report:—

(1) Whether having regard to the industrial interests of the country generally and to those of private agencies, any change is desirable in the scope of the work of the Laboratory; and

(2) On what lines any further development of its business should proceed.

The Committee sat for nine days, between March 18th and June 28th, to hear evidence from the following witnesses:—

Dr. R. T. Glazebrook, F.R.S. (Director of the National Physical Laboratory), Sir William Ramsay, K.C.B., F.R.S. (Vice-President of the Institute of Chemistry), Dr. Percy F. Frankland, F.R.S. (President of the Institute of Chemistry), Mr. Bertram Blount, F.I.C., Mr. David Howard (Past President of the Institute of Chemistry), Mr. E. W. Monkhouse (Burstall and Monkhouse), Mr. W. G. Kirkaldy, Mr. J. E. Stead, F.R.S. (Metallurgical Chemist), Mr. R. B. Haldane, K.C., M.P., Mr. C. J. Bagley (nominated by the Iron and Steel Institute), Mr. T. Nash (nominated by the Iron and Steel Institute), Mr. R. E. Spencer (nominated by Sir W. G. Armstrong, Whitworth & Co.), Mr. H. E. Harrison (Principal of the Electrical Standardising, Testing, and Training Institution, Faraday House), Sir Joseph Swan, F.R.S., Sir Arthur Rucker, F.R.S., Sir Alexander Kennedy, F.R.S. (President of the Institution of Civil Engineers), Sir William Preece, K.C.B., F.R.S., Mr. Alexander Siemens, Mr. R. Kaye Gray, Mr. W. H. Maw, Lord Rayleigh (President of the Executive Committee of the National Physical Laboratory), Mr. H. F. Donaldson (Chief Superintendent of the Ordnance Factories at Woolwich), and Mr. D. B. Butler (Owner of a Cement-testing Works).

The Committee's report, dated December 16th, 1907, was issued last week.

After reviewing the events which led to the foundation of the Laboratory and its opening in 1902, the report states that all the witnesses were unanimous as to the great value to the commercial community of the research work conducted there, and as to the high efficiency with which it is carried out. Particular reference in this connection is made to the investigations into electrical and engineering questions undertaken in connection with the Engineering Standards Committee, including those relating to the standardisation of electric glow-lamps.

There is ample evidence, the Committee says, that

Digitized by Google

work of this kind supplies a long-felt want in this country, and is already widely appreciated by manufacturers and "scientists"; and it has no doubt that the importance of the Laboratory will meet with a steadily increasing recognition. Various investigations have already been conducted on behalf of manufacturers yielding results of general scientific interest, such, for example, as a comparison of the properties of gutta percha and balata, undertaken for the India Rubber Company of Silvertown (made to confirm work done in the company's own laboratory).

The Committee is of opinion that any grievance which private agencies may urge against the Laboratory is, so far, "more theoretical than practical," for the number of cases in which routine or commercial testing of materials has hitherto been undertaken by the Laboratory has been exceedingly small, and the fees earned by this means are of "inappreciable amount." This has, however, rather been due to the want of adequate equipment than to any desire on the part of the Laboratory to abstain from competition with private enterprise; for, in the official statement issued by the Laboratory, and in the pamphlets giving lists of tests undertaken and scales of fees, no suggestion was made that any restriction as to the scope of the work was required in the interests of private agencies until 1906, when, as a result of the protests of the Institute of Chemistry, an exception was made in connection with chemical analyses. Incidentally, the argument that commercial work is financially necessary to the Laboratory is dismissed.

While looking upon the apprehensions of those interested in testing work as exaggerated, the Committee does not regard them as unreasonable or entirely without foundation, and considers that "a more precise formulation of the testing work proper to be undertaken by the Laboratory is evidently desirable in order that public and private interests may be, as far as possible, harmonised. To this end the Committee recommends that, subject to certain exceptions, the Laboratory should be debarred from undertaking "Contractual Testing," but should be free with regard to "Investigatory Testing." Contractual Testing is defined as "the ordinary testing of materials to ascertain whether their quality and behaviour are in accordance with the requirement of contracts. . . . It is usually strictly routine work within defined lines to determine whether samples accord with specification, and does not call for anything but care and observation." Investigatory Testing "is in the nature of investigation for commercial purposes of various substances in which no question of contract arises."

The following exceptions to this general rule are made:—

(1) There are some tests, chiefly electrical, thermal, optical, and other physical tests, which cannot be carried out adequately, if at all, in any existing private establishment. In such cases it would obviously be absurd to debar the Laboratory from undertaking the work merely on the ground that the tests are intended to ascertain whether certain materials comply with the requirements of a contract.

(2) No restriction should apply to "reference" testing wherever, in cases of dispute, the parties concerned agree to refer their differences to the authoritative decision of the Laboratory, or where the Laboratory is called in by a Court of Law or of Arbitration.

(3) In view of the character of the Laboratory as a public institution, it ought to be free to accept any work which any Government Department may desire to commit to it. In this category is included the work until lately carried out at Cooper's Hill on behalf of the Indian Government.

(4) The restrictions which should be observed by the Laboratory in connection with the testing of materials are not intended to apply to the testing and verification of instruments (and, in connection therewith, of their component parts), which is much more generally, and quite rightly, admitted to be within its proper functions. There are, however, some cases in which it is difficult to draw a clear line between instruments and materials. One important case of this kind which has been brought to the Committee's notice is that of glow lamps. Where such a doubt exists, it must be left to the executive committee of the Laboratory to decide what course of action should be followed.

As an additional safeguard against injurious competition with private enterprise, the Committee thinks that, wherever the same tests of materials are carried out by the Laboratory and outside agencies, care should be taken that the fees charged by the former should be at least as high as those normally current; in the case of reference testing they should be distinctly higher. While the Committee fully accepts the assurances of the Laboratory authorities that it was not their intention in any case to undercut prices, it thinks that more attention should be paid to this matter than appears to have been done heretofore.

On the question of the publication of all testing work conducted at the Laboratory, the Committee proposes to give the Laboratory more latitude. The existing rule is to publish all the results of investigations undertaken at the request of private individuals and fully paid for by them, except in special cases approved beforehand by the Executive Committee. In practice very few, if any, exceptions have been admitted. The Committee thinks that the rule, as interpreted, has proved too rigid and should be relaxed:

There is cogent evidence that insistence on immediate publication of results has already deterred, and must often deter, manufacturers and others from submitting to the Laboratory investigations likely to yield new results of great importance that would hardly be attainable through any other agencies. In one case it has been suggested that the operation of the rule has been to hand over to Germany an important branch of industry which might otherwise have been secured for this country.

This case, relating as it does to research in connection with metallic filament lamps, is interesting, and we therefore quote from the evidence given by Dr. Glazebrook in this connection:—

Another case in which difficulties have arisen is that which was mentioned by Sir Joseph Swan in his evidence. I should like, if I may, to read two or three sentences from Sir Joseph Swan's letter: "The question has occurred to me whether the Committee of the National Physical Laboratory would be agreeable to enter into any arrangement with me with the object of ascertaining the properties, electrical and general, of certain substances, more or less nearly related to the materials which have been examined in Dr. Harker's recent researches on high temperature furnaces. The substances I refer to are, generally speaking, the metals or metaloids of the more infusible earths, of which thorium, titanium, and tungsten would be types, and it might be desirable to extend the research so as to find the electrical properties of some of their compounds, particularly the carbides and oxides, in a compact and filamentary form." That was an enquiry into the materials which are now being used for the newest forms of incandescent lamps. As a matter of fact, the inquiry into the properties of some of these metals has since* been taken up in Germany, and lamps which are likely to supplant in great measure the carbon filament lamp are being made in Germany, and imported from Germany in large quantities. It is quite probable that, had we been able to take the research at that date, the German work on these lamps would have been done here, and the advantages that have accrued from the introduction of the lamps would have belonged to us rather than to Germany. It was Sir Joseph Swan's intention at first that the tests should be carried out with assistance from a company and worked for a company with which he is connected, and the negotiations occupied some little time. Finally he decided to take it up himself and to assist the Laboratory with his experience in the matter. By that time, however, this question of publication had been raised in a somewhat acute form. It appeared probable that this Committee was to be appointed, and the Laboratory Committee decided that while so important a matter was under the consideration of this Committee it was not desirable for them to undertake the work, with the result that the work has not been undertaken, and some of the results I have no doubt we should have arrived at have been obtained in Germany.

The Committee is of opinion that the Executive Committee of the Laboratory should hold itself somewhat freer than heretofore to exercise a discretion as to the withholding of results from publication, either wholly or in part, for a limited number of years. But they also

* From this it would appear that the correspondence in question took place some time ago, as the "Osram" lamp with its tungsten filament appeared on the market in 1905, and naturally must have been preceded by a long course of experimental work. In the interest of historical accuracy we beg Dr. Glazebrook to give us the date of this correspondence.—Ed. *E. E.*

Digitized by Google

think that in cases where publication is thus deferred a considerably higher fee should be charged to the persons for whose immediate benefit the investigation is to be carried out.

It was also suggested that the authorities of the Laboratory might with advantage be kept more closely in touch with the practical needs of industry by the institution of small Advisory Committees representative of different technical interests. The Executive Committee has already power to appoint sub-Committees of this kind, including members not already on the General Board or Executive Committee, although no regular meetings are held; and it is now recommended that these Committees be kept up-to-date and in close touch with the Executive Committee.

Sir Andrew Noble and Sir John Wolfe Barry, who are themselves members of the Executive Committee of the Laboratory, differ from the above report with regard to the restriction on "Contractual Testing," and recommend that a restrictive period of ten years would safeguard the interests of the public, which, they believe, would be best served by leaving the authorities entrusted with the administration of the National Physical Laboratory completely free (as is the case in the National Laboratories of Germany) to exercise their discretion in accepting or refusing any description of testing work.

This view of the minority has, however, not been accepted by the Treasury, who, in a Treasury Minute dated February 1st, 1908, approve of the recommendations made by the majority of the Committee. A note is appended to the Treasury Minute to the effect that the President and Council of the Royal Society accept in principle the recommendations contained in the report of the Committee, and the Executive Committee of the National Physical Laboratory have expressed their readiness to use their best endeavours to carry the recommendations into effect.

In addition to the quotations we have already made, several other interesting matters of a miscellaneous nature were referred to in the evidence.

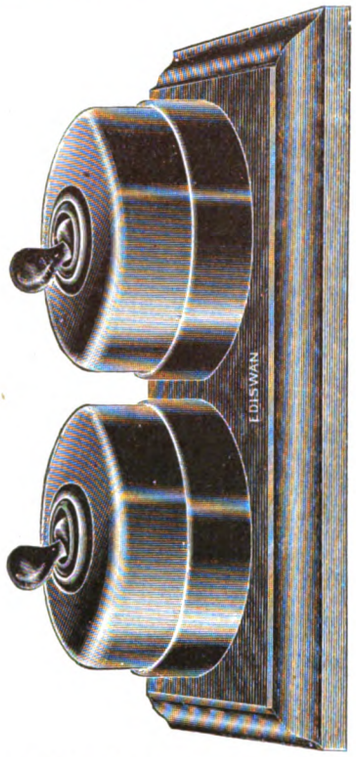
Dr. Glazebrook, speaking in reference to the necessity of the performance of some routine commercial test work to maintain a connection with actual engineering practice, said: "For instance, just lately we have been asked to investigate for the Board of Trade the material of a steam drum that burst in the south-west of London, and we have one or two other tests of that kind on hand. Of course we can carry out the actual measurements, but the measurements, if made by men who have no real experience of the behaviour of the ordinary materials of construction, lose a very great deal of their value." This presumably refers to the thermal storage drum that exploded at Greenwich, upon which the Board of Trade has recently issued its report.

Regarding the fees charged for testing instruments, Dr. Glazebrook said that if the Laboratory charged high fees this work would go to Germany, and, in fact, this was the case to a certain extent already.

Sir William Ramsay, in the course of his evidence, expressed the opinion that the analysts at the National Physical Laboratory were not sufficiently experienced to carry out some of the commercial tests submitted to them, and instanced two cases in which their results had been at fault.

Dr. Frankland particularly attacked the "Test Pamphlet" issued by the Laboratory to the general public, containing lists of tests carried out and scales of fees. Private practitioners, he said, "have now to meet the competition of a State-aided, non-rate-paying concern, which advertises for work in a manner which would universally be regarded as derogatory to the dignity of a professional man, and which charges low fees, and issues certificates bearing the seal and imprimatur of a national institution. No professional man would ever think of sending out a document of this kind. Amongst all professional men, every form of advertisement is regarded as in the highest degree derogatory. . . It is entirely contrary to professional etiquette to issue a list of charges to the general public." He also compared the Laboratory's fees in some instances with those charged by private practitioners: Determination of calorific value of coal, fee, 15s., for a single sample; the usual professional fee for this would be £1 1s. Determination of percentage of ash in arc lamp carbons, per carbon, 10s. 6d.; the usual fee is £1 1s. The National Physical Laboratory authorities propose to charge two guineas for chemical tests of steel rails, or about half the fees formerly and usually charged. Probably if the National Physical Laboratory charges only two guineas for a steel rail it will be impossible for a private practitioner to get more, although he has been getting more.

Mr. H. E. Harrison drew particular attention to the advantage which has been taken in some instances by private firms, who use the National Physical Laboratory certificate for purposes of advertisement. He read the following extract from the prospectus of the Premier Accumulator Co., Ltd.:—"The Premier Accumulators have recently been exhaustively tested by Dr. Glazebrook, the Director of the National Physical Laboratory (President of the Institution of Electrical Engineers). The tests, which were of the severest description, extended over four months. They thoroughly demonstrated the solidity of the special paste and the ability of the accumulators to withstand abnormal rates of charges and discharge and yet attain the average efficiency of 92·5 per cent., which is much larger than that obtained by any other accumulator. A reprint of the article in the *Electrical Review* of 1906, embodying Dr. Glazebrook's report, is enclosed herewith. The original report is in the possession of the Premier Accumulator Co., of Northampton, and can be inspected by anyone interested." That appeared in the original prospectus, and no doubt assisted very materially to float the company. Mr. Harrison also showed a copy of the firm's present price list with the report. Another document he produced related to a "Lamp Guarantee." "The British Thomson-Houston Co. offered to supply three standard 240-volt B.T.-H. Edison lamps of each c.p. for test by the National Physical Laboratory, provided a competitor who, it was understood, had agreed to this alternative guarantee of 775 hours at 3·9 watts per candle, would do likewise. This suggestion was accepted, and in due course the 18 sample lamps (nine selected by each maker) were received by the National Physical Laboratory and the test begun." The lamps were tested, Mr. Harrison continued, and although it says definitely in the report of the Committee that unless special permission is obtained not to have results published, they shall be published, yet they were not published. The lamps by the other maker, which are called A, did not come up to the requisite standard, and instead of these results being published they are kept secret. Owing to the fact that results are not always published, a maker does not hesitate to send his lamps up to Teddington as he would send them to Faraday House. When we hand over a report it becomes the property of our clients, but we say either it must be published in full or not at all. That is our usual condition. Teddington is in a very different position.



Sir William Preece, in the course of his evidence, said:—"Here is a place open to the whole country, and if anybody knows that any fad that occurs to him can be scientifically tested for a small sum by the National Physical Laboratory, he will go to the National Physical Laboratory and get it tested. You cannot go to private individuals; they charge too much. It is so difficult to get any private man who owns a laboratory to go thoroughly and earnestly into another man's fad, but with a national institution like the National Physical Laboratory, with such able assistants and such a capable director, whatever question is brought to them they seem to take in the same earnest way as if it had been their own suggestion. I think there is a very large field for the National Physical Laboratory for research in that direction. . . . In my own case I have sent to them three or four times new accumulators for secondary batteries, that have been brought to me, particularly for ignition purposes in motor-cars. When they come I invariably send them to the National Physical Laboratory and get them tested there. They are thoroughly well tested, and reports and certificates are always very complete, and the charges are very moderate. Those are things that you cannot give to private people. Sir William Preece also spoke at considerable length with regard to the testing of incandescent lamps. He thought it desirable that they should bear a mark which would be some guarantee of their conforming with the standards of the Engineering Standards Committee, and said that the Board of Trade, although they sympathised very much with the desirability, said that the only way of its being brought about would be for some testing authority to be legalised by licence to hold the mark. He suggested that the National Physical Laboratory should be this authority, and that Edinburgh, Dublin, Manchester, and Bristol might be made subsidiary to the National Physical Laboratory, so as to avoid undue concentration of work at Bushey.

New System of Wiring.—A description is given in a recent number of the *Elektrotechnischer Anzeiger* of a system of interior wiring in which protected insulated wires are used. The two insulated wires are surrounded by a rigid tube of copper, brass, or iron, which fits tight around the pair. This covering may be a seamless tube, in which case the material can be procured in lengths not longer than 22 ft. If the covering is rolled and folded, however, it can be obtained in lengths of 325 ft. if necessary. These tubes are very small in diameter, and as the metal covering is only 0·3 mm. thick, they are easily handled, and bent to the required shape. Special clamp joints and other fittings are provided, and it is practically impossible for moisture to get to the insulation. The tubes can be laid on the surface or in the plaster.

A NEW SWITCH

THE accompanying illustration shows a new form of switch which has been introduced by the Edison & Swan United Electric Light Co. for use in positions where a "Wedge" switch with the usual elevation could not be used. So short is the projection of this new type, which has been named the "Phlatta," that it can be fixed close to the moulding in places where doors open against a side wall, and where consequently the ordinary tumbler switch has to be placed some distance away in order that the door, in opening, may clear it. Its neat appearance also renders it suitable for use in positions

Specially Flat Form of Switch introduced by the Edison & Swan Electric Light Co.

where other types would look unsightly. The parts are made and assembled at the Ediswan Works, Ponder's End, Middlesex. The principle on which it works is identical with that of the well-known "Wedge" type, also made by the company, in which the contact-making parts are enclosed in a block of vitreous porcelain, thus rendering arcing impossible, and, in addition, securing an exceptionally high insulation resistance. The movements are carefully balanced, and owing to the high quality of the spring action a particularly quick make and break is effected. In action the switch is noiseless, and works much more smoothly than the ordinary type of "tumbler." A specially thin polished wood base, which may be round, square, or oblong, is made for this form of switch.

BULK SUPPLY TO THE MIDDLESBROUGH CORPORATION

IT will be common knowledge to many of our readers that when the Cleveland and Durham County Electric Power Company applied for parliamentary powers in 1900 many Corporations in Durham and Yorkshire opposed their application, among the opposers being included the Corporation of Middlesbrough. The opposition was unsuccessful, but the Corporation continued to extend their undertaking, and obtained some valuable consumers within the Borough. At the end of 1906, when the Cleveland Company became associated with new management and with Messrs. Merz and McLellan as its consulting engineers, an extremely progressive policy was adopted about that time. The Corporation of Middlesbrough were in the position of requiring more plant; unfortunately, their generating station had been erected upon a very poor site as regards foundations, and was, moreover, situated too far from some of the large works in the area to make it possible for its system of low tension continuous current supply to be extended to reach these works economically.

The Corporation, therefore, were face to face with the choice of two alternatives, the first being to lay down a new generating station, and, hampered with double capital upon the back of the undertaking, to endeavour to compete with the larger Power Company who had the right to supply within the Borough. The second was to take a bulk supply from the Power Company and act as authorised distributors. After due consideration they very wisely selected the latter alternative, and the value to them of this decision was accentuated by the fact that when the question of price was discussed the Company agreed to offer better terms if the Corporation were prepared to allow them to supply a portion of the district containing some of the large iron and steel works directly without passing through the Corporation as a distributor. This the Corporation agreed to, the Company in its turn agreeing that the Corporation should continue to supply the valuable district containing sundry shipyards and engineering works, in which it had already laid mains. One of the conditions of the agreement is that the Cleveland and Durham Electric Power Company will give the Middlesbrough Corporation supply in the form of continuous current, and at a sub-station provided by the Company in the heart of the works district reserved by the Corporation. As the Corporation generating station contains small plants and is not very commercially efficient, it is proposed to use this generating plant to a great extent as a peak load station, and to take most of the flat load current from the Company's sub-station. By this means the Corporation will purchase at an exceedingly low price, and their own high generating costs being only on peak load will not affect to a great extent the average cost of all units consumed.

The sub-station built for the bulk supply to the Corporation is situated at a point approximately four miles from the Grangetown power station and one mile from the Newport power station of the Power Company, and two one square inch mains for carrying three-phase current at 11,000 volts are laid into the sub-station. The whole of the high-tension switch gear is of the Electric Co.'s (A.E.G.) make, and the high-tension board consists of two feeder panels and two transformer panels, each of the brick-work type, and a bus-bar isolating switch, the feeder panels being equipped with "Merz Price" patent protective relays; the current transformer panels are also fitted with overload relays for the protection of the transformers.

In the sub-station are installed two rotary converter sets each of the capacity of 700 kilowatts, and comprising a three-phase static transformer for each machine, suitable starting and synchronising panels (the synchronising being done on the low tension side), and two six-phase rotary converters (whose synchronous speed is 480 revolutions per minute), fitted with a shunt wound mid-wire booster direct coupled. The rotary converter sets are of Westinghouse manufacture, as is also the low tension three-wire direct current switchboard. This board contains panels for four cables and two machines, and has two sets of bus-bars, to either of which any machine or feeder may be switched without the use of plugs.

A CHEAP FORM OF ELECTRIC KETTLE

THE most serious obstacle in the way of the introduction of electric heating and cooking appliances in small installations has been the expense of the apparatus. The cost of current in such appliances is not as serious as is often supposed, on

New Electric Kettle (Simplex Conduits, Ltd.)

account not only of the cheaper rates available in most districts for power and heating, but the very short time which efficiently constructed apparatus requires to be in use. In order to popularise the use of electric kettles by the small consumer, Simplex Conduits, Ltd., have introduced the type of kettle shown in the accompanying illustration, which is listed at the low figure of 10s. It is made of tin of pleasing design, and has a capacity of 1¾ pints. The consumption is 500 watts, and it will boil its full capacity of water in about 12 minutes.

ELECTROCHEMISTRY AND ELECTRO-METALLURGY

IN the *Elektrochemische Zeitschrift* of February, Josef Rieder describes "Impressions produced upon Photographic Plates by means of Electric Waves." The method adopted for retaining the impressions of electrical waves is the coherer, which is a tube filled with powdered metal, and which under the influence of electric impulses alters its resistance. The exact cause of this change of conductivity so produced is not quite clear. It is, however, supposed that the waves of electricity cause sparks to spring between the particles of metal powder; this causes partial fusion, and thus conducting bridges are produced. If this explanation is correct, Rieder thought that it should be possible to cause these impulses to become impressed upon a photographic plate. Accordingly, he drew a figure upon a glass plate with a solution of shellac; before allowing it to dry fine aluminium powder was sprinkled over it, and after drying it was placed, with its back against a very sensitive photographic plate, in a box, so that it was completely shut out from the light. He found after subjecting it to the action of electric waves produced by the sparking of an induction machine that on developing the plate a complete image of the drawing had been produced. In order to test whether aluminium powder itself would act upon a photographic plate without the influence of the electric impulses, another plate prepared in a similar manner was left in contact with a photographic plate, but no image was produced.

He found, also, that the thinner the layer of aluminium powder the greater the intensity of the action upon the plate. It was further found that the action was greatest when the back of the glass plate upon which the aluminium coated drawing had been sketched was backed with a sheet of metal. Further experiments were then made in the following manner. A rubber stamp was dipped into a solution of rosin and then pressed down carefully upon a clean sheet of glass. By this means a fairly clear impression was obtained. After drying the plate was gently warmed so as to soften the rosin, and then sprinkled over with aluminium powder, the excess of aluminium being dusted off when the rosin had hardened again. This plate so prepared was then placed with its back against a sheet of copper, and against this, in turn, a photographic plate was placed. The plates were then put into a light-tight box. In order to produce the electric impulses a small influence machine, capable of producing a 3 cm. spark, was used, a receiving rod 50 cm. high being employed on the box. The machine was placed in the author's dwelling, and the box and plates were removed 70 metres away from the house. After working the machine the plate was developed, when a complete photograph of the stamp was found to have been produced. Rieder thinks that an apparatus might be constructed to show the atmospheric conditions, the intensity of the photographic image depending upon the intensity of the waves. He suggests that a glass plate with only one spot of powder upon it should be fixed in a box, and a sensitised film should be passed before it by means of clock-work or other mechanical arrangement. By this means if there were electrical disturbances in the neighbourhood the film would show them, the intensity of the influences being shown by the intensity of the photographic image. It might also be used for taking the Morse code, the dot and dash being shown by the length of the mark upon the sensitised film, the powdered spot acting upon the plate during the period that it was subjected to the electrical impulses. If this principle can be satisfactorily worked out, it appears we have here a very valuable advance, or the possibilities of a very valuable advance, in wireless telegraphy.

In the *Elektrochemische Zeitschrift* of February there is also an account of the German Government plant for the electrolytic production of hydrogen for the purpose of inflating the army balloons. The oxygen which is at the same time produced is compressed into cylinders, and can be employed for a variety of purposes. Until recently the electrolytic methods of preparing hydrogen for filling balloons have not been able to compete with the purely chemical. The gas obtained by chemical methods, *e.g.*, by the action of sulphuric acid upon iron, is not so pure as that produced electrolytically, and has therefore less lifting power. The plant referred to has been erected by Messrs. Schuckert & Co., of Nuremberg (Electrizitäts-Aktiengesellschaft vormals Schuckert & Co.), and is made to deliver 600 cubic metres (21,190 cubic feet) of hydrogen in 24 hours. It is, however, capable of being worked to almost double this capacity. The power is obtained from a dynamo directly coupled with a 300 h.p. motor. The current delivered is 1,800 amps. at 85 to 110 volts. The compressing machinery is driven by a 70 h.p. motor. In order to provide against accidental explosions should the gases leak into the buildings, the dynamos and motors are all cased in, and the electric lamps are enclosed in air-tight globes. The electrolysing cells are divided up into three groups, which can be separately operated from the switchboard. Each group contains 34 cells connected up in series, and which require 600 amperes. In the Schuckert system no diaphragm is used to separate the anode from the cathode compartment. The electrolysing cells consist of iron tanks, and the anode and cathode are separated by means of bells, consequently the pressure of the gas must not be too great either at anode or cathode space, or the gases will mix and an explosive mixture be produced. The electrolyte is 20 per cent. potassium hydrate, and both anode and cathode are of iron. The maximum efficiency is said to be obtained when the electrolyte has a temperature of 60—70°. This temperature is reached when the plant has been in operation for about six hours. At this temperature 6·4 kilowatt hours are required to produce 1 cubic metre (35·16 cubic feet) of gas. To prevent the solution being cooled by external influences, the whole electrolysing tank is placed in a wooden box, the spaces between the iron walls and the wood being packed in with sand. The whole plant, with the exception of the copper current conductors and the insulating material, is made of iron. The renewals required are very slight. Once a year insulating material requires to be renewed, and every now and then fresh iron anodes are required. About 2 kilograms (4·41 lb.) of anode is consumed for every 100 cubic meters (3,530 cubic feet) of hydrogen produced. The gas is produced at a water pressure of 80 mm. (3·1 in.), and has a purity of 97-99 per cent. It is washed free from any alkali which may spray over it by first passing over a surface of water, and then up a tower containing coke, over which water trickles

TANTALUM LAMPS FOR ALTERNATING CURRENT

IN the earlier days of the tantalum lamp a good deal of unexpected trouble was experienced with the peculiar behaviour of the filaments when used on alternating currents, which made the life of the lamps when used on these circuits so uncertain that the makers were forced to recommend that their use be confined to continuous-current circuits. The effect produced by alternating currents was very peculiar, and consisted in a breaking up of the filament into short sections in a way quite absent in the case of continuous currents. The phenomenon was well illustrated in some micro-photographs of tantalum filaments which had been used on continuous and alternating circuits, under our own observation, which were shown at a meeting of the Institution of Electrical Engineers, and reproduced in Electrical Engineering, Vol. I., page 153. A satisfactory explanation of the effect has never been forthcoming, but we were pleased to be able to make the announcement last week that Messrs. Siemens Brothers Dynamo Works, Ltd., were now able to supply lamps of certain sizes, suitable for use on alternating as well as continuous-current circuits. Messrs. Drake and Gorham, who have always been to the fore regarding the sale of these lamps, have during the week issued a circular that sets forth the sizes now available. Looking through the list we find that all the lamps from 50 to 75 volts, which range in sizes from 12 to 32 c.p., are available for alternating currents, as are also the 100 to 130-volt 25-c.p. lamps, and the 32 and 50 c.p. lamps for 100 to 160 volts. The 16-c.p. lamp for 100 to 120 volts, of the same efficiency as those already mentioned, viz., 1·7 watts per British candle-power, is only recommended for continuous currents, but a 16-c.p. lamp of slightly lower efficiency (2·2 watts per c.p.), is available for alternating currents at these voltages. Another size which is at present only available for continuous current is that for 25 c.p. at 140 to 160 volts. It should be said that better results are, as a rule, obtained on 50 cycle circuits than on those of higher frequency.

Manchester Local Section of the Institution of Electrical Engineers.—The annual dinner, at which some 150 members were present, was held at the Midland Hotel, Manchester, on Friday last. Mr. M. B. Field in the chair. Among those present were the Mayor of Salford (Mr. I. Frankenburg), Dr. R. T. Glazebrook, Mr. Robert Hammond, Dr. C. Hopkinson, and Mr. S. Z. de Ferranti. The Lord Mayor of Manchester (Mr. Holt), in a letter of apology for his absence, said that he would have liked to have been able to give official recognition to the representatives of an industry by which the city had benefited so much. After the loyal toasts, Mr. Robert Hammond proposed the Corporations of Manchester and Salford, and in the course of his speech mentioned that the supply of electricity per head of population was larger in Manchester than in almost any town in the country. The Mayor of Salford responded for both Corporations. Mr. J. Adamson proposed "The Institution of Electrical Engineers," and stated that a technical library was urgently needed, as well as a suitable assembly room where the meetings of the many scientific societies in Manchester could be held. Dr. R. T. Glazebrook, in responding to the toast, mentioned that the Institution intended perpetuating the memory of Lord Kelvin, their late president, in some suitable way; and he had no doubt that the Manchester Local Section would be anxious to help. Dr. Glazebrook also spoke of the success of the London volunteer corps of electrical engineers. Other speakers were Mr. Ferranti, Mr. Miles Walker, and Prof. F. G. Baily (Chairman of the Glasgow Local Section).

ELECTRICAL SCIENCE

British and American

On the Contact E.M.F.'s between Mercury and Electrolytes.—A Paper on this subject was presented at last Friday's meeting of the Physical Society by S. W. J. Smith and H. Moss. It is well known that if the surface tension between mercury and an electrolyte be examined by the Lippmann capillary electrometer method, the surface tension in the case of practically all electrolytes rises to a maximum and falls as the E.M.F. applied to the electrometer increases. Paschen showed that in many cases this E.M.F. of maximum surface tension was equal to the natural contact potential difference between a dropping mercury electrode and a still mercury electrode immersed in the same mass of electrolyte. Since the dropping electrode is supposed to attain the same potential as the electrolyte, this observed E.M.F. is the measure of the contact E.M.F. of mercury and the electrolyte. Recently Palmaer has shown that he could reduce the observed potential difference between the still and dropping mercury until it became zero, and even changed sign, by the expedient of adding small portions of certain substances to the electrolyte. Solutions giving the zero E.M.F. between still and dropping electrodes are called "null" solutions, and were supposed by Palmaer to make absolutely no contact potential difference with still mercury, which implies that the zero potential difference between mercury and a null solution occurs at the point of maximum surface tension. The present authors now show in their Paper that this deduction of Palmaer's is not necessarily true, and that his results leave the knowledge of the contact potential difference between mercury and an electrolyte substantially in the same state of uncertainty as before. To show this the authors first investigated new ways of producing null solutions. One way consisted in adding sodium sulphide in very minute quantity to potassium chloride solution as electrolyte till the electrocapillary curve (between surface tension and applied E.M.F.) had its maximum at zero applied E.M.F.; and a second kind of null solution was obtained by using a different electrolyte and altering its concentration till the maximum of the electrocapillary curve was at zero E.M.F. In the Paper, the laws governing the effect of adding minute proportions of sodium sulphide to potassium chloride solution are fully worked out, and are shown to be remarkably affected by the presence of dissolved oxygen in the solution. But the point of principal interest is brought out by the measurements of one null solution against another; it is seen that the potential differences between different null solutions are not the same, after allowing for the small contact E.M.F. between electrolytes.

Continental

Specific Inductive Capacity and Dissolving Power.—That there is a certain parallelism between the dissolving power and the dissociating or ionising power of a solvent has been suspected for some time. And as the power of a solvent to split a solute into ions goes hand in hand with its dielectric constant, it is natural to expect a close connection between the dielectric constant and the dissolving power of a liquid. Such a relation has now been discovered by P. Walden, who gives the results of his researches in No. 5 of the *Zeitschrift für Physikalische Chemie*. According to Rothmund, the mutual solubility of liquids is proportional to their dielectric constants. The author, however, takes a "normal electrolyte" in the solid state, viz., tetra-ethyl ammonium iodide, $N(C_2H_5)_4I$, and dissolves it to saturation in a number of different liquids, comprising such various types as water, acetone, ethyl bromide, and benzonitrile. He compares the dissolving powers of these with their dielectric constants as determined by their refractive indices for long waves, and finds that the dielectric constant is proportional to the cube root of the dissolving power. This law resembles that found by Baur for the concentration of an electrolyte in two contiguous solvents.

Radium and Lithium.—In the *Comptes Rendus* for February 17th, Miss Gleditsch publishes the results of her search for lithium in radium minerals, a search the interest of which lies in the connection between radium and lithium discovered by Sir W. Ramsay. The authoress finds that all the radium minerals analysed do contain lithium, but in quantities too minute for chemical analysis. These quantities were therefore estimated spectroscopically, by preparing definite mixtures of lithium and sodium salts, and observing the prominence of their respective lines. Among the minerals investigated were pitchblende of Joachimsthal and Colorado, carnotite, Cornish chalcolite, autunite, and thorite. Of all these, carnotite contained the largest proportion of lithium (0·05 per cent.), and Cornish chalcolite the smallest (0·0001 per cent.). Autunite and thorite contain no copper, but a good deal of lithium. This might be attributed to the transformation of the copper into lithium, but then chalcolite contains 6·54 per cent. of copper, and very little lithium. The authoress finds no conclusive evidence against Ramsay's hypothesis, but also very little to corroborate it.

CATALOGUES AND PAMPHLETS RECEIVED

FOLDING STEPS.—We have received a new leaflet from Messrs. J. H. Heathman & Co., describing a form of folding lattice step-ladder, in which an ingenious arrangement of folding treads is adopted, whereby the thickness of the appliance when closed is reduced to 2¾, as against about 6 in. with the ordinary design. A form without supporting legs is made to close to 1½ in., and open to 6 in. width of tread.

INCANDESCENT LAMPS.—A neat coloured show-card is to hand from Cryselco, Ltd., calling attention to the carbon-filament lamps made at their works at Bedford.

MAGNETIC SEPARATORS.—Messrs. Plutte, Scheele & Co. send us a list of electro-magnetic separators of the "Geist" type, in which the magnet is stationary, and is surrounded by a revolving non-magnetic drum provided at intervals with thin iron projections on its periphery. The material to be treated is conveyed past the drum at a tangent and, as soon as it comes under the influence of the magnet, the iron particles are attracted, and are drawn off by the revolving drum until they are no longer under the influence of the magnet when they fall off by their own weight. The non-magnetic material is not attracted by the magnet, and consequently falls off at once.

MOTOR-CAR ACCESSORIES.—The newest catalogue from the General Electric Co. deals with motor-car accessories. A full series of ignition apparatus is included, comprising multiple and distributor coils, small coils for cycles, contact makers and distributors, sparking plugs, high and low-tension wires, connectors, switches, pocket ammeters and voltmeters, electric light fittings for omnibuses and private cars to take small Osram lamps, direction indicators, speaking tubes, accumulators for ignition and lighting, dry batteries, primary batteries, motor generators, and switchboards for accumulator charging, portable lamps, various tools, and Coates' patent high-tension magneto apparatus, which is manufactured at the company's Manchester works.

SMALL MOTORS AND GENERATORS.—Two new leaflets dealing with small machines have been issued by the Crypto Electrical Co. A series of small motor-generators is listed, ranging in output from 200 to 4,000 watts for converting from alternating to continuous current. A combined machine with a single frame for the same purpose is also included, which is specially intended for the charging of ignition accumulators in garages, &c. The output of this set is 6 to 7 amperes at 15 volts. Another leaflet deals with small induction motors for single, two- and three-phase circuits.

THE WORKING MEN'S COLLEGE, MELBOURNE.—The prospectus of this College for the year 1908 contains complete information concerning the various courses of instruction which can be taken there. The College, founded in 1883, by the Hon. F. Ormond, has been repeatedly enlarged by means of private, public, and government subscription, and now provides classes in all the conceivable branches of the handicrafts, arts, and sciences. The average number of students enrolled per term is over 2,000, the total number of students at present enrolled being 4,130.

WATTMETERS AND PHASEMETERS.—A new list from the Union Electric Co. contains particulars of a series of Hartmann & Braun moving coil wattmeters of switchboard type for continuous and alternating currents, with suitable resistances, &c., including special neutral point resistances for use on three-phase circuits, where the neutral point is not accessible, and a direct-reading phasemeter, which can be graduated in degrees or power factor. Full size reproductions of the scales are given, from which it is seen that they are particularly clear and easy to read

---

Applications of Electricity in Korea.—The American Consul-General at Seoul, reporting upon Korea as a market for electrical appliances, fans, and motors, says that the Koreans are rapidly installing small motors in their shops and lights in the homes at Seoul. The modern Korean palace has been lighted for some time by electricity, and of late commercial plants have been established at Chemulpo and Fusan, while two plants under one management, supply light and power to Seoul, the capital. The Seoul company installs fixtures of a standard nature, charging a monthly rental for these, in addition to the regular current charges. This company is steadily importing and installing American fixtures. The company has also been installing many small motors, capable of running rice mills and other light machinery. It is believed that electrical fans will be used in Korea as soon as the natives able to purchase them become accustomed to the various uses of electricity. The American-Korean Electric Co., of Seoul, intends to introduce fans extensively during next summer, and electric flat-irons, warming pads, and other novelties will probably follow in due course. The steady market demand at present, however, is limited to motors and fixtures. The Oriental Consolidated Mining Co., operating at Unsan, has recently installed a modern and complete turbine electrical generating plant, capable of operating their stamp-mill machinery and mine hoists. Water is carried from a reservoir, with 111,599.231 cubic feet of available water, through a flume to the power house.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published Feb. 27th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1906 Patents

24,925, J. S. Raworth. In traction systems in which regenerative motors are used, it is possible that the voltage of the system may rise considerably above the normal voltage. In order that the machinery and instruments, connected to the traction mains, shall be protected from such excessive voltage or reverse current, a diverting circuit between the positive and negative conductors is provided, in which are a resistance and a switch operated by a relay. This switch is automatically closed by a rise in voltage or by a reverse current, and is also automatically opened on the restoration of normal conditions. One claim, one figure.

1907 Patents

440, British Thomson-Houston (*Allgemeine Elektricitats Ges.*). An improved method of starting alternating-current commutator motors of the type in which the armature is short-circuited in one axis and excites the motor field. At starting the short-circuited brushes are moved from their running positions until the motor speeds up, when they are moved back. The other brushes connected to the supply mains are kept stationary. Two claims, one figure.

3,060, A. D. Jones. The composition in the grooves of the positive carbon of the enclosed flame arc-lamp, which was described in Electrical Engineering, February 27th, 1908, page 299. The composition is a mixture of two parts of calcium fluoride (which alone would give the arc a whitish-yellow colour), and two parts of calcium tungstate (which alone would give the arc a purple-white colour). One part of sodium tungstate or potassium sulphate is added to steady the arc. The mixture is formed into a paste with a suitable binder, such as dextrine solution, and laid in the grooves of the positive carbon. The resultant light from the arc is of a brilliant yellow colour, and the colour and brilliancy are maintained, although the arc is enclosed. Two claims, no figures.

8,642. British Thomson-Houston (*General Electric Co.*). A method of connecting metallic filaments of tungsten, molybdenum, titanium, and similar metals to the leading in or supporting wires of incandescent filament lamps. The end of the supporting or conducting wire is fused round the filament by means of an electric arc. The fusing is done below the surface of a liquid, such as water, alcohol, or benzine, in which inert or reducing elements are liberated by the action of the arc. The liquid cools the globule of metal quickly, and ensures a good contact with the filament. Three claims, three figures.

9,294. H. L. Holden and G. B. Elphinstone. An improvement in the device described in Pat. No. 3,593, 1907, for automatically connecting the primary winding of a transformer to a source of electric supply, when current is required to be supplied by the secondary. This specification describes a relay switch which governs the main switch. Two claims, one figure.

11,071, Allgemeine Elektricitäts Gesellschaft. A method of automatically reducing the speed of electrically-operated winding gear (for instance, of a mine-cage when a passenger load is to be carried). The insertion of a resistance in the field circuit of the generator supplying the winding motor has the disadvantage that the regulating resistances in the same field circuit are then no longer correctly proportioned to give uniform acceleration and retardation. This method consists in exciting the generator field from a source of lower potential when a lower speed is required. The regulating resistances thus remain correctly proportioned and a uniform acceleration is obtained. The switching over from one source of potential to the other is performed automatically when the signal is given to the operator that a passenger load is to be carried. Three claims, one figure.

11,873. Siemens Bros. Dynamo Works and H. B. Poynder. A modification of the method of speed control of polyphase motors, as described in the specification for Pat. No. 10,007, 1907. (See Electrical Engineering, February 20th, 1908, page 285.) The low-frequency machine of the motor generator is a synchronous machine, and the main motor is supplied from this machine with a rotary field, either in the same or in the opposite direction to that in the stator. An increased as well as a decreased speed can thus be obtained, and further, by alteration of the excitation of the low-frequency machine, the power-factor of the main motor can be made equal to unity, or the motor can be made to take a leading current. Four claims, two figures.

19,856. Siemens Bros. Dynamo Works, Ltd. (*Siemens Schuckertwerke Akt.-Ges.*) An elastic device for insertion between an alternator and its prime mover in order to render it impossible for oscillations to be transmitted from the engine to the generator, or *vice versâ*. The elasticity or the natural period of vibration of the device can be altered by adjusting screws or similar means. One claim, no figures.

22,746. Siemens & Halske Akt. Ges. The preparation of metallic filaments for incandescent filament lamps. The metallic filament, for instance, of tantalum, is drawn through a solution or plastic mass consisting of a chemical compound of another difficultly fusible metal; for instance, tungsten. The coating thus obtained is reduced in an atmosphere of hydrogen by passing the coated filament through a tube, which is heated by an electric current, and through which hydrogen is passing. The coating is thus reduced to a metallic skin, and the final filament combines to a certain degree the favourable properties of both metals. Nine claims, no figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

555, Clark & Vlasto. Electric switches.
634, British Thomson-Houston Co. & Wedmore. Distribution systems.
634A, British Thomson-Houston Co. & Wedmore. Switches.
2,926, Armgur. Electric recording pyrometers.
3,025, Hope. Electric cut-outs.
3,226, Holmes. Electric heating apparatus.
3,305, Reuter. Electrical brakes for cranes.
3,543, Shellhamer. Electric heating-pads.
3,740, Wood, McLeod, & Lancashire Dynamo & Motor Co. Alternating-current motor control.
3,914, Reynolds. Electric furnaces.
3,982, Cowper-Coles. Electrolytic apparatus.
4,055, Meyer. Safety plugs.
4,125, Cabot. Wireless telegraphy.
4,128, Cabot. Systems of wireless telegraphy.
4,152, Peck. Systems of electrical distribution.
4,154, Cabot. Systems of wireless telegraphy.
4,833, British Thomson-Houston Co. & Garton. Regulation of motor-generator sets.
5,836, Franklin & Seyfert. Alternating-current motor.
5,952, Hill. Jointing and distributing boxes for cables.
7,048, British Thomson-Houston Co. (*General Electric Co.*). Magnetic wedges for dynamo armatures.
7,410, Haigh. Marine electric steering gear.
7,432, Cooper. Electric contact makers.
8,173, Milton. Inductor alternators.
9,172, Ingram & Hunt. Electric arc lamps.
9,572, British Thomson-Houston Co. (*General Electric Co.*) Incandescing bodies for electric lamps.
9,913, Hawkins. Recording meters.
10,861, Punga. Multiple circuit armature winding.
12,574, Lake (*Hallock*). Inductor type generator.
13,983, Little. Storage batteries.
14,752, Scott. Prevention of inductive disturbances in telephone circuits.
14,935, Torda & Torda. Distribution systems.
15,810, Pfanstiehl. Sectional induction coils.
23,416. Féry. Electrically-controlled pendulums.
24,751, Siemens-Schuckertwerke Ges. Commutators.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patents

16,366, Mayo & Houlehan. Motor starters.
26,435, Bosch. Electrical ignition apparatus.

1908 Patents

1,754, Lertourné. Electrical projectors.
2,195, Derain. Dynamos.
2,308, Siemens & Halske Akt.-Ges. Selecting receivers.
2,685, Fessenden. Receivers for wireless telegraphy.
2,955, Fessenden. Wireless signalling.

Expiring Patent

The following Patent expires during the current week, after a life of fourteen years:—

4,572, of March 5th, 1894. C. Adam-Randall. A telephone transmitter, consisting of one diaphragm, with two or more carbon contacts, each with independent battery and induction coil. The secondaries of the induction coils are in parallel and are connected to the line Four claims, four figures.

LOCAL NOTES

ARGENTINE: *Electric Lighting and Tramways.*—The *Review of the River Plate* states that an extension of three months has been granted to the concessionaires of the electric light station at Necochea, in which to complete the works. The latest reports from La Plata are to the effect that the question of the electrification of the tramways of that city will be definitely settled in a few weeks time.

Rosario Tramways.—The *Review of the River Plate* states that on January 15th the term expired within which the Rosario Electric Tramway Co. should have had the whole of its fifteen lines of tramways in operation, but only nine lines had been completed on that date, two were running over a portion of the route, and four were uncompleted. A communication has been received by the Council from the Tramway Co., however, stating that they expect to finish all the lines by April.

ASTON: *Electricity Supply Tariff.*—The committee have approved a new tariff for lighting purposes as follows:—For consumption not exceeding 150 units per quarter, 3½d. per unit; from 150 to 600 units per quarter, 3¼d. per unit; from 600 to 1,000 units per quarter, 3d. per unit; from 1,000 to 1,500 units per quarter, 2¾d. per unit; and 1,500 units, 2½d. per unit. During January, 91,243 units have been sold for lighting, 73,946 units for power, and 109,190 units for traction. The advance over the corresponding period of last year is 7,685, 9,212, and 50,430 respectively.

BARNES: *West London, Barnes, and Richmond Tramways.*—At a meeting of the Council last week it was decided to oppose the West London, Barnes, and Richmond Tramways Bill.

BEDFORD: *Mains.*—The Electrical Engineer has been authorised to make sundry connections on the low-tension mains, in order to equalise the pressure, at an estimated cost of £156.

BEXLEY: *"Free" Wiring.*—The Council is inquiring of the Local Government Board whether they would be prepared to sanction a loan under the Bexley Tramways Act, 1901, for the purpose of free wiring, &c.

BIRMINGHAM: *The Tividale Tramway Accident.*—At the inquest concerning the death of the conductor of the tramway car belonging to the Birmingham and Midland Tramways Joint Committee, which ran off the points at Tividale on February 20th, and overturned, the jury returned a verdict of accidental death. The driver of the car stated that when he took charge of the car, everything was in perfect running order. When he reached the loop at Tividale, however, the car swayed to the right and immediately toppled over. An examination of the track afterwards showed that both the front wheels had passed through the points, but that the two back ones were still in the points when the car went over. The driver maintained that he did not exceed the specified limit of eight miles an hour at this point; in fact, he had had to stop on account of a restive horse thirty yards from the spot where the car overturned. An official of the tramway company expressed the opinion that strain on the car, due to the fact that the two front wheels were off the rails, and the two back ones on the rails, caused the car to collapse. He could give no other reason for the car leaving the track except that it was driven at an excessive speed, but if, as the driver stated, he had had to stop thirty yards away, he admitted that it would be difficult to get up an excessive speed in that distance. An examination of the broken wheel of the car showed seven of the spokes fractured at the hub and at the rim. In summing up the coroner stated that there was not the slightest evidence that the car was being driven at a reckless rate, and the jury added a rider to the effect that a better class of wheel should be used upon the cars.

BLACKROCK: *Dublin and Central Ireland Electric Power Bill.*—The Urban District Council has unanimously decided to support the Dublin and Central Ireland Electric Power Bill, subject to the inclusion of protective clauses.

BOLTON: *Tramway Men's Holidays.*—The Tramways Committee has arranged that the motor men and conductors shall have seven days' holiday annually, and be paid for 60 hours in respect thereof.

BRADFORD: *Inspection of Electricity Works.*—A party of seventy municipal officials, with their ladies, were shown over the Corporation Electricity Works, by Mr. T. Roles, the City Electrical Engineer, last Friday evening.

Workmen's Tramway Fares.—A report has been prepared by Mr. C. J. Spencer, General Manager of the Corporation Tramways System, in regard to the facilities already offered to workmen upon the tramway service. At present there is a universal fare of 1d. before eight o'clock in the morning, the maximum distance which a passenger can travel being five miles, and the average 4·16 miles. Taking all figures into consideration, Mr. Spencer comes to the conclusion that at Bradford, workmen are given greater facilities than upon any other tramway system in the Kingdom, and he produced figures to show that any extension of these facilities will result in a considerable loss to the undertaking.

BRAY: *Bray and Enniskerry Tramway.*—A project for the connecting of Bray and Enniskerry by an electric tramway has been revived. Years ago the proposed route was surveyed for a light railway, but the venture did not come off. A Greenwich firm is now seeking for an Order in Council to construct an electric tram track between the places mentioned, and also for the lighting of Enniskerry. The proposed line will start at Bray Station, and proceed *via* the Dargle Road to Enniskerry, which is an alternative to the original proposal of running the line along the bank of the Dargle River. The engineering portion of the work does not present many difficulties.

BUENOS AIRES.—The returns of the tramway companies in this city for the year 1907 have been issued. There are now 325 miles of track (electric), and the total number of passengers carried was 218 millions, as against 176 millions in the year 1906. The German Electric Light Co. continues to show a heavy increase in the output for private lighting and power purposes. In 1907 the output was 27 million units, as against 22 million in 1906 for these purposes. The output for traction purposes in 1907 was 44 million units.

BURTON: *Extensions of Power Supply.*—With a view to the Corporation being able to supplement the already particularly good facilities they can offer in the way of cheap land, labour, fuel, &c., to new industries establishing themselves in the town, they have recently instructed Mr. P. J. Pringle, the Borough Electrical Engineer, to prepare estimates as to the best means of extending the generating plant and mains so as to deal with the supply of electric power on as favourable terms as possible. It is stated that twenty-three manufacturing firms have sent in inquiries with a view to establishing works at Burton, and that in the case of seven or eight firms, negotiations are now proceeding.

CARDIFF: *Tramway and Lighting Estimates.*—The estimates prepared by the Electric and Tramways Committee in respect of the tramways for the coming year show anticipated traffic expenses of £32,244; general expenses, £8,356; power expenses, £14,150; general repairs, £13,475; loan charges, £45,156; and special items, £588. The estimated income is £112,500 for fares; £14,250 sale of current to electric light department; advertising, £2,000; a total of £128,750, leaving a surplus of £13,779. In respect of the electric lighting department, Mr. Arthur Ellis anticipates a net profit of £1,594, after meeting expenditure, and loan charges to the extent of £43,905.

Charge for Tramway Power.—In a report dealing with the charge which should be made to the Electric Lighting Committee for energy supplied from the tramway power station, Mr. Arthur Ellis, engineer and manager, reports that this should be reduced, as this charged has become excessive during the past year, due to the plant installed on account of the electric lighting department becoming remunerative in consequence of the big load. Mr. Ellis states in his report that the present tramway station at Roath tends to become more and more a lighting station, and that eventually the time will arrive when the output for tramways will form a very small proportion of the total. He therefore recommends that the tramway and lighting departments should in future be charged at cost price for the actual number of units taken, plus a proper proportion for loan charges and depreciation, based upon the actual amount of capital expenditure for the respective purposes. The recommendation has been adopted.

CHATHAM: *Alleged Theft of Fittings.*—A. E. Tyrell was charged at the Chatham Police Court last week with stealing electric fittings from an unoccupied house, and was remanded.

COBHAM: *Electric Lighting.*—The Epsom Rural District Council has had under consideration an application by the Woking Electricity Supply Co. for consent to the company's application for a Provisional Order to supply electricity in Cobham. The company had been informed that the Council would agree, provided they paid the costs of the Council, amounting to £20. In reply to this, an offer of £10 10s. has been made, but the Council, having positively refused to give their consent upon such terms, an agreement has been come to by the company to pay a higher sum.

DUBLIN: *Employees' Provident Society.*—The fourteenth annual meeting of the Dublin Tramways Employees' Provident Society was held last week. During the year £1,498 was received in subscriptions, &c., and £1,263 was expended for sick benefits, medical aid, mortality allowance, &c.

DUMBARTON: *Commencement of Tramways.*—Messrs. J. G. White & Co., contractors for the Dalmuir-Balloch tramways, have begun laying the track.

DUNDEE: *Coal Costs.*—The committee appointed to investigate the increase in the coal charges at the electricity works met last week, when it was remitted to the convener of the Electricity Committee and Mr. Richardson to prepare a report on the matter. The question was first raised at a meeting of the committee by a report, in which Mr. Richardson stated that the coal costs had increased owing to the quality of the coal and the conditions under which it was supplied.

DUNFERMLINE: *The Electricity Scheme.*—A communication has been received from Sir Alexander Kennedy declining to

Digitized by Google

accept the appointment of consulting engineer to the Council as reported in our last issue, on the ground that his report recommending the transfer of the Council's Provisional Order to the Fife Electric Power Co. has been rejected.

GERMISTON (SOUTH AFRICA): *Electric Lighting and Trams.*—A scheme for the electric lighting and tramways has been submitted to the Town Council. It is probable that the opinion of an expert will be taken on the matter.

GUAYAQUIL: *Electric Tramways.*—Work on the new electric street-car line is being pushed forward as rapidly as possible. It is expected that a portion of it will be in operation shortly. The charter for this line was granted by the city some months ago to an independent company. It is believed that eventually the new company will either absorb the old company operating the mule lines, or be absorbed by it, and that the whole system will then be electrified.

HALIFAX: *Local Government Board Loans.*—The Electricity Committee have passed the following resolution:—That the Town Clerk be instructed to communicate with the Local Government Board protesting against the excision by the Board, from sanctions for borrowing powers, of wages of permanent workmen paid out of capital account, and that the electrical engineer be instructed to discharge, in future, permanent workmen when about to deal with work entailing capital expenditure, and then to re-engage such workmen as contractors.

HASTINGS: *Electricity Deficit.*—The Electricity Committee has reported that it anticipates a deficiency of £3,581 upon the electrical undertaking for the year ending March 31st, 1908. This includes the deficiency brought forward from last year, namely, £258, an increase in interest and sinking fund charges of £944, and an increase in working expenses of £242. The remainder of the anticipated loss is accounted for by reduced revenue. In their report the committee state that the reduced income from private lighting is almost entirely due to lower consumption, in consequence of the increasing use of metallic filament lamps.

HORSHAM: *Lamp Connections.*—The Electrical Engineer has reported that there are 13,825 lamps connected to the mains, and that a further 108 have been applied for. 1,400 have been connected during the past financial year, against 1,420 for the corresponding period of last year.

LEICESTER: *Tramway Statistics.*—In moving the tramway accounts for the year 1907 at the last meeting of the Corporation, Councillor Flint, Chairman of the Tramways Committee, stated that the past twelve months had not been a very favourable one for tramway receipts. The revenue account shows that 27,417,227 passengers were carried, giving a total revenue of £114,667. Working expenses amounted to £70,887, sinking fund to £12,029, interest £22,872, and income tax £968. Adding the bank balance, there is a net balance to be carried forward of about £10,538, which the Committee propose to add to the reserve fund, bringing this to £53,145. The working expenses have increased by £2,572, and coal by £800. In the Committee's report, the following statistics were given:—In 1901, when the tramway system was opened, the number of car miles run was 868,000, whereas last year, these amounted to 3,334,924. Similarly, in 1901, 10,000,000 passengers were carried, whilst in 1907 the figure, as already stated above, was 27,417,227. The average receipts per car mile were slightly less than 8d., which it is pointed out is well below the average of other towns.

LEYTON: *Electric Supply Charges.*—A memorial has been presented to the Council, bearing some 113 signatures, urging a reduction of the charges to consumers of electricity, the member who introduced the petition expressing a fear that unless they secured more advantageous terms, many of the shopkeepers at present using electricity would revert to the use of gas. The matter has been referred to the Electric Lighting Committee.

LLANDUDNO: *Sunday Tramways.*—A private meeting of the shareholders of the Llandudno Electric Tramways Co. has been held to consider the question of petitioning the Urban District Council to sanction tramways on Sunday. There seems to be a general consensus of opinion in the town that Sunday tramways should be sanctioned, although some difference of opinion exists upon the board of the company, as one of the directors opposes the proposal. This gentleman, Mr. J. Owen, has indicated his intention of resigning his directorship if the shareholders go so far as to apply to the Council. A sub-committee was appointed with a view to making the question a test question at the next election at Llandudno, and a poll is to be taken of the shareholders of the company.

LONDON: *London County Council: Electric Lighting Loans.*—The Finance Committee reported on Tuesday as follows, with regard to an application from the Islington Borough Council, for sanction to the borrowing of £23,304, repayable in 20 years, for extensions at the Borough Council's generating station in Eden Grove. "We have considered an application from the Islington Metropolitan Borough Council for sanction to the borrowing of £23,304, repayable in 20 years, for providing additional plant at the borough council's electric generating-station in Eden Grove. The proposed plant consists of a 1,500 kilowatt turbo-alternator with boilers, cooling tower, condenser, pumps, pipes, &c. The total estimated cost works out at the rate of £15 10s. a kilowatt, which we are advised is not unreasonable. It is 2½ years since the loan for the last turbine-driven alternator was applied for. We understand that the maximum output of the station (3,485 kilowatts) now exceeds the safe capacity, which is about 3,200 kilowatts. We are informed, moreover, that the maximum requirement during 1908-9 will probably reach 4,000 kilowatts. Having regard to the general financial position of the undertaking and to the largeness of the amount of the present application, we have obtained from the borough council a statement as to the probable financial results of the undertaking during the years 1907-8 to 1909-10 inclusive. We are still in communication with the borough council on financial matters connected with the undertaking, but as we are satisfied that the present application is reasonable, and as the borough council represents that the proposed additional plant is urgently needed, we are of opinion that sanction may be given forthwith to the borrowing of the amount applied for, repayable within the usual period of 20 years." This was agreed to.

On the advice of the Finance Committee the Council has sanctioned a loan of £2,394 to the Woolwich Borough Council, repayable in 20 years, for additional boiler plant at their generating station. This plant will partly supplement and partly replace existing plant, and the Borough Council proposes to repay to the London County Council the sum of £966 in respect of displaced plant.

Greenwich Footway Tunnel.—The L.C.C., at the meeting on Tuesday, approved a revised agreement to be entered into with the London Electric Supply Corporation for the supply of current at Greenwich footway tunnel. Hitherto the Company has charged for current at the rate of 2d. per unit for lighting purposes, and 1½d. per unit for working lifts, &c., but now they have agreed to reduce the price, subject to a four years' contract, to 1½d. a unit for lighting, and 1¼d. per unit for power. The saving to the Council will be about £345 a year.

Paddington.—At a meeting of the Borough Council on Tuesday, a report was presented by the Works Committee stating that since the question of improving the lighting in Harrow Road was last before the Council, the Metropolitan Electric Supply Co., Ltd., and the Gas Light & Coke Co. had lighted, as an experiment, certain lengths of the thoroughfare, in order to give a further opportunity of comparing the present and the proposed gas schemes with flame arc lamps. The cost of the present system of gas lighting, the report explained, is £198 per annum (*i.e.*, 66 lamps at £3). The Gas Light & Coke Co. now offer an improved system on the following terms:—66 lamps at £4 12s. 6d., totalling £305 5s. per annum. There would be no initial cost. If the lamps were taken over from the company at the end of five years, the Council would pay £164 (*i.e.*, 50s. per lamp); but, in the event of the proposed arrangement lasting for ten years, the lamps would become the property of the Council without payment. Under this scheme, the lamps would consist of two Kern burners in improved lanterns, one-half of the lamps being turned out at midnight. The Metropolitan Electric Supply Co., Ltd., offer a system of 24 flame arc lamps, at an average of £13 each, *i.e.*, £312 per annum. The initial cost would be about £170, as it would be necessary to erect new pillars on a section of the road where tram-poles are not available. This offer is made on the understanding that the arrangement would be in force for seven years. As in the case of gas, half the lamps would be turned out at midnight. The figures do not include any cost for the removal of the disused gas-lamp columns, as the value of the lamps, &c., would more than cover this. The committee reported that they had again come to the conclusion that the electric system was undoubtedly better than the gas for the purpose of improving the lighting and appearance of the thoroughfare, and that the Council would be justified in it, notwithstanding the slight additional cost in this case. The Council were also reminded that a memorial, signed by 200 ratepayers in Harrow Road, had urged the advantage of electric lighting, and it was announced that a further memorial to the same purpose had now been sent in containing 75 signatures. The Finance Committee called the Council's attention to the fact that the proposal opened the question of electric lighting for the whole borough, which would involve the Council in additional expense, and it was decided to adjourn consideration of the same until the next meeting of the Council.

Stepney.—The Thames Conservancy, at the meeting on Monday, refused an application by Stepney Borough Council for permission to construct, for the purposes of the generating station at Blyth's Wharf, an L jetty with overhead transporter, and to place two 48-in. suction pipes in the foreshore and river bed, with suction boxes at the outer ends.

MIDDLESEX: *Light Railway Undertaking.*—In connection with the revenue account of the light railway undertaking, the lessee company (the Metropolitan Electric Tramways Co.) claim that under the agreements they are justified in charging against the joint account each year as part of the working expenses a sum for the reconstruction and renewal, at some future date, of the tramways and light railway track. The Light Railways Committee, although agreeing that the provision might be prudent, expressed the opinion that the company were not entitled under the agreements to charge against the joint revenue any amount for reconstruction and renewal, but they agree as to the desirability of a joint reserve fund. The recommendation is, therefore, made that a joint reserve fund should be created out of revenue for the purpose of the recon-

Digitized by Google

struction and renewal of the light railway and tramway track in the future, subject to the fund being invested in an approved stock in the joint names of the County Council and the company, without earmarking it as between the tramways and light railways, and that the fund only be drawn on for reconstruction and renewal of tracks with the consent of the County Council. It is further recommended that any part of the reserve fund not expended at the end of the lease be divided in the agreed proportions of 45 per cent. to the County Council and 55 per cent. to the company, and that dividends received in respect of the reserve fund be invested from time to time and added to the fund. The Finance Committee is to report upon the financial proposals. The adjusted accounts for 1905 now show a net profit of £2,109, the Council's share of which is £949: in 1906 there was a profit of £2.299, the Council's share being £1,034: while the 1907 accounts show a profit of £9.200, the County Council's share being £4,140. The following figures of traffic receipts, car-mileage, and revenue per car-mile are interesting:—Traffic receipts: 1905, £140,000; 1906, £179,600; 1907, £239,600. Car-mileage: 1905, 3,286,712 miles: 1906, 3,975,463: 1907, 5,037,204. Earnings per car-mile: 1905, 10·64d.; 1906, 10·85d.; 1907, 11·64d.

NEW ZEALAND: *Electrical Enterprises.*—The Auckland municipality is installing an electric lighting plant, the material for which has been purchased chiefly in the United Kingdom. The authorised expenditure is £25,000, but already extensions are contemplated.

A company is being formed, called the Takapune Tramways & Ferry Co., with a capital of £100,000, for the purpose of constructing a tramway around Lake Takapune, a distance of ten miles. An American Consular report states that English concerns have men on the spot in New Zealand looking after this business, and urges electrical firms in the United States, if they wish to compete, to send competent salesmen.

NOTTINGHAM: *Lecture.*—Mr. W. H. Patchell gave a lecture at the University, Nottingham, last Saturday, on "The Sources of Economy in Power Production." The lecture was one of a series arranged by the Derbyshire and Notts Education Committee, and the Midland Branch of the National Association of Colliery Managers.

PENARTH: *Proposed Tramways for Cardiff.*—The District Council has received a letter from the solicitors to the Penarth Tramways Syndicate asking the Council's consent to the construction of a tramway to Penarth from Cardiff.

SOUTHAMPTON: *Light Railways.*—The Board of Trade has confirmed the Portsdown and Horndean Light Railway Order, 1908, authorising the construction of an extension of the Portsdown and Horndean Light Railway.

STOKE-UPON-TRENT: *Potteries Electric Traction Co.*—The Board of Trade have communicated with the Town Council with regard to their objections to a Provisional Order under the Tramways Act applied for by the Potteries Electric Traction Co., and North Staffordshire Tramways Co. The Council desire that their consent should be given to certain street works, and also to the manner in which these shall be carried out. The Board of Trade state that, having given careful consideration to the point, they see no reason to refuse the promoters the benefit of clause 5 of the Order which dispenses with its consent. Considerable objection was taken to this at the meeting of the Town Council last week, it being stated that if this decision be taken as a precedent, their roads could be taken possession of by the Tramways Co. without the local authority having any voice in the matter at all. Arrangements are being taken to oppose the Confirmation Bill in Parliament.

SUNDERLAND: *Collection of Accounts.*—It is stated by a local paper that owing to the large possible loss by the Corporation in connection with the account owing to them by Messrs. J. Laing & Sons, for electric power supply, the system of collecting accounts is to be revised.

Death from Electric Shock.—A young man named Nicolls, employed in the testing department at the works of Messrs. Bruce Peebles & Co., East Pelton, near Edinburgh, accidentally received a shock from a 6,000-volt testing circuit, and was immediately killed.

Dublin Local Section of the Institution of Electrical Engineers.—The annual dinner of the Dublin Section of the Institution of Electrical Engineers was held on Saturday evening, February 29th, in the Aberdeen Hall at the Gresham Hotel. A large number of the members were present, the chair being occupied by Mr. T. Tomlinson, chairman of the Dublin Section. Amongst the guests were Sir Charles Cameron, Mr. J. P. Griffith, engineer to the Port and Docks Board; Mr. J. H. Moore, President of the Institution of Civil Engineers of Ireland; Mr. R. M. Butler, President of the Architectural Association; Mr. Frank Gill, chief engineer of the National Telephone Co., formerly hon. sec. of the Dublin Section; and Mr. P. P. O'Sullivan, engineer to the Tramway Co. The toasts of the King, the Guests, Kindred Institutions, the Parent Institution, and the Chairman were duly honoured, and the programme was enlivened by the musical talent of a number both of the guests and the members of the Institution.

PARLIAMENTARY INTELLIGENCE

CAVEHILL AND WHITEWELL TRAMWAYS.—A long debate took place upon the motion for the second reading of the Belfast Corporation Bill in the House of Commons on Tuesday. This Bill, it will be remembered, embodies an agreement with the Cavehill and Whitewell Tramways Co., for the purchase of their undertaking for an agreed sum of £60,000. From the commencement of the negotiations there has been considerable opposition to the acquisition of the company's undertaking, although a poll of the ratepayers resulted in a large majority in favour of the Bill. Mr. J. Devlin, the Member for West Belfast, in moving the rejection of the Bill, set forth the circumstances which have led up to the opposition, and proposed a compromise of £40,000, provided the tramways company purchase and hand over to the Corporation a recreation ground on the lines of the road. Mr. J. Muldoon (Wicklow E.), in seconding the amendment, referred to the poll as "job," and contended that the transaction was too transparent for its provision to be set out in consecutive sections in the Bill, and consequently the promoters had hidden them away in a schedule. The real company with which they were dealing was the British Electric Traction Co. Mr. Emmett, the Chairman of Committees in the House of Commons, said that he was unable to form any opinion as to whether the Bill ought or ought not to have a second reading, as he knew nothing about the merits. After listening very carefully, however, to the debate, he thought that it would be meeting the interests of all parties if he made a suggestion that the Bill should be allowed to go before the Unopposed Committee of the House of Commons, and that the House should pass a resolution allowing petitioners against the Bill to be heard. After several other speeches for and against the Bill, a division was taken, when the second reading was rejected by 46 votes.

DUNDALK ELECTRICITY BILL.—Before the Court of Referees, on Wednesday, an application was heard for a *locus* against the Dundalk Bill by the Property Owners' Association of Dundalk. The Corporation, in order to put into force its electric lighting provisional order, has found it necessary to secure Parliamentary sanction for a loan, their existing borrowing powers (amounting to twice the rateable value) being almost exhausted. In order to oppose the Bill, a number of influential ratepayers came together, and, after an informal meeting, decided to call themselves the Property Owners' Association of Dundalk with the one object of opposing the Bill in question. The Committee, after considering the fact, decided not to grant a *locus* on the ground that the "Association" was not properly constituted, *i.e.*, had not been incorporated.

LONDON ELECTRIC POWER BILLS. In the House of Lords to-day, the Chairman of Committees will move that it is desirable that the London Electric Supply, London and District Electric Power, and the London (Westminster and Kensington) Electric Supply Bills be referred to a Joint Committee of both Houses.

PROGRESS OF ELECTRICAL BILLS.—The Wishaw Burgh Electricity Bill was read a first time in the House of Commons on Wednesday last week.

The London County Council Tramways Bill, which had been referred to the Standing Orders Committee, is to be allowed to proceed, subject to the deletion of clauses relating to certain lines in Hackney, for which the consent of the local authority had not been obtained.

The Croydon and District Tramways Bill and the West London, Barnes, and Richmond Tramways Bill were read a first time in the House of Lords on Wednesday last week.

The London County Council (Tramways and Improvements) Bill was read a second time in the House of Lords on Thursday.

London Underground Railways.—The station hitherto known as Tottenham Court Road, on the Charing Cross, Euston, & Hampstead Railway, is to be known on and after March 9th, as Goodge Street, and the name of the present Oxford Street station on that line is to be changed to Tottenham Court Road, in order to be the same as the station of the Central London Railway, which it adjoins.

London Electric Power Bills.—The first intimation of an important decision arrived at with reference to the future supply of electricity by municipalities within the metropolitan area is given by a circular letter which has been sent out from Islington to the other 27 Borough Councils. In this communication it is stated that on February 20th an informal private conference of representatives of Borough Councils who are electrical lighting undertakers was held on the subject of the Power Supply Bills now before Parliament, with a view to common action being taken thereon. The conference recommended strenuous opposition to the Bills in question, expressed the opinion that the development of the electricity supply of London could best be carried out by a combination of the existing undertakers, and urged that a conference of the electrical or consulting engineers of all the Metropolitan Borough Councils be held for the purpose of drafting a scheme on the basis referred to. The conference asks the various Metropolitan Borough Councils to endorse these recommendations.

TENDERS INVITED AND PROSPECTIVE BUSINESS

AUSTRALIA.—The Commonwealth Government calls for tenders by April 14th for the construction and laying of two cables between Victoria and Tasmania. £1,000 deposit is required, and full particulars and specifications may be inspected at the Commonwealth Government office, 72 Victoria Street, Westminster.

The Queensland Postmaster-General's Department invites tenders by April 20th for the supply and delivery at the Post and Telegraph Stores, Brisbane, of lead-covered cable.

The Camperdown (Victoria) Municipality has decided upon having an electrical installation, at an estimated cost of £8,000.

It is stated that tenders will not be called for with regard to the electrification of the Victorian railways, in accordance with Mr. C. H. Merz's scheme, until the middle of the present year.

BELFAST.—The Tramways and Electricity Committee invite tenders for twelve months' supply of stores, including electrical accessories. Particulars from the rolling stock superintendent, Tramway Offices, Napier Street, and tenders to the Town Clerk by March 16th.

BRISTOL.—The Docks Committee of the city and county of Bristol invite tenders for the electric lighting of the second tobacco warehouse, Cumberland Basin, and the maintenance of the work twelve months after completion. Applications to examine drawings and for specifications to be made to the Secretary of the Docks Committee (fee, £3, returnable). Tenders to be sent in by March 20th.

BURNLEY.—The Tramways Committee invite tenders for the supply of sundry stores and raw material used in maintenance for the year ending March 31st, 1909, including brass, gunmetal, &c., castings, brushes, washleathers, chamois, &c., cleaning cloths, cast-iron, brake blocks, and sundry castings, ironmongery, iron and steel, timber, nuts, bolts, and washers, india-rubber, car painters' requirements, and oil, grease, &c. Tenders close on March 10th.

The Guardians for the Burnley Union invite tenders for electrical supplies for the ensuing year. Tenders close on March 16th.

BURY.—The Corporation invite tenders for the supply, delivery, and erection of two 2,000-kw. turbo-alternators with exciters and condensers. Specifications and general conditions may be obtained from Mr. S. J. Watson, Electricity Works, Bury (fee £2 2s., returnable), and tenders to the Town Clerk by March 16th.

DUBLIN.—Tenders are invited for the supply of arc-lamp carbons. Particulars from the City Engineer, and tenders to the Town Clerk by March 11th.

ERITH.—Tenders are invited for stores for the year ending March 31st, 1909, including carbons, meters, lamps, cables, joint boxes, bitumen, insulating tapes, and compound and cut-outs. Specification and forms of tender from the Chief Electrical Engineer (fee £1 1s., returnable), and tenders by March 18th.

EAST LONDON (SOUTH AFRICA).—The Town Council has decided to abandon the existing electric power station, and proceed with the immediate construction of a new one at an estimated cost of £35,000.

EASTBOURNE.—A Local Government Board inquiry has been held with regard to an application for a further loan for extensions in the electricity department.

GLASGOW.—The redecoration and electric lighting of St. Ninian's Parish Church, is to be proceeded with in the summer.

The Tramways Department invite tenders for the supply and erection of two movable bridges over the Forth and Clyde Canal at Dalmuir and Kilbowie. Full particulars from the General Manager, 46 Bath Street, Glasgow, and tenders to the Town Clerk by April 15th.

HASLINGDEN.—The Haslingden Board of Guardians has engaged Messrs. Peers, Copeland & Cardin, of Manchester, to prepare a scheme for the electrical lighting of the new infirmary.

HEYWOOD.—The Electricity Department invite tenders for the supply, delivery and erection of the following:—(1) A Lancashire boiler, feed pump, steam, feed, and blow-off piping, water filter, and economiser; (2) steam engine and dynamo, condensers, air and circulating pumps, water-cooling tower, exhaust and circulating piping, return water and oil separator pumps; (3) lighting switchboard, alterations to traction generator, panels, combined booster and balancer set, and cable connections between machines and boards. Full particulars from the Consulting Engineer, Mr. J. R. Salter, Atherton, Lancashire, fee £3 3s. (returnable), and tenders to the Chairman of the Electricity Committee, Town Hall, Heywood, by March 16th.

HULL.—In connection with the renewal of old mains, the Electrical Engineer has estimated that the cost of the entire replacement of the New Town cables, based upon present prices, will amount to £6,075. The replacement of the Crompton bare copper strip system in the Old Town is estimated to amount to £12,130. The Local Government Board has sanctioned the borrowing of £6,959 for additional plant and mains; £8,088 in connection with the supply of electrical energy to the National Radiator Co.; £16,800 for actual and prospective expenditure from January 1st, 1907, and £4,140 for actual and prospective expenditure upon house service from January, 1907. The authorised periods of repayment are as follows:—17, 15, 20, and 15 years. The total amount is £35,967.

ILFORD.—The Council invites tenders for the supply of the following, required during the year ending March 31st, 1909, for the electricity department:—Meters, cables, incandescent lamps (carbon and metallic filament), arc lamp carbons, house service fuse boxes, joint boxes, coal. Full particulars from Mr. A. H. Shaw, Electricity Works, Ley Street, Ilford, Essex, and tenders to the Clerk by March 10th.

LANCASHIRE COUNTY ASYLUM.—Tenders are requested for the supply of electrical goods and supplies to the Lancashire County Asylum, Preston, for the year ending April 5th, 1909. March 13th and March 19 are the respective dates for tendering.

LEYTON.—At its last meeting the Urban District Council approved a list of 27 roads in which the conversion of gas lamps to electric lamps is to be proceeded with during the ensuing half-year, at an estimated cost of between £400 and £500.

LONDON: *London County Council.*—Tenders are invited for the supply and delivery of the points and crossings for junctions and cross-overs, &c., required for the reconstruction on the overhead trolley system of the existing tramways from Brixton Road to Camberwell Green. Full particulars from the Chief Engineer to the Council, fee £2 2s. (returnable), and tenders by March 10th.

St. Pancras.—Tenders are invited for the supply of arc lamp carbons for twelve months. Full particulars from the Electricity Offices, 57 Pratt Street, Camden Town (fee, £2, returnable), and tenders to the Town Clerk by March 23rd.

MANCHESTER.—The Electricity Committee invites tenders for the supply, delivery, and erection at the Stuart Street station of natural draught cooling towers. Particulars from Mr. F. E. Hughes, secretary to the electricity department, Town Hall (fee, two guineas, returnable), and tenders to the chairman of the Electricity Committee by March 10th.

NETHERLANDS.—H.M. Consul reports that the Town Council of Renkum have granted the concession to Mr. E. F. Blase, of Amsterdam, for the building of an electric tramway from Renkum *via* Oosterbeek to Arnhem, with lines to the neighbouring places, Waldfriede, Doornwerth, Wolfheze, and Ede, about 50 kilometres in all. Communications in regard to supplies should be addressed to Mr. E. F. Blase, Heerengracht No. 136, Amsterdam.

NEW ZEALAND.—The Napier Municipality is open to receive offers for the construction of electric tramways in that city.

STOKE-UPON-TRENT.—Tenders are invited for a 300-kw. steam generator (single acting engine and direct-current dynamo), together with a water-tube boiler and surface condensing plant. Full particulars from Mr. P. J. S. Tiddemann, Electrical Engineer, and tenders to the Chairman of the Electricity Committee by March 14th.

WAKEFIELD.—The Corporation invite tenders for a surface condensing plant. Full particulars from the City Electrical Engineer, and tenders to the Town Clerk by March 14th.

WALTHAMSTOW.—Two dozen lamp columns and 2½ dozen meter columns are to be obtained.

WATFORD.—Tenders are invited for the yearly supply of stores. Schedules and forms of tender from the Chief Electrical Engineer, and tenders to the Town Clerk by March 11th.

WEST HAM.—Tenders are invited for a 3,000-kw. 2-phase turbo generator. Particulars from the Engineer and Manager, 84 Romford Road, Stratford, and tenders to the Town Clerk by March 12th.

Anglo-Japanese Water Power Scheme.—An American Consular report mentions the establishment of an enterprise for the supplying of electricity for several cities in southern Japan. On December 6th, 1907, the minister of home affairs granted a license to the Anglo-Japanese Oi-gawa Hydro-Electric Power Co., which has for its object the supplying of electricity to Shizuoka and other cities on the Tokaido and neighbourhood by utilising the cataracts of the great Oi River. The company intends to develop water power of about 66,000 h.p. at Tamochimura, about 27,000 h.p. at a point between Ikama-mura and Hambaraumechi, and about 8,000 h.p. at Uchinakubi, in Yamanashi prefecture, respectively. The first, being the largest of the three works, will be postponed for some time. The second and third will be started in 1908 at an estimated cost of $5,000,000. The company is backed by a capital of $5,250,000, half of which will be equally subscribed by the British and Japanese promoters. It is further reported that the company will issue $2,500,000 worth of its shares for subscription.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA.—The Tasmanian Postmaster-General's Department has accepted the following tenders:—Lead-covered cable, silk and cotton insulated, with 104 pairs of 12½lb. conductors, £163, W. T. Henley's Telegraph Works Co., Ltd., Melbourne; hard-drawn copper wire, 70 lb. to the mile, £532, British Insulated & Helsby Cables, Ltd., Melbourne.

The New South Wales Postmaster-General's Department has accepted the following tenders:—Five additional subscribers' sections and one junction line section and extension in connection with new switchboard at the Central Telephone Exchange, Sydney, R. B. Hungerford, Sydney, £9,809.

The Victorian Postmaster-General's Department has accepted the following tenders:—Supply of 5,850 conduits of six ducts each, and 3,750 conduits of four ducts each, £1,643 18s. 1d., George Sweet, Carlton. The conduits are to be made of stoneware, and are to be manufactured in Australia. Half of the total quantity is to be delivered within three months, and the balance six weeks later. Supply of 50 telephones (wall sets), at £3 4s. 3d. each, £160 12s. 6d., W. McLean & Co., Melbourne.

BLACKPOOL.—The Electricity Department of the Corporation of Blackpool has placed an order with Ed. Bennis & Co., Ltd., Little Hulton, Bolton, for two stokers and self-cleaning compressed air furnaces for a new Lancashire boiler. This is a repeat order Ed. Bennis & Co., Ltd., have received from this Corporation, who have used "Bennis" stokers for about six years.

DUBLIN.—Since the North Dublin Board of Guardians have had under consideration the question of electric lighting at the North Union Workhouse, an offer has been received from the Gas Company undertaking to light the building by gas for an annual charge of £595, which sum will include the maintenance of lights, &c. The company also offer for a sum of £125 to fit up all the new lights necessary. The gas company, in a covering letter, state that this will show a saving of £405 over the present system if their offer is accepted, whereas the proposal to use electric light would only give a saving of £142 per annum. During the discussion upon this offer, several members supported the proposed electrical installation, and the matter was referred to the Lighting Committee.

FRODINGHAM IRON AND STEEL CO.—A repeat order for a 500-kw. generator for direct coupling to a gas engine running at 120 revs. per minute has been placed with the Lancashire Dynamo and Motor Co.

HULL.—Six tenders have been received for three high-tension dynamos required at the Sculcoates generating station. The tenders are as follows:—The Electric Construction Co., £2.812; Messrs. Crompton & Co., £4.099 10s.; Messrs. Greenwood & Batley, £5.305; Maschinenfabrik Oerlikon, £3.961; General Electric Co., £5.079; Lahmeyer Electrical Co., £4.591. The Engineer is to submit a special report upon the tenders.

ILFORD.—At the last meeting of the Urban District Council the Tramways Committee reported having further considered the question of extension of tramways in Cranbrook Road, and the estimated cost of the "Robrow" surface-contact system in comparison with that of overhead equipment. They recommended that the "Robrow" system be adopted for the proposed extension, and the tender of the Traction Corporation, Ltd., be accepted, subject to Parliamentary powers being obtained, and a satisfactory agreement being entered into with the company, embodying the whole of their guarantees.

LEYTON.—The Urban District Council has accepted the tender of the Brilliant Sign Co., Ltd., at £18 12s., for fascias for the Council's electric show rooms, and the tender of Selig, Sonnenthal and Co., at £66, for a shaping machine of 14 in. stroke, for the generating station. An order has been placed with Messrs. Mountain and Gibson for 250 wheel tyres for the tramway undertaking, to be delivered at the rate of 25 per month.

LLANDUDNO.—The tender of the Chloride Electrical Storage Co., for the supply of an Entz booster and battery at £607 and £1,255 respectively, has been accepted.

LONDON: *County Council Tramways.*—The Highways Committee have recommended that the offer of Messrs. Reid Bros., to lay cable ducts for the Hammersmith and Harlesden tramways and across Putney Bridge, at the rate of 23s. per lineal yard, including the reinstating of the pavement, be accepted, and that the Works Committee carry out this latter portion of the work.

Hampstead.—The Borough Council has accepted the tender of Pryke and Palmer for the annual supply of engineer's stores, and that of R. Ballard for the annual removal of ashes, clinker, and boiler refuse at 3d. per ton, to be paid to the Council.

Islington.—The Borough Council has accepted the following tenders for annual supplies for the generating station:—Engine-room stores, &c., Pryke & Palmer; arc lamps, carbons, and globes, Sloan Electrical Co., H. G. Mayer & Co., City Glass Co.; oils and lubricants, W. H. Wilcox & Co.; transformers and accessories, British Electric Transformer Co., Ferranti, Ltd.; iron, tools, belting, cotton, rope, &c., Pryke & Palmer; earthenware pipes troughs, bricks, fire-brick, fire-clay, &c., Young & Son; electricity supply meters and prepayment meters, Marples, Leach & Co., British Westinghouse Electrical & Manufacturing Co., Batt Electrical Co.; cables, British Insulated & Helsby Cable Co., W. T. Henley's Telegraph Works Co., Ltd.; electrical sundries, lamps, brushes, arc lamp parts, &c., Bryant Trading Syndicate, Ltd., General Electric Co., Heath & Johnson, Johnson & Phillips; terminal service and network boxes, British Insulated & Helsby Cable Co., Callender's Cable Construction Co.

Southwark.—The Borough Council has received the following tenders for 440 yards of 0·2×0·2×0·075 cable:—Union Cable Co. (accepted), £142 16s. 6d.; British Insulated & Helsby Cables, £176 2s.; Johnson & Phillips, £178 6s.; Callender's Cable & Construction Co., £179 5s.; Western Electric Co., £180; Siemens Bros. & Co., £183 12s. An order has been placed by the same authority with the British Insulated and Helsby Cables, Ltd., for a feeder pillar at £34 10s.

Westminster.—The Works Committee of the City Council have received the following tenders for the lighting required in connection with the Marble Arch Improvement Scheme:—Gas Light and Coke Co., high-pressure lamps similar to those fixed in Kingsway, £20 per lamp (for five lamps) for installation, and £16 9s. 6d. per lamp per annum for maintenance and lighting, subject to the usual increase or decrease in the price of gas; Westminster Electric Supply Corporation, flame arc lamps upon standards of the pattern now in use in the parish of St. George, Hanover Square, £40 per lamp (for five lamps) for installation, and £14 per lamp per annum for maintenance and lighting, subject to the Council undertaking any replacements or repairs due to accidents caused by third parties. The committee recommend the acceptance of the tender of the Westminster Electric Supply Corporation.

MUMBLES.—The Oystermouth Council having considered the offer made by Mr. A. H. Gibbings for a system of public electric lamps (ELECTRICAL ENGINEERING, February 27th, page 330), has decided not to accept the offer as the price works out higher than the present cost of public lighting.

WALTHAMSTOW.—The Urban District Council has accepted the tender of the Vulcan Boiler & General Insurance Co. for the insurance of eleven armatures at the lighting station against breakdown at an annual premium of £90. An Ohmer is to be purchased from Naider Bros. & Thompson for £16 12s., and steam coal is to be obtained from Rickett, Smith & Co. at 19s. 3d. per ton until the expiration of the present contract.

WIGAN.—The following tenders have been accepted for stores:—Electric lamps, the General Electric Co., and the British Westinghouse Electric & Manufacturing Co.; electrical accessories, The Armorduct Manufacturing Co., The General Electric Co., and The Electrical Co.; cables, Messrs. W. T. Glover, Ltd.

YARMOUTH.—Messrs. Bowers & Barr's tender for the maintenance of telephones, fire alarms, and electric bells at the workhouse, for three years at £21 12s. 6d. per annum, has been accepted.

Tramway Rating.—On Friday Mr. Justice Darling and Mr. Justice Phillimore, in the King's Bench Division, had before them in the Divisional Court a motion in which Mr. Page, K.C., moved on behalf of the Guardians of Hendon Union for a rule *nisi* for a writ of prohibition, calling upon the Justices of Middlesex to abstain from hearing a rating appeal brought before their court by the Metropolitan Electric Tramways, Ltd., whilst certain members of the Middlesex County Council were upon the Bench. The Metropolitan Electric Tramways, Ltd., have leased the Hendon tramways from the Middlesex County Council until August 6th, 1925, at a fixed rent, plus 45 per cent. of the net profits, these latter to be arrived at by deducting all expenses of running and management and rates. The Tramway Co. had appealed against their assessment for rating in the Hendon Union, and the appeal, in the ordinary course, would come up for determination by the Middlesex County Justices, but upon that Bench, stated counsel, there were various gentlemen who were also members of the Middlesex County Council, and he contended that it would be obviously improper for them, forming part of the corporate body which owned the tramways, and which must benefit if the Tramway Co. obtained a reduction in their rateable value, to act as judges in the appeal. Sir Ralph Littler was both Chairman of the County Council and of the Justices; Sir Francis Cory Wright was both a justice and the chairman of the Tramway Committee of the County Council, and there were other gentlemen who were both members of the County Council and Justices Mr. Page said that on an application for a respite of the appeal the point was raised before the magistrates, and they sat specially about three weeks ago and heard it argued. The magistrates not only came to the conclusion that the members of the County Council on the Bench might sit, but that, in fact, they would. Sir Ralph Littler, in giving the decision of the magistrates, said they were of opinion that there was no likelihood of bias on the part of the members of the County Council, and that the Justices were unanimous in wishing them to sit. Their lordships reserved their decision till Friday next.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f. port of arrival quoted on Tuesday night was £58 15s. to £59 5s. per ton (last week, £58 10s. to £59).

DISSOLUTION OF PARTNERSHIP.—The partnership between W. T. Garnett and R. R. Stell, carrying on business at Barkerend Mills, Bradford, as W. T. Garnett's Cable Company, has been dissolved. The business will be carried on under the same style by W. T. Garnett, by whom all debts will be received and paid.

LIQUIDATIONS, &c.—The Accumulator and Motor Construction Co., Ltd., is to be wound up voluntarily. Mr. Jesse Smith, of 79 Queen Street, Cheapside, E.C., has been appointed liquidator.

A meeting of the creditors of Messrs. T. A. Evans & Co., electrical engineers, of 14 Heathfield Street, Swansea, was held a few days ago at Swansea, when a statement was submitted showing liabilities amounting to £1,561 15s. 1d., of which trade creditors were scheduled for £478 2s. 7d. It was stated that the debtor commenced business about seven years ago, with a capital of £250. Of that amount £100 was his own money, and the balance was borrowed from his wife. The position two years ago showed a clear profit of about £130, after taking into account his own drawings. It appeared that the turn-over for 1905-6 totalled £1,667, with a gross profit of £555. Against this the trade expenses amounted to £235, and the debtor's drawings were £125, but it was impossible to get any definite figures as to the trading during the past eighteen months. He attributed his present position to his having taken a big interest in a colliery in South Wales, in connection with which he has expended approximately £600. At the present time the mine is flooded, and the landlord has taken possession. The cash creditors were made up of an overdraft at the bank of £550, who were guaranteed by third parties, and there were also three other claims in respect of money. On behalf of the debtor, an offer was made of a composition of 10s. in the £, payable as to 5s. in three months, and the balance of 5s. in six months, secured by certain of the debtor's local friends. After some discussion it was decided that the offer should be accepted, subject to the securities being found satisfactory to a committee of inspection. It was also resolved that if the outstanding creditors did not assent to the debtor's proposal within ten days, that a deed of assignment should be executed to Mr. E. H. Hawkins (Messrs. Poppleton & Appleby) and Mr. J. F. Harvey, Swansea, as trustees on behalf of the creditors. The committee of inspection appointed was as follows:—Mr. E. H. Hawkins, Mr. Howlett (G. Strauss & Co., Ltd.), and Mr. Jones.

MOTORS.—Messrs. Marples, Leach & Co. inform us that they have at the present time a particularly large stock of motors at their stores in London ready for immediate delivery. The list comprise some 80 continuous-current machines, ranging from ½ to 10 h.p., for various speeds and voltages. The self-starting single-phase motors are included from ½ to 5 h.p., and for 50, 60, 83, 93, and 100 cycles, as well as a series of fourteen 50-cycle high-speed single-phase induction motors. The two-phase induction motors are also for 50 cycles, and range up to 30 h.p. Those up to 3 h.p. are of the squirrel-cage type, but the larger machines have slip rings. The series of three-phase motors includes 25-cycle machines, as well as those for 50 cycles, and also range up to 30 B.H.P. Of course, provided they are not overloaded, the 50 cycles machines may be used on 60-cycle circuits. In addition to this large stock of motors ready for immediate delivery in London, we understand that a considerable number are in stock at the works, and can be delivered in a week on the receipt of an order.

Telegraph Traffic.—The lines of the Indo-European Telegraph Company were interrupted between Soukhoum and Kall on February 28th, but were again restored on the same day. The cable between Chio and Tenedos, belonging to the Eastern Telegraph Company, ceased operating on the 28th ult. Very few cables are now interrupted; the only ones requiring to be repaired or reopened are those to Venezeula, between Tangier and Cadiz and Port Arthur and Chefoo. The landline to Ohvaz, Persia, is also still down.

Tramway Frauds at Wigan.—A remarkable case of frauds committed against the Tramway Department of the Wigan Corporation was heard on Friday before the Wigan magistrates, when a young man named J. H. Higham was charged with aiding, abetting, and procuring a tramway conductor in the service of the Wigan Corporation to commit embezzlement and larceny. It was alleged that the accused, who was formerly a tramway inspector, had in fifteen cases prevailed upon conductors to join with him in defrauding the Corporation in respect of money taken as tram fares, using bogus tickets and a stolen punch. Several conductors had shared in the stolen money. The accused was sentenced to three months' imprisonment.

APPOINTMENTS AND PERSONAL NOTES

Some fifty applications have been received for the post of electrical engineer to the Sydney Council, which carries with it a salary of £900 per annum, from Australia, Great Britain, United States, and Japan. Mr. T. R. Johnson, the Chief Commissioner for Railways, has agreed to advise upon the merits of the different candidates.

The Hampstead Borough Council has decided to increase the salaries of officers connected with the Electricity Department as follows:—J. E. Barnes, assistant shift engineer, £78 to £85 per annum; F. V. Northey, assistant mains department, £110 to £125; J. Goodchild, assistant mains department, £112 to £118; F. E. Limbrey, outdoor inspector, £110 to £120 per annum.

The Leyton Council has agreed to increase the salary of Mr. Speight, who has been acting on probation as station superintendent since the death of the late superintendent, Mr. Noles, from £156 per annum to £180 per annum, the amount of the salary paid to his predecessor.

Mr. O. B. Richardson, the engineer in charge of the refuse destructor and steam plant of the Shoreditch electricity undertaking at Coronet Street, has been appointed engineer at Whiston Street, having charge also of the engines at Coronet Street. The vacancy filled at Whiston Street was caused by the death of Mr. J. Lawson.

Mr. G. Marconi has been appointed managing director of the Marconi Wireless Telegraph Company, Ltd., and of the Marconi International Marine Communication Company, Ltd., in succession to Mr. H. Cuthbert Hall, who has vacated these appointments.

Mr. Edison's Health.—The latest reports state that Mr. Edison's condition is now much improved, and that his complete recovery is now regarded as assured.

Underground Telephone Wires in London.—An application has been made by the National Telephone Company for the consent of the L.C.C. to the laying of short lengths of underground wires from main routes to distribution points. The company has on seven previous occasions, from 1897, onwards, applied to the Council for consent to the laying of underground works in London, and on June 1st, 1897 (pp. 618-9), provisional consent was given to the laying of underground cables subject to certain conditions which the company were unable to accept. In 1900, it being discovered that the company had executed a considerable amount of underground work without having in the first place obtained a licence from the Postmaster-General, and without having obtained the consent of the Council, proceedings were taken against the company with the result that they consented to an injunction restraining them from proceeding further with underground works without first obtaining the authority of the Postmaster-General and the consent of the Council. The company now point out that the telephone policy has been definitely settled by Parliament, and it having been decided that the telephone service of the whole country shall pass into the hands of the Postmaster-General upon the expiry of the company's licence the position of affairs is different from what it was when the Council and the company were last in negotiation. Moreover, in the agreement which was entered into in 1901 under which the Postmaster-General is to purchase the plant of the company in London on the expiry of the licence, and in the agreement which was entered into in 1905 dealing similarly with the rest of the country, the Postmaster-General is under obligation during the remaining period of the company's licence, to put down underground wires for the company in London and elsewhere, and there would be no point in the company doing this work itself, and therefore requiring the consent of the County Council, but for the element of delay which comes in. The Public Control Committee presented a report to the Council on Tuesday, saying that, as the removal of this delay would "accelerate," and consequently increase, the company's revenue, some portion of the benefit should be secured to the public. They recommended, therefore, that consent should be granted subject to the payment by the company of a sum of 2s. 6d. in respect of each station added in the London area. A number of restrictions as to the method of carrying out the work were also recommended in the report. One of these is that, in any streets where the Council anticipates constructing tramways, the cables shall be laid at least 3 ft. 6 in. below the roadway, and another that where cables are laid anywhere near tramways or other works of the Council, they shall be laid under the supervision of the Council, and the cost of such supervision shall be paid by the company. No boxes whatever are to be built without the express consent of the Council, which, if given, will only be given on full particulars and drawings being supplied showing the position of such box, and the size and construction thereof, and such consent shall be subject to such modification as to position, size, and mode of construction as the Council may require. The Council approved the recommendations in the report at their meeting on Tuesday.

CORRESPONDENCE

JANDUS ENCLOSED FLAME LAMP.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—In your Editorial Note, on page 298 of your last issue, on the Jandus Regenerative Flame Lamp, comparison is drawn between this and a previous patent. The essence of the patent referred to is a large globe, in which the circulation of gases is limited to a very small portion of the space. Every endeavour is made by means of depositing chambers, filtering devices, and combining chemicals, to secure a thorough elimination of the fumes before they again re-enter the globe.

The principle of the Jandus Regenerative Flame Lamp is exactly opposed to this. In this lamp the endeavour has been to keep the fumes in active circulation, and lead them again and again through the arc. The strong upward current, caused by the peculiar arrangement of circulating tubes, sweeps the sides of the enclosing globe, and keeps it clean, allowing a small inner globe to be used (an essential condition in enclosed lamps to ensure long burning hours).

So far as we are aware, no lamps have been made under the Blondel patent to which you refer. The lamp illustrated in ELECTRICAL ENGINEERING, Vol. II., page 853, is an open arc. In my early experiments I realised that an enclosed long burning flame lamp would be of little advantage unless a large economy was effected in the amount of chemicals used. The consumption of the positive carbon in the Jandus lamp is about 0·06 in. per hour; only a very minute amount of fresh chemicals can therefore be given off by the carbons, and the arc must depend largely for its supply of chemicals upon previously emitted chemicals.

From recent experiments I have proved that the regenerative principle plays a very large part indeed in giving the high light efficiency of the lamp. The arc is, in fact, constantly burning within a thick white mist of chemical fumes.

Yours very truly,

A. DENMAN JONES,
Works Manager,
The Jandus Arc Lamp & Electric Co., Ltd.

Holloway, March 3rd, 1908.

MISCELLANEOUS CITY NOTES

BRUCE PEEBLES & CO.—The following relating to the liquidatorship of Messrs. Bruce Peebles & Co. is given in the *Financial Times*:—Our Edinburgh correspondent telegraphs that in the First Division of the Edinburgh Court of Sessions yesterday answers were lodged for Messrs. A. Krauss & Sons, Bristol, to the petition of Bruce Peebles & Co., Ltd., for a winding-up order. The respondents state that they are creditors for £4,666, the balance of an amount agreed in October last in settlement of an action brought by Messrs. Krauss against the petitioners in connection with a contract. The petitioners, who accepted bills in favour of the respondents, object to the company being wound up voluntarily and to the appointment of Mr. Tait as liquidator, he being a director and having interests which conflict with the interests of the creditors. They also object to the appointment of Mr. Robertson, Durham, he being the nominee of the shareholders, and they desire the appointment by the Court of a neutral person as liquidator. They also ask for an order that the company should be wound up by the Court, and that the Court should appoint one official liquidator or a joint liquidator with Mr. Robertson Durham other than Mr. Tait. The answers were allowed to be received, and a note was also presented for Messrs Andrew Wilson Tait and James A. Robertson Durham to be appointed liquidators of the company with a supervision order. They state that it is expedient in the interest of the company that the liquidation should be placed forthwith under the supervision of the Court, and ask that their appointment be confirmed. The Dean of Faculty stated that the liquidation was a very large and important one, and it would be very much in the interests of all concerned if their lordships would grant an early hearing. This the Court agreed to do.

CALLENDER'S CABLE & CONSTRUCTION CO.—Mr. John Varley, of 11 Stanley Gardens, W., has been appointed a director of this company, to fill the vacancy caused by the death of the late Sir D. Evans.

CITY OF LONDON ELECTRIC LIGHTING CO.—The transfer books and register of members will be closed until March 18th.

GLOBE TELEGRAPH & TRUST.—A quarterly dividend of 3s. per share on the preference shares and 2s. per share on the ordinary shares has been declared.

INTERBOROUGH RAPID TRANSIT CO.—It is announced that if the flotation is assured, the company will issue twenty million dollars five per cent. mortgage bonds.

LIVERPOOL DISTRICT LIGHTING CO.—A dividend of 5 per cent. per annum for the half-year ended December 31st last, less income tax, is announced, making 5 per cent for the year.

MESSRS. VICKERS, SONS & MAXIM.—The directors recommend a final dividend of 2s. per share on the ordinary capital, making 15 per cent. for the year.

METROPOLITAN ELECTRIC TRAMWAYS, LTD.—Subscriptions have been invited during the week for a further issue of £173,800 4½ per cent. debenture stock at 96. The stock is redeemable at £105 in the event of liquidation or at the company's option after December 31st, 1930, at six months' notice.

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—The petition to the High Courts for confirming the resolution reducing the capital of the South London Electric Supply Corporation from £325,000 in £5 shares, to £250,000 in £4 shares, will be heard before Mr. Justice Nevill on March 14th.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The warrants in respect of the ordinary and preference share dividends for the year 1907 and half-year ended December 31st, 1907, respectively have been posted.

NEW PUBLICATIONS

"Stationary Steam Engines." By William H. Fowler. (Manchester: The Scientific Publishing Co.) 12s. 6d.

Transactions of the North-East Coast Institution of Engineers and Shipbuilders. February. (London: Andrew Reid & Co.)

"The Steam Turbine." By Robert M. Neilson. Fourth Edition. (London: Longmans Green & Co.) 15s.

Journal of the Institution of Electrical Engineers, No. 187, Vol. 40. (London: The Institution.) 5s.

Chilean Railway Electrification.—The American Consul at Valparaiso, reports that the Chilean Government has commissioned an American electrical engineer to study the feasibility of changing the first and second sections of the State railways for the use of electrical instead of steam power. It seems that the project might be very practical, as there are several good streams crossed by the railway lines that have their sources in the regions of perpetual snow along the Cordilleras that must have ample fall for limitless power possibilities. The first section connects Valparaiso with Santiago, and is about 100 miles long, and the second section extends from Santiago to Conception, and is about 350 miles in length. Double track is being laid on the first section. At present the coal bills for the State railways are heavy, since a large proportion of the coal used is imported at a high cost.

The Junior Institution of Engineers.—On Saturday, February 22nd, a visit was paid to King's College, London, for an inspection of the experimental apparatus, &c., in the engineering laboratory, the Siemens Electrical Engineering Laboratory, and the Wheatstone Laboratory, through arrangements kindly made by Professors D. S. Capper, H. Wilson, Ernest Wilson, and Waynforth. The apparatus includes various machines for testing materials; for thermodynamic work there are a 60 i.h.p. Marshall experimental compound engine; 20 kw. Belliss Siemens direct-driven set, Parsons steam turbine and direct-driven dynamo, Davey Paxman and Babcock-Wilcox boilers, Dowson suction gas plant, Crossley high-speed gas engine, condensing plant, various calorimeters, apparatus for flue and exhaust gas analysis, &c. Appliances are also provided for the determination of the cutting power of tools, and efficiency of machine tools, and belts and pulleys, and apparatus for determining the effect of blows on springs, and the resisting power of asphalte. The Siemens Laboratory is equipped with very complete and modern apparatus suitable for the practical instruction of students in every branch of electrical engineering. Direct current is obtained from the supply company's public mains, from a battery of Chloride cells, and from a Siemens 50 kw. generator of 500 to 550 volts. Alternating current is supplied from a Siemens 100 kw. eight-pole revolving field type of alternator arranged to give 1-, 2-, or 3-phase currents at frequencies ranging from 50 to 25; also from two Siemens generators, each of 10 kw. output, with a special coupling, which allows the phase displacement of the armatures to be altered. A complete tramcar equipment is provided, fitted with two 35 h.p. motors, with arrangements for testing draw-bar pulls, efficiencies, &c. In the Wheatstone Laboratory were shown the dark room for optical experiments, workshops for repairs, the celebrated George III. and Wheatstone collections, which include the Lodestone which belonged to Daniell, and was used by Faraday in his classic experiments on the induction of currents; the coils of insulated copper strip used by Henry in his experiments; the rotating mirror which Wheatstone employed in his experiments on the velocity of electricity along wires; the original Wheatstone bridge and resistance boxes, and Clerk Maxwell's dynamical model to illustrate the induction of electric currents.

COMPANIES' MEETINGS AND REPORTS

ABERDEEN SUBURBAN TRAMWAYS.—At the half-yearly meeting, Mr. G. J. Walker, chairman, in moving the adoption of the report for the half-year ended January 31st, said the free revenue amounted to £887, a sum that was, with one exception, the largest that had yet been earned by the Company in any half-year since its inception. The total amount at the credit of profit and loss account was £1,587, which the Directors proposed to carry forward meantime. Being now entirely within the Aberdeen Corporation's area of electric supply, the Company was entitled to demand a supply of electricity from the Corporation at the same rates as paid by other consumers for power purposes. If not, the Company would have to consider whether it would be cheaper to establish generating plant for the Company's own use. The report was unanimously adopted.

ASCOT DISTRICT GAS & ELECTRICITY.—The report for the half-year ended December 31st, 1907, shows a profit on the gas account of £2,225 8s. 5d., and a small loss of £14 on the electricity account. After providing for every charge against the half-year's working and interest on mortgage debenture stock, there remains a balance of £2,711 at the credit of profit and loss account, out of which the directors recommend the payment of a dividend at the rate of 5½ per cent. per annum on the share capital of the company, that the sum of £183 be set aside as a reserve for renewal of plant, and that the balance, amounting to £780, be carried forward. The electricity works were completed and opened by Sir Walter Palmer, Bart., on October 22nd, 1907, and since then consumers have been connected to the extent of 2,184 equivalent 8 c.p. lamps, and new applications are continually being made.

At the annual general meeting in London on Wednesday last week, Mr. J. Manwaring stated that the directors were well satisfied with the progress of the electrical portion of their undertaking up to date, and although customers had been somewhat slow in coming forward at the beginning, there were now connected to the mains the equivalent of 2,184 eight c.p. lamps, with other orders in hand. The company had been the first gas company to exercise electric lighting powers.

BLACKPOOL-FLEETWOOD TRAMROAD.—The report and accounts, given in our issue for February 6th, were adopted at the meeting on Thursday. The burden of the chairman's speech was the rating problem. He stated that their undertaking was the heaviest rated of all passenger-carrying undertakings in the United Kingdom, and everybody seemed to be against the company, even the Chancellor of the Exchequer. It was not the Blackpool rates that were increasing so much as those of the smaller councils outside, and the Thornton Council had threatened to take the question of the assessment of the company's undertaking to the House of Lords. A satisfactory feature of the year's working, the chairman pointed out, was that their working expenses were only 44 per cent. of the gross earnings, a lower figure than that achieved by any other tramway company in the country.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY.—The annual report for the year ended December 31st, 1907, states that the revenue account shows a credit balance of £31,718, which, with the balance of £9,146 brought forward, and £409 5s. balance of interest received, makes a total of £41,273. After deducting £1,726 11s. 8d. for interim dividend on the 7 per cent. cumulative preference shares, and £6,779 19s. 10d. interim dividend at the rate of 9 per cent. per annum for the half-year to June 30th on the ordinary shares, the directors recommend that the sum remaining, viz., £32,766 19s. 3d., be dealt with as follows:—To credit of depreciation account, £8,000; to payment of dividend on the preference shares for half-year ended December 31st, £1,716; to payment of dividend on the ordinary shares for half-year ended December 31st, at the rate of 11 per cent. per annum, making 10 per cent. for the year, £8,302; to credit of reserve fund account, £4,000; to directors' additional remuneration, £613; leaving, to be carried forward, a balance of £10,136. The death is recorded of Mr. William Page, who served the company as a director from its earliest years. Mr. Stanley Beeton has been appointed to fill the vacancy.

BRUSH ELECTRICAL ENGINEERING. The poll demanded at the meeting of the debenture holders (ELECTRICAL ENGINEERING, February 20th, p. 290), was taken on Thursday, when it was announced that voting to the amount of £21,371 had been given in favour of the proposed rearrangement of the debenture stock, and £16,256 against. As a clear three-fourths majority was necessary to carry the scheme, it was accordingly declared lost. A feature of the result is the very small number of debenture holders who voted.

CAMBRIDGE ELECTRIC SUPPLY.—The report and accounts for the year ended December 31st show that during the year there have been connected the equivalent of 2,269 8-c.p. lamps, making a total to date of 55,648. The number of units supplied has been 655,743, an increase of more than 59,000 units. A water softening plant and a new fuel economiser have been installed. An additional transformer substation has been built, and the supply mains have been extended in several directions. The accounts of the company show a total profit for the year of £8,292, to which is added £674 brought forward from 1906. After deducting debenture and other interest, £1,529, placing £1,500 to depreciation fund account, which will bring up the total placed to the credit of that account to £11,500, and writing £250 off suspense account, there remains a balance of £5,686. An interim dividend of 2½ per cent., absorbing £2,120, has already been paid, and the directors recommend the payment of a further dividend of 3½ per cent., making 6 per cent. for the year. This will absorb £2,968, leaving a balance to carry forward of about £598. The report was adopted at the meeting last Tuesday.

CHARING CROSS, WEST END, & CITY ELECTRICITY SUPPLY.—At the ordinary meeting held on Tuesday the report, already given in our last issue, was adopted. The Chairman, Mr. W. F. Fladgate, in speaking of the Electric Supply Bills now before Parliament, regretted that in the Bill to combine all the electric lighting companies they had not been able to include the Westminster Co. and four other West End companies, who had applied to Parliament for a Bill of their own. At a special meeting held subsequently the Bill referred to was agreed to. An article analysing the company's accounts appears on page 347.

COUNTY OF DURHAM ELECTRICAL POWER DISTRIBUTION.—The report to be submitted at the ordinary general meeting, to be held on March 10th, states that the profits of the year, together with the balance of £1,934 5s. 4d. brought forward from 1906, amount to £24,946, from which must be deducted interest on loans and debenture stock, £2,356, and interim dividend of 2½ per cent. on the preference shares paid in October last, £6,250, leaving an available balance of £16,341, which the directors recommend should be appropriated as follows:—In payment of a further dividend of 2½ per cent. on the preference shares, making a total dividend at the rate of 5 per cent. for the year, and of a dividend at the rate of 2 per cent. per annum on the amount called up on the ordinary shares, £10,958; in transferring to depreciation and reserve account, £5,000; in carrying forward to next year, £383. The total connections to the company's system at the end of the year, including the connections of its associated Parliamentary Company, the County of Durham Electric Power Supply Company, amount to 20,757 h.p., which, compared with the previous year's figure of 13,200 h.p., show an increase of 7,557 h.p. Of this increase about 4,000 h.p. were connected during the last months of the year, and have therefore been revenue earning only for a short period. The extensions to the general distribution system, referred to in the last report as having been delayed, became revenue-earning during the summer, and the revenue of the company has increased from £34,096 10s. 8d. in 1906 to £49,089 1s. 8d. in 1907, an increase of 44 per cent., which is satisfactory. The profits, however, which have resulted from this additional revenue have been considerably less, through the working costs being higher than were anticipated, by reason of the heavy rise in the price of coal. The directors report a satisfactory increase in the colliery demand for electrical energy, which the company is now able to take full advantage of, their power transmission mains being practically completed throughout the county. With the increase of connections, which still continue, the directors look forward to a material addition to the profits of the current year. The expenditure on capital extensions during the year has been £194,003, of which £173,933 represents the outlay on the company's account, and £20,070 the outlay on behalf of the Parliamentary Company, for which this company receives shares. Of this expenditure a large part only becomes productive during the current year. The balance of the ordinary share capital was paid up early in the year, making the whole of the authorised share capital fully paid up. To meet the developments of the company, an issue of £250,000 first mortgage debenture stock was made by the directors in December, and was over-subscribed. In consideration of the expenses of this issue, and in order to provide for depreciation, the directors have set aside a sum of £5,000 to depreciation and reserve.

THE MACKAY COMPANIES.—The annual report states that the receipts for the year amounted to $5,830,390, this income having been derived from investments in other companies amounting to $92,075,593. Disbursements were $3,655,216, dividends to shareholders, and $22,250 expenses, leaving a balance to be carried forward of $152,923. A surplus over liabilities of $880,470 is shown. Mackay Companies own the whole or part of the stock of 102 prosperous cable, telegraph, and telephone companies in the United States, Canada, and Europe, including the entire capital stock of the Commercial Cable Co., and the various companies constituting the land line system of the Postal Telegraph Co.

CITY OF BUENOS AYRES TRAMWAYS CO. (1904).—The report for the year ending December 31st, 1907, states that the annuity payable by the Anglo-Argentine Tramways Co., Ltd., has been received. The net revenue for the year has amounted to £65,744; interim dividends have been paid for the nine months ending September 30th, 1907, absorbing £46,500, leaving a balance of £19,244. The directors recommend that the balance be disposed of as follows:—The payment of a balance

Digitized by Google

dividend of 1s. 3d. per share (making 5s. per share) for the year ending December 31st, 1907, absorbing £15,500; £3,600 be transferred to general amortisation fund, and the balance of £144 7s. 5d. carried forward. The amortisation fund for the debenture capital, with accrued interest to date, amounts to the sum of £12,705 4s. 8d. The general amortisation fund for the redemption of the share capital now amounts to £17,903, included therein being a further sum of £130, the proceeds of sale during the year of a small strip of land in Buenos Ayres for railway development. The directors regret to have to announce the loss, by death, of two of their colleagues during the past year, Mr. Wells Hutchinson having died on June 21st, and Mr. Simpson Rostron on November 7th.

CITY OF CARLISLE ELECTRIC TRAMWAYS.—The report for 1907 shows a surplus of £1,784, being a decrease of £117 as compared with the previous year, and the balance of profit and loss account, after providing for debenture stock interest and debenture stock trustees' remuneration, is £632, which the directors recommend shall be carried forward.

CROSSLEY BROS.—The report for the year ended December 31st, 1907, stated that the amount at the disposal of the directors is £177,677, from which has been deducted a 5 per cent. dividend on the preference shares, and a 10 per cent. on the ordinary shares to June 30th, amounted to £38,600, leaving £79,077 for depreciation. The directors propose a further dividend for the half-year to December 31st at the rate of 12 per cent. per annum on the ordinary shares, making 11 per cent. for the year, carrying forward £34,773.

FIFE ELECTRIC POWER.—The annual general meeting was held last Saturday, in Edinburgh, Mr. Robert Russell, the chairman, presiding. The report showed that during the year there had been a steady increase of the company's business, and it was stated that the prospects of further business were most encouraging. The retiring directors were re-elected.

O. C. HAWKES.—The report for the year ended December 31st, 1907, shows that after allowing for bad and doubtful debts, and charging cost and replacements and repairs to the extent of £504, the net profit amounts to £13,149, including the balance brought forward from last account. Deducting directors' fees and balance and income tax, the net sum available for distribution is £12,048. An interim dividend of 5 per cent. on the preference shares has been paid. The directors now recommend a dividend of 5 per cent. per annum for the December half year, and on the ordinary shares, making 5 per cent. for the year (the dividend on the 5 per cent. preference shares for the December half year has already been paid), the balance to be carried forward is £3,548.

W. T. HENLEY'S TELEGRAPH WORKS.—The report for the year 1907 shows a net profit of £65,302. After payment of directors' and auditors' fees, and debenture interest, and making allowance for depreciation of buildings, plant, machinery, &c., there remains £50,330, making, with £22,320 brought forward from last year, a total of £72,650. The directors have transferred £10,000 to the reserve account, and recommend the payment of a dividend on the ordinary shares of 15 per cent. (less income-tax), of which an interim dividend of 5 per cent. was paid on September 2nd last. These payments will, together with the preference dividend for the year, amount to £49,000, leaving a balance of £23,650 to be carried forward.

HOVE ELECTRIC LIGHTING.—The report for the year ended December 31st, 1907, shows a net profit of £12,693, compared with £12,673 in 1906. The gross revenue shows an increase of £1,696, but the working expenses have increased by £1,676, due to the excess cost of coal and the additional outlay found necessary on repairs and maintenance. After payment of the final dividend for 1906, and setting aside an amount for renewals and depreciation account, there was a balance brought forward to the present year of £526, which, when added to the net profits from the present year, £12,693, makes an available balance of £13,219. After deducting debenture interest, the interim dividend at the rate of 8 per cent., paid in October last, and income tax, there remains a surplus of £8,055. The directors propose to place £4,000 to the renewals and depreciation account; to pay the accrued dividend and interest on the preference shares up to December 31st; to declare a final dividend, payable on April 15th next, at the rate of 9 per cent. per annum, making 8½ per cent. for the year; and to carry the balance, £780 10s., forward. The expenditure on capital account during the year has amounted to £2,893. With a view of replacing the capital expenditure taken from reserve fund, and investing this to provide for the future, 5,000 £5 preference shares were offered to the shareholders in November last, and 2,559 shares were applied for and allotted. The investments on account of the reserve fund now amount to £11,481. The meeting will be held on March 12th.

KENSINGTON & KNIGHTSBRIDGE ELECTRIC LIGHTING.—At the ordinary general meeting, held last Friday, the chairman, Col. R. E. B. Crompton, dealt at some length with the effect of the introduction of metallic filament lamps of much higher efficiency than the carbon filament lamp. For some time to come this might have an adverse effect on the consumption of electricity, but he said advisedly "for some time" because he felt that the saving would enhance the use of electricity as an illuminant, and the chances were that users would be more wasteful in the future than they had been in the past. Electric light was becoming more and more of a necessity and less of a luxury, and the companies should reap the advantage. He complained of the growth of rates and taxes, and said that if the sum which this company had to pay of £6,500 per annum could only be reduced by one-third, the directors would be able to pay a bonus of 2 per cent. upon the ordinary dividend. They had suffered in common with other electric lighting companies in regard to the increased cost of coal. In all the difficult circumstances of the past year he felt that the results presented would be regarded as satisfactory, for they were able to maintain the amount of dividend which they had paid to the ordinary shareholders for some years past, viz., at the rate of 10 per cent. per annum. He then dealt with the question of the bulk supply of electricity and the Bill which was jointly promoted by this and other West End electric lighting companies in the present session of Parliament, and which would be of benefit to all concerned. The report was adopted, and at a special meeting afterwards held the Bill was unanimously confirmed.

LANCASHIRE UNITED TRAMWAYS.—At the annual meeting, Mr. J. M. Henderson, who presided, said the profit for the year amounted to £12,789, and after payment of the debenture stock interest there was a balance of £289. This amount, with the credit balance brought forward from last year, had been written off the loss on the sale of motor-omnibuses. The receipts from the various tramways (other than St. Helens) comprised in the company's system, were £69,349, and the working expenses £56,499. The receipts per mile were higher than had been attained in any previous year. The working of the new St. Helens and District Tramways Co. had resulted in a profit, but it was not possible to distribute any of it in dividend, owing to the adverse balance of previous years. The report was adopted, and Messrs. Joseph Beecham and Robert Watson were re-elected directors.

LONDON ELECTRIC SUPPLY.—The annual meeting was held in London on Thursday. Explaining the cause for the dividend of 2½ per cent. instead of the 4½ per cent. declared last year, Mr. R. Benson, who presided, said that in addition to the increased price of coal, the revenue under the contract with the London County Council was very much less than had been anticipated. At the same time they hoped to counterbalance this by the supply to the London, Brighton and South Coast Railway, which would commence this year. The outlook for 1908 was much brighter, for they already had an increase in the receipts up to date. The total number of units sold since the beginning of the year amounted to 2,441,000, an increase of 20 per cent. over the same period of last year, and this, it should be remembered, was before the Brighton railway contract came into force. The gradual decline in the revenue which began in 1906, and which continued in 1907, seemed now to have ended, and, generally speaking, it must be admitted that the result has been less severe than might have been anticipated. During the present year it will be necessary to spend on capital account about £40,000, in order to complete works already sanctioned, but they had unused capital powers of £150,000 debentures, £100,000 preference shares, and £267,000 ordinary shares. With the Money Market in much easier condition, there should not be any difficulty in raising the necessary money. Dealing with the power supply problem in London, the Chairman stated he was convinced that the true solution lay in the combination and co-ordination, under some public control, limiting, for instance, the companies' dividends, similar to those of the gas companies, and giving in return some security against waste of capital or loss. It was partly with this object that the company had joined with others in depositing a Bill in Parliament this Session. The report and accounts, given in our issue for February 20th, were adopted, and at a subsequent special meeting the Bill mentioned above was approved.

MATHER & PLATT.—At the annual general meeting on Thursday, the report and accounts, given in our last issue, were adopted. Sir William Mather, who presided, said that their profits were the largest recorded in the history of the company, and it was satisfactory to be able to state that their foreign trade had expanded very considerably. The extra capital required to meet the increasing business had been provided out of a reserve, which was ample testimony to the wisdom of placing large sums to this fund, which now stood at £340,000. The directors recommended the appropriation of £5,000 to the employees' benefit fund, and also £1,000 to the Salford Royal Hospital, a principle which Sir William Mather said he heartily approved of.

METROPOLITAN ELECTRIC SUPPLY.—The report for the year ended December 31st, 1907, states that the capital expenditure, which at the end of 1906 amounted to £1,802,383, has now reached a total of £1,840,876, being an increase during the year of £38,493. The gross revenue for the year amounted to £178,684, as compared with £175,636 in 1906, being an increase of £3,048. As the revenue for 1906 included £5,178 for the remainder of the Marylebone business transferred on March 31st in that year, the total increase of revenue in the Company's areas during the year 1907 was £8,226. The working expenses, which in 1906 were £82,938, amounted in 1907 to £85,333, being an increase of £395. The Bill which was promoted last Session

Digitized by Google

by the London County Council for a bulk supply in and around London was jointly opposed by all the London supply companies, and was thrown out by a Select Committee of the House of Commons. The Bill deposited jointly by these companies was withdrawn. In the present Session of Parliament a Bill for bulk supply and other purposes has been deposited by certain persons seeking to be incorporated as the London and District Electricity Supply Company, against which this company has petitioned. The Company has also joined with certain other of the London Supply Companies in promoting a Bill for establishing a Statutory Joint Committee to deal with the supply of electricity in London and surrounding districts. This Bill, which contains provisions for the guarantee by the promoting companies of the interest on the capital of the Joint Committee to be authorised under the Bill, will be submitted for the approval of the shareholders at an extraordinary general meeting to be held immediately after the general meeting. The balance at the credit of the revenue account, before providing for depreciation, is £95,350. The directors have set aside £20,000 as an addition to the Depreciation and Reserve Fund, carrying to the credit of the net revenue account the sum of £75,350. This sum, with the balance brought forward from last account and other receipts, makes a total of £88,767. After deducting interest on debenture stocks and loans, dividend on preference shares and other charges, there remains a balance of £44,879. To this the Directors have added £21,000 from the undistributed balance of the Marylebone purchase money which was set aside towards the maintenance of dividends during the development of other business to replace the loss of Marylebone. This increases the balance at the credit of the net revenue account to £65,879. An interim dividend of three shillings per share (being at the rate of 6 per cent. per annum) on the ordinary share capital, amounting to £30,000, was paid on August 6th, and the directors recommend that a further dividend of three shillings and sixpence per share on such shares be now paid, making a total distribution for the year of six shillings and sixpence per share, or 6½ per cent. This will absorb a further sum of £35,000, and leave a balance of £879 to be carried forward to the next account. During the year new connections representing the equivalent of 49,758 8-candle-power lamps were added to the company's system, making a total connection at the end of the year of 755,116 lamps.

NEWCASTLE & DISTRICT ELECTRIC LIGHTING.—At the annual meeting on Wednesday last week, the report and accounts, given in our last issue, were adopted. Reference was made to the death of the late chairman of the company, Sir J. D. Milburn, Bart., and to the fact that the profits had not come up to anticipation, owing to the abnormal price of coal and the slackness of work in certain trades on the Tyne.

NORTHALLERTON ELECTRIC LIGHT & POWER.—At the annual meeting at Northallerton on Wednesday last week, the report and accounts, given in our last issue, were adopted.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER.—At the ordinary general meeting on Thursday, Mr. Henry St. John Winkworth (chairman of the company) presiding, the report and accounts given in our issue of February 20th were adopted. The Chairman stated that the lamp connections at the end of the year amounted to the equivalent of 160,380 8 c.p. lamps, an increase of 15,668. The consumers connected numbered 3,383, and the net revenue increased from £24,118 17s. 6d. to £27,067 19s. 2d., an increase of about 12 per cent. for the year. The units sold increased from 2,381,788 in 1906 to 2,946,607 in 1907, an increase of over 20 per cent. Seeing that the units sold increased more than 20 per cent. and that the net revenue only increased about 12 per cent., the consumers had benefited during the year to a substantial extent by the reduction of the price, whereas the average price for the year 1904 was 4·04d. per unit; it was now 3·23d. On the output for 1907 of 2,946,607 units, this represented a concession to consumers of about £10,000 as compared with the average price of 1904. Some inquiries had been made by shareholders as to the effect upon the business of metallic filament lamps. Although the extension of their use might lead to a temporary loss of revenue from existing consumers, the directors feel that whatever benefits the consumer must ultimately benefit the company. The capital expenditure during the year amounted to £42,281 15s. 8d., and deducting £5,500 placed to the credit of the depreciation account, the net addition to the capital account is £36,781 15s. 8d., which included about £20,000 in respect of the new power house. The increased earnings for the year amounted to £2,949 1s. 6d., a little over 8 per cent. on the capital expenditure for the year. The chairman concluded by saying that the directors have joined other London electric companies in promoting a Bill in the present session of Parliament for the establishment of a joint committee, and to make agreements for mutual assistance, and for the supply of energy in bulk to, and the taking of energy from, one another.

Mr. Henry W. Bowden, managing director, in seconding the motion for the adoption of the accounts, gave a few details of the position and prospects of the company, and an estimate of capital requirements during the next few years. The output for the year under review was 565,000 units more than the previous year, an increase of nearly 24 per cent., notwithstanding the unfavourable returns in the early part of the year. The cost figures, compared with 1906, are as follows:—Coal, 0·558d. compared with 0·542d.; works costs, 0·827d. compared with 0·837d; total costs, 1·32d. compared with 1·42d.; average price obtained, 3·25d. compared with 3·58d.; efficiency of distribution, 72·1 per cent. compared with 77·8 per cent. The latter decrease is partly due to transformer boosting and extra loss on feeders, some of which are fully loaded, more particularly between Lewisham and Catford, so that steps had to be taken to lay down ducts and cables, which could be worked at the existing pressure, but would eventually be utilised for an extra high pressure (10,000 volts) supply. When the work was finished he hoped that it would be the end of those heavy capital outlays which had had to be incurred from time to time. He felt somewhat strongly that the expenditure should be curtailed to the utmost, without absolutely closing the capital account. The cost of the extra high pressure supply is approximately £10,000, and he did not think for the next few years the annual expenditure for the ordinary growth of the business should exceed this figure. In regard to generating plant and costs, he thought it would be admitted that the company had progressed with the times when he stated that from the results already obtained during four months' working a saving had been effected in fuel alone of £700, or at the rate of £2,000 per annum. Considerable difficulty had been, and was still experienced in using Thames River water for condensing purposes owing to the collection of large quantities of vegetable matter, mud and other refuse, necessitating the use of special revolving screens or strainers and various other devices for either preventing the entrance of river refuse to or discharging it from the condensers. These difficulties had so far been successfully overcome at the new power house. The system adopted consists of sinking two iron chambers, which are connected to the river pipes in such a manner that the reversal of the water takes place daily, and this automatically washes out the chambers and keeps the condensers free from rubbish and permits of the full use of the syphon action at all conditions of the tide, thereby reducing the pumping power to a minimum. The efficiency could be observed by noting the vacuum on the turbines, which is invariably 95 to 96 per cent. of the possible or actual barometric pressure. The coal bill had recently been reduced to well under 0·5d. per unit (for a comparatively poor load factor), compared to 0·4d. per unit previously. The maximum demand was 2,550 kw., and they had connected or in hand orders which would bring this figure very nearly up to 3,000 kw. for the ensuing year, without reckoning on any orders which may be obtained for bulk supply.

The report and accounts were adopted after one or two complaints as to the smallness of the dividend upon the ordinary shares.

At a special meeting held subsequently the Bill in Parliament already referred to was approved.

TELEGRAPH CONSTRUCTION & MAINTENANCE.—The report for the year 1907 shows a net profit of £83,571, after charging the interest on the debentures. To this sum is added £104,308 brought forward from last year. From the total amount is deducted the interim dividend of 5 per cent., paid in July, 1907, amounting to £22,410, which leaves £165,470 to be dealt with. The directors propose to distribute a dividend of £1 4s. per share, together with a bonus of 6s. per share, being at the rate of 12½ per cent., and making, with the amount already paid, a total dividend for the year of £2 2s. per share, or 17½ per cent., free of income tax, leaving £109,445 to be carried forward to the next account. The report was adopted at the meeting held on Tuesday.

TORONTO ELECTRIC LIGHT & POWER.—The report for 1907 shows gross receipts of $1,039,716, compared with $899,578 for 1906, whilst expenditure amounted to $651,925, compared with $562,847. After meeting all charges, the net revenue amounted to $387,791, and a dividend of 8 per cent. has been declared. The sum of $150,000 has been transferred to reserve account, which now amounts to $500,000.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.—At the annual meeting last week, Mr. E. Boulnois presiding, the report and accounts, given in our issue for February 20th, were adopted. The Chairman stated that a contract was being entered into for the erection of their new station upon a site given by the London County Council to replace the Millbank Street Station, and arbitration proceedings were about to be commenced as to the amount which was to be paid. One of the reasons that a smaller dividend was paid this year, although the receipts were higher, was that the £15,000 carried forward in 1905 to equalise the dividend through the large increase in the assessment of the company's undertaking by the Westminster City Council has been exhausted. There was also a very large increase in the price of coal.

WIRRAL RAILWAY.—At the half-yearly meeting at Chester on Wednesday last week, Mr. T. H. Jackson, who presided, stated that the sum of £225,000 has been calculated as the cost of converting their lines to electric traction. The company has been carefully watching the result of electric traction upon other railways, but he did not think anyone could say that the results had been satisfactory, especially from the investor's point of view, and therefore before they attempted to raise the sum in question a system involving less capital expenditure and lower working expenses must be devised.

SUMMARY

The inquiry before Mr. James Swinburne, F.R.S., concerning the proposed Home Office Regulations for the applications of electricity in factories, was continued on Wednesday, Thursday, and Friday last week. Mr. G. S. Ram, Electrical Inspector to the Home Office, went through the whole set of proposed regulations and explained his reasons for advocating them. He was severely cross-examined with regard to the dimensions he gave for switchboard platforms and passage-ways. He admitted that a certain form of construction used by the Newcastle Electric Supply Co. was, if anything, safer than that provided in his regulations, although it was not in accordance with the regulation. He also expressed the opinion that practically none of the switchboards of the London electric lighting companies complied with the regulation, and that the same was the case with a number of municipal stations in the Kingdom. Mr. W. H. Patchell and Mr. J. F. C. Snell, who had been retained on behalf of the Home Office, expressed themselves in favour of this regulation. Mr. C. P. Sparks' principal objection to it was that it would necessitate expensive alterations in low-pressure switchboards. Under the Coal Mines Regulations, existing precautions may be continued until an inspector directs otherwise, and then there is right of appeal. Mr. Sparks thought that a similar rule should apply in the present case. Much discussion was directed throughout to the question whether existing work could be exempted from the proposed Regulations, and the process by which exemptions could be obtained or accorded. Mr. C. H. Merz, who represented Newcastle and Durham companies supplying nearly 150,000 h.p. of motors, and owning 96 sub-stations with a capacity of 100,000 kw., said that they were erecting 30 to 40 new sub-stations a year, and would be severely hampered by this regulation. Some of its provisions were unnecessary, and, on the other hand, important provisions for safety were omitted. Mr. W. W. Lackie said that to comply with the regulation he would have to abandon two sub-stations in Glasgow containing 9,000 kw. of plant at an expenditure of £120,000. Mr. A. A. Campbell Swinton opposed the regulation on behalf of 42 stations, including those of the Edmundsons' group: he had no objection to the rules for new work. Mr. H. Talbot, President of the Incorporated Municipal Association, supported previous objectors in desiring deletion of the dimensions in the rule applying to switchboards, and in desiring the exemption of all existing work. He argued that the passage-ways about a switchboard should be as narrow as possible to prevent their being used unnecessarily. Rule 12, stipulating that starting switches with no-voltage releases should be employed both for alternating-current

Digitized by Google

and direct-current motors, was then gone into, the natural objection being that they were quite unnecessary for a.-c. motors. Mr. Ram admitted that he had never seen a no-voltage release for an a.-c. starting switch, although they were obtainable. His suggestion that a no-voltage release for a whole works or group of motors might suffice, was characterised by the objectors as more dangerous than omitting the device altogether. The discussion on this regulation brought out points and examples of great interest to electric power-users, and was of a thoroughly technical character. Mr. Patchell said he used no-voltage releases successfully with large 440-volt and 2,000-volt a.-c. motors, but admitted that for small motors the apparatus would cost as much as the motor itself. Mr. Merz said he had 3,000 to 4,000 h.p. of a.-c. motors connected to his mains, none of which was fitted with no-voltage release. Mr. Merz characterised the Regulations as "stupid" and "dishonest," which raised a vigorous protest from counsel for the Home Office. The inquiry was adjourned until Monday next. (Page 381.)

THE high-tension transmission line and the transformer sub-stations of the Engelberg-Lucerne Power Supply Company are described. The power station was described in a previous issue. Along the edge of the lake of Lucerne the steel lattice poles are supported on brackets extending out from the shore over the surface of the lake, this unusual method of construction having been necessary in order to keep the high-tension wires away from the telegraph and telephone wires previously strung along the edge of the lake. Three sub-stations, for the double purpose of providing a local supply and of dividing up the line into sections, are situated between Obermatt and Lucerne. The chief sub-station is for the light and power supply of Lucerne, and another has been established at Kriens. (Page 389.)

AN apparatus for the electrical sterilisation of water has been put on the market in this country, in which a brush discharge is produced between plates of glass covered with tinfoil, by means of a small transformer. Air is drawn through between the plates and then thoroughly mixed with the water. (Page 392.)

ILLUSTRATIONS are given of the 11,000-volt overhead construction used by the Clyde Valley Electrical Power Co. (Page 393.)

A PAPER by Mr. W. B. PARSONS, read before the Institution of Civil Engineers last week, described the construction of the New York Rapid Transit subway. The greater part of this is of the shallow tunnel type for four tracks. (Page 394.)

THE first of the tunnels of the Hudson and Manhattan Railroad Co. under the Hudson River has been opened for traffic. Twin cast-iron tube construction is used, and the conductor takes the form of a single third rail outside the track. (Page 395.)

IN the report of the Chief Officer of the L.C.C. Fire Brigade, it is stated that the number of fires caused by defective electric circuits has fallen from 100 in 1906 to 88 in 1907. The total number of London fires attributed to electrical causes is given as 95, none of which were fatal, as against 348 due to gas and 329 due to oil and spirit lamps. (Page 396.)

A SUB-COMMITTEE of the Engineering Standards Committee, with Mr. C. H. WORDINGHAM as chairman, is engaged on the question of the standardisation of fuses. Among others who have been asked to carry out certain investigations for them is Prof. ALFRED SCHWARTZ, of the Manchester School of Technology, who, with Mr. W. H. N. JAMES, presented a Paper describing some of his results to the Institution of Engineers. These included determinations of the best length for fuses, and oscillographic records of the current and the rise of pressure at the moment of the circuit being broken. At the discussion in London, Mr. LEONARD ANDREWS and Mr. MORDEY referred to the magnetic blow-out effect of the wires leading to the fuses if they were arranged with this end in view; Mr. W. H. PATCHELL gave his experience of network fuses, and also referred to the difficulty of obtaining blocks that would carry different sized fuses; Mr. H. M. SAYERS advocated copper network fuses, replaced every August and December; and Mr. C. H. WORDINGHAM, chairman of the Fuse Standardisation Sub-Committee of the Engineering Standards Committee, deplored the difficulties of standardisation. Written communications were also received from Dr. GARRARD (who spoke at Manchester), Mr. E. B. SCHATTNER, and Mr. J. H. M. WAKEFIELD. At Manchester, Mr. W. CRAMP cast discredit on the old Preece fuse formula; Mr. C. F. SMITH said that the inductive drop was always more important than the ohmic drop in the case of blowing fuses; and Mr. S. J. WATSON expressed preference for aluminium fuses in section pillars, and objected to semi-enclosed fuses on switchboards. Dr. GARRARD'S remarks dealt mainly with the question of time-element, about which he has submitted a Paper to the Institution of Electrical Engineers. (Page 397.)

IN a Paper read recently before the Institution of Engineers and Shipbuilders in Scotland, Mr. H. A. MAVOR dealt with the advantages which could be obtained in large steam turbine-driven ships by increasing the speed of the turbines and decreasing the speed of the propellers, and described a form of variable-speed electrical transmission by which this could be accomplished. Induction motors are used in this system, which are started by allowing the "stator" to revolve and gradually arresting it by a mechanical brake. (Page 407.)

THE following books are reviewed in this issue:—"Thomas Alva Edison: Sixty Years of an Inventor's Life," by F. A Jones; "Universal Electrical Directory" (J. A. Berly's), 1908; "Local Government Board Annual and Official Directory for 1908." (Page 409.)

IT is pointed out under "Electrochemistry and Electrometallurgy" that the electrolytic refining of gold and silver is now carried out on a large scale in the United States and Germany. In the latter country the refining of silver was commenced so far back as 1881. In America the principal product to be refined is the gold and silver obtained as slimes in the copper refining baths, and the electrolytical method is fast ousting the chemical and metallurgical processes which have before been used. It is stated that an electrolytic plant for the refining of bullion is to be installed in London. The United States Mint at Philadelphia employ an electrolytic process. (Page 409.)

UNDER "Electrical Science," in the British and American Section, is a report of the first of Prof. J. J. THOMSON'S course of six lectures at the Royal Institution on electric discharges through gases, in which he dealt with the conductivity of air at ordinary pressure. In Papers abstracted in the Continental Section, RIGHI announces the discovery of a new type of radiation which he calls "magnetic rays"; NORDMANN proves that red light travels through space faster than blue light; and H. ABRAHAM makes a detailed study of the Ferrié electrolytic detector. (Page 410.)

AMONG the patent specifications published last Thursday is one by J. S. PECK, describing a combined frequency changing and flywheel load-equalising plant for use with slow-speed induction motors on intermittent loads. A further development in the method of fusing metallic filaments to supporting or leading-in wires is patented by the BRITISH THOMSON-HOUSTON Co. Other specifications of interest are those describing respectively the PUNGA multiple-circuit multiple winding for high-speed direct-current machines, and the magnetic wedges patented by the BRITISH THOMSON-HOUSTON Co. for retaining the conductors in the slots of induction motors. The patent by PRESTON &

Digitized by Google

Gill for the slipping-belt train-lighting system expires this week. (Page 411.)

Applications have been received by the Brighton Corporation, both from the Brighton Omnibus Company and on behalf of a London company, for permission to run electric omnibuses; the Watch Committee recommended that permission be given to the London company, but this was defeated at the meeting of the Corporation on Thursday. A tariff has been drawn up by the Dover Corporation in connection with the supply of electrical energy for the Admiralty Harbour. A report by the Highways Committee of the London County Council recommends the purchase of the Highgate Hill cable tramways. The Board of Trade has sanctioned a 6,000-volt transmission system in connection with the Stepney Borough Council's new generating station at Blythe's Wharf. The surface-contact system is proposed for the tramways at York. (Page 413.)

300 kw. and 400 kw. turbo-alternators are required by the Aston Manor Corporation; two 2,000 kw. turbo-alternators, with exciter and alternators, are required at Bristol; a surface condenser and cooling tower is required at Dewsbury; Lancashire boiler, generating set, switchboard, &c., are required as extensions to the Heywood Electricity Works. A long report has been presented to the Poplar Borough Council with regard to extensions involving an expenditure of £27,200. The Manchester Corporation require a 6,000 kw. turbo-alternator, and the Glasgow Corporation a 1,000 kw. turbo-alternator, in addition to motor generators, rotary convertors, and extra high-tension and direct-current substation switchgear. (Page 415.)

The contract for three-phase to direct-current converters in connection with the Avonmouth extension scheme of the Bristol Electricity Department, has been awarded to Messrs. Bruce Peebles & Co. at £3,647. The tender of the Lahmeyer Electrical Co., at £4,591, for the new generating plant at Hull, has been accepted. (Page 417.)

The Newcastle Electric Supply Co.'s accounts show a profit for the year of £87,379, and after meeting interest and debenture loans, &c., dividends upon the preference and ordinary shares of 5 per cent. and 8 per cent. respectively, and transferring £5,000 to depreciation, there is a balance of £2,025 carried forward. At the meeting on Tuesday it was stated that £1,000,000 additional capital was being issued through Lloyds' Bank. A new power-house is to be built at Dunston-on-Tyne, with an initial capacity of 30,000 h.p. At the meeting of the Metropolitan Electric Supply Co. on Tuesday, Mr. W. Harrison Cripps referred to the effect of metallic filament lamps upon the revenue, and mentioned an appeal against their assessment, which had resulted in a reduction of £10,000. (Page 418.)

In the House of Commons on Thursday, the London electric power Bills were referred to a Joint Committee of both Houses of Parliament. Mr. Harold Cox proposes on second reading to move the rejection of the Telegraph Construction Bill, for the reason that the House of Commons should be placed in possession of fuller information as to the financial result of the telegraph and telephone systems. (Page 419.)

Judgment in the Brighton sub-station nuisance case has been given in favour of the Corporation. (Page 419.)

We think that Mr. G. S. Ram, the Electrical Inspector to the Home Office, will be the first to admit, as a result of the first steps of the inquiry into his proposed regulations, that the experts who are responsible for the design of generating stations in this country, and the application of electric power in workshops, are even more fully acquainted than himself with the dangers that exist, and the safeguards that are necessary to guard against them. Our report of the proceedings on Wednesday, Thursday, and Friday last week occupies no less than seventeen columns, and is full of technical matter that will be read with interest by all users of electric motors, and from which more information can possibly be derived concerning the best practice in this direction than from the draft regulations themselves. It will be seen that it is the representatives of the "authorised undertakers" whose voices were heard most frequently, and to whose objections most attention has been directed; and that the individual power-user is apparently relying on the Commissioner's assurance at the commencement of the proceedings that his objections will receive consideration, even if he does not cross-examine the Home Office witnesses on the various points, and put in his own witnesses in support of his case. Although we do not desire that the inquiry should be unduly prolonged, we cannot but think that the owners of independent electric power plants, and those also who are only contemplating the adoption of electric driving, would find it to their advantage to press their claims into greater prominence. The authorised undertaker has three lines of defence. In the first place, he claims that no new regulations are necessary at all. Secondly, he maintains that if an interfering Home Office insists on imposing regulations, undertakers who are already obliged to observe the Board of Trade Regulations under the Electric Lighting Acts, should be exempt. If he is beaten back to this point he is separated from his ally, the independent power-user, although he himself may be entrenched in a stronger position. Lastly, he is able to take up his third line of defence, that should be absolutely unassailable, that existing work, whether it comply with the regulations or not, should not be disturbed unless the Home Office can show that it is absolutely dangerous, and under this plea the independent plant and the power-user will also receive some protection, although he may be harder hit than the larger electricity works when it is necessary to extend his installation. The Home Office representatives still say that they would not even be content to allow this very limited and reasonable exemption, and they argue that electricity works, sub-stations, and all works coming under the Factory Act, must alter their installations to conform with the new regulations, unless they can convince the local inspector (who probably will know nothing about electricity other than what he has read in Mr. Ram's regulations), that the existing safeguards are as good as, or better than, those in the regulations. On his inability to convince this gentleman, he is to be "entitled to make a statement in writing for submission to the Electrical Inspector," or, as Lord Robert Cecil sarcastically put it, his attention is called to the existence of the penny post. If the Electrical Inspector is likewise unconvinced, the electric power user or the owner of a generating station or sub-station, as the case may be, may be charged with committing a criminal offence if he neglects to alter his installation or works, even if no accident has happened and no actual danger has been proved. We need only take one example to show the absurdity of this. Mr. Ram has admitted that he has never seen an alternating current no-voltage release; in accordance with his regulations it is to be a criminal offence to use an alternating-current motor without this device; yet thousands have been safely in use without it for many years; it was also ad-

Digitized by Google

mitted by one of the Home Office witnesses that in the case of small motors, the cost of fitting the device would be as great as the motor itself. Yet this regulation with regard to the employment of a device still more or less in the experimental stage of construction is to be enforced, unless in every single instance a case for exemption can be made out.

FROM statements made in the discussion on a Paper dealing with "Fuse Phenomena," at the Institution of Electrical Engineers last week, we now know that the Engineering Standards Committee has taken in hand the standardisation of fuses. It may reasonably be asked by whom this standardisation has been requisitioned, and what good purpose it will serve when —if ever—the work is completed. Prof. SCHWARTZ, we were informed, is one of a number of gentlemen entrusted with experimental work for the Sub-Committee, and, if the other investigators are carrying out equally laborious tests and preparing equally voluminous reports, the final issue of standards by the Committee may be long deferred. This must be some satisfaction to those, like ourselves, who regard a general standardisation of fuses as entirely unnecessary. Prof. Schwartz's investigations have been directed to low-tension fuses below 50 amperes, and should, therefore, cover the ordinary house distribution-board fuse, for which at first sight standardisation would be advantageous. The present patterns of carrier-type fuses have very few disadvantages, and probably the only one is that there are differences in the carriers and clips supplied by different makers, so that the replacement of broken carriers may sometimes occasion delay. Standardisation of these might therefore be desirable, but apparently the work is being developed in quite a different direction, namely, the standardisation of a cartridge type of fuse. The extra cost of fuse replacements, which the employment of this pattern occasions in ordinary house-wiring work, is a strong argument against this, especially as, to judge by the tenour of Prof. Schwartz's remarks in introducing his Paper, the German fad of non-interchangeable fuses of different sizes which has been copied by some American makers is likely to be regarded as desirable practice. In ordinary house-wiring, the current for each way of the local distributing boards is 3 amperes on 200 to 250-volt circuits, and 5 amperes on 100 or 110-volt circuits. The Institution of Electrical Engineers' wiring rules as revised last year specify fuses to blow at 200 per cent. overload on these circuits; the previous Institution rules, to which a large number of buildings have been and are still being wired, prescribe 100 per cent overload; the Phœnix rules call for fuses blowing at 50 per cent. overload. Some local wiring rules issued by electricity undertakers have specified only 25 per cent., but this must not be seriously considered. We have thus no less than six sizes of fuse wires—to blow at 9, 6, 4½ amperes at 200 volts, and at 15, 10, and 7½ amperes at 100 volts. Of course, it will not be seriously suggested that non-interchangeable cartridge fuses with fuse-clips at different gauges or of different sizes are to be employed for all these six sizes, but this is sufficient to indicate the difficulties that will have to be encountered if the German method be followed, and the large and unnecessary cost that would be incurred in fuse-board alterations in the event of a change of voltage. If the fuses for house distribution-boards are to be absolutely standardised at, say, 6 amperes for 200-volt circuits and 10 amperes for 100-volt circuits, there may be something to say in favour of cartridge fuses of a standard size for this purpose, if they can be obtained of good and lasting quality at a cheap price, but more information is necessary with regard to these before we can consent to an official scrapping of the ordinary carrier fuse, which is still doing good service. If Prof. Schwartz had devoted the same energy which he has applied in the oscillographic study of fuses to a test as to the correctness of the rating of the various makes of cartridge fuse on the market, and the rapidity of ageing of these when run at 50 per cent. of their fusing current, he would have done still more useful and practical work. The cartridge fuse is still something in the nature of a surprise packet. When we come to the question of larger circuits, the non-interchangeable fuse and fuse-holder present more serious disadvantages. The main switchboards of public buildings would present a remarkable appearance if fitted with rows of cartridge fuses all of different outside dimensions, and the number of spare cartridges to be stocked would be an extra item of expenditure which would have to be considered. The use of these, moreover, would make it necessary to alter the fuse-clips on the board as extensions to the load on any circuit were made. A similar argument applies in the case of sub-stations and small generating stations in which magnetic cut-outs are not employed. We acknowledge that Prof. Schwartz has done work that intrinsically is valuable and interesting, but if we are to regard his Paper as a prelude to an academic and dogmatic standardisation of fuses which would add an additional burden to the long-suffering electrical contractor, we cannot bid it welcome.

ARRANGEMENTS FOR THE WEEK

THURSDAY, MARCH 12TH.

Institution of Electrical Engineers.

8 p.m Ordinary General Meeting at 25 Great George Street, Westminster. Lecture by Sir William Preece, K.C.B., F.R.S., on "America Revisited, 1907."

Electrical Contractors' Association: London Section.

8. p.m. Meeting at Restaurant Frascati, Oxford Street. Paper to be read :—"On the Comparison of Carbon and Metallic Filament Incandescent Lamps," by L. Gaster.

Rugby Engineering Society.

8 p.m. Ordinary Meeting. Paper to be read :—"The Systematic Design of Lines of Direct-current Machines, in Relation to the Use of Commutating Poles," by H. O. Eurich and F. P. Whitaker.

FRIDAY, MARCH 13TH.

Physical Society.

8 p.m. Meeting at the Royal College of Science, Imperial Institute Road, South Kensington. Among the Papers to be read is one by S. Russ on "The Distribution in Electric Fields of the Active Deposits of Thorium and Actinium."

Junior Institution of Engineers.

8 p.m. Meeting at the Royal United Service Institution, Whitehall. Paper to be read :—"Automatic Fire Extinction as Applied to Factories," by G. T. Bullock.

Royal Institution.

9 p.m. Evening Discourse by Signor G. Marconi on "Transatlantic Wireless Telegraphy."

SATURDAY, MARCH 14TH.

Royal Institution.

3 p.m. Afternoon Lecture II., by Prof. J. J. Thomson, F.R.S., on "Electric Discharges through Gases."

Birmingham and District Electric Club.

7 p.m. Meeting at the Colonnade Hotel, New Street, Birmingham. A discussion will take place, opened by Mr. R. Borlase Matthews, on "The Possibilities of Electrical Developments."

THE PROPOSED HOME OFFICE REGULATIONS

(Special Report. Strictly Copyright)

WEDNESDAY, MARCH 4TH.—SECOND DAY.

As stated in our last issue, Mr. Swinburne, the Commissioner appointed by the Home Office to hear the objections made to the proposed regulations for the use of electricity in factories (including generating stations and sub-stations), decided that he could not present an interim report on the questions of general principle that had been raised.

Mr. J. H. GRAY, counsel on behalf of the Home Office, said he desired to point out that the regulations proposed, really only defined what was already law under the Factory Acts, and which the Home Office could enforce at any time it thought fit. Therefore the regulations did not hamper the electrical industry in any way. It was not desired to make law what was not law before. As things were at present nobody was in a position to say whether they were complying with the law or not.

Mr. VESEY KNOX, K.C., counsel for the Newcastle Electric Supply Co. and the Cleveland & Durham Electric Power Co., said that the Home Office seemed to be under an entire legal misapprehension as to the effect of the regulations. If the Home Office view was the right one, then all that was proposed could be done equally well by memorandum.

Lord ROBERT CECIL, K.C., M.P., on behalf of the City of London Electric Lighting Co. and other companies, said that to suggest the regulations did not impose further restrictions was absurd. Dealing with the Board of Trade regulation A1 (reprinted in our last issue), he asked for some formal communication from the Board of Trade stating their intention to relinquish this. His view was that they could not relinquish it altogether.

Mr. GRAY said that no official communication had been received from the Board of Trade, but they had been assured that regulation A1 *quâ* factories would be abandoned.

Mr. G. S. RAM, Electrical Inspector of Factories, was then recalled, and went through the regulations in detail. We give his reasons for their adoption after each regulation below.

Mr. RAM first dealt with the definitions. These, he said, had been drafted in accordance with the general use of the terms, and he had kept as near as possible to existing definitions, for example, those adopted by the Board of Trade, but for obvious reasons the exact wording of the Board of Trade regulations could not be taken. With regard to the definition of "system," one objector wanted "pressure" instead of electromotive force; he agreed to this. With regard to the definition of "sub-station," it had been asked that single transformers up to 50 kw. should not come within the definition. The definition was based upon the definition of "electrical stations" in the Factory Acts, and therefore could not be altered. The definition of "switchboard" was regarded by some objectors as being too wide, and it was suggested that it might include a group of two or three lighting switches. He agreed that this might be the case, but it was immaterial because the definition was only used for the purpose of the regulation concerning switchboards. Similarly "switchboard passage way" had been objected to, it being stated that it should be limited to space in front or behind the switchboard. The suggestion had been made that in its present wording the definition could include telephone boxes, but the regulations did not refer to them, and therefore could not apply. With regard to the definition of "danger," there was no definition of this in the Board of Trade rules, and objections had been taken to the Home Office definition as being too wide.

Dealing with the exemptions, Mr. Ram said he had no comment to make upon exemption 1.

Exemption 2 reads that "Nothing in regulations 7, 8, 9, and 10 shall apply in electrical stations to any circuit, conductor, or cable used for conveying electrical energy for public supply." Mr. Ram now added regulation 28 in this exemption, and after the word "supply" the words "or tramway under licence or other statutory powers."

We give below the exemptions as altered and added to by the Home Office:—

Exemptions.

(*a*) Nothing in these regulations shall apply to any system the normal working pressure of which does not exceed 130 volts continuous or 65 volts alternating.

(*b*) Nothing in Regulations 7, 8, 9, 10, and 28 shall apply in electrical stations to any circuit, conductor, or cable used for conveying electrical energy for public supply or traction under statutory powers.

(*c*) Nothing in Regulation 12 shall apply to any motor of a motor-generator, or to any motor forming part of any electrical converter, regulator, or similar apparatus.

(*d*) Nothing in these Regulations shall apply on the premises of an occupier, being the consumer of an authorised electricity supply undertaking, to any service cables and apparatus belonging to or under the control of the authorised undertaker.

(*e*) If the occupier can show with regard to any requirement of these Regulations that the special conditions in his premises are such as to prevent danger not less adequately than if the said requirement were observed, that requirement shall be deemed to be satisfied.

The regulations were then gone through seriatim.

The Proposed Regulations.

Regulation 1.—All apparatus and conductors shall be sufficient in size and power for the work they may be called upon to do, and so constructed, installed, protected, worked, and maintained as to prevent danger.

This is based on regulation No. 1A of the Coal Mines Regulations, and is intended to cover various matters not separately dealt with. For instance, there is nothing in the Home Office Regulations as to the size of cables and wires to be used under different circumstances, nor for the protection of resistance frames and other things about a factory; these are intended to be covered by Regulation 1.

Regulation 2.—All cables shall be covered with insulating material, and further efficiently protected where necessary to prevent danger; or they shall be so placed and safeguarded as to prevent danger.

Mr. RAM pointed out that many objectors were under the impression that this regulation required all cables to be covered by insulating materials, but this was quite a mistake, because they had an alternative in the last line. The regulation did not prevent bare wires being used under proper conditions. The Institution of Electrical Engineers' Wiring Rule No. 12 (1905) provided that where the pressure exceeded 250 volts, the conductors must be completely enclosed in strong metal, sheathing or tubing, and no alternative or exception was allowed. Similarly, the Board of Trade Regulation A1, section (*a*)2 and B1, set up the same standard, but without any alternative. Board of Trade Regulation A1 (*c*)1 also provided that wires shall be enclosed in strong metal casing, and there was no alternative. Therefore, Regulation 2 was less stringent.

Regulation 3.—Every switch, circuit-breaker, and isolating link shall be:—(*a*) so constructed, placed, or protected as to prevent danger; (*b*) so constructed and adjusted as accurately to make and to maintain good contact; (*c*) provided with an efficient handle or other means of working, insulated from the system; (*d*) so constructed or arranged that it cannot accidentally fall or move into contact when left out of contact.

Section (*a*) is intended as a general protection, so that persons could not accidentally knock against a switch in a passage. Section (*b*) was, said Mr. Ram, obviously necessary to prevent overheating, and so that there should not be an arc in making contact. With regard to Section (*c*), it had been suggested by the Institution of Electrical Engineers, that there should be added the words "and so arranged that the hand cannot touch live metal." He had no objection to this. Section (*d*) was necessary especially in regard to isolating links. He had seen isolating links hinged at the top instead of at the bottom, the links being held up by the friction of the hinge, there being nothing to prevent them dropping. There were several objections to this section.

Regulation 4.—Every switch and circuit-breaker shall be so constructed as to be incapable of remaining in partial contact, or of maintaining an arc on breaking circuit.

Considerable modification was suggested in this to meet points raised by objectors. As an instance, however, of why the regulation appeared as it did, Mr. Ram mentioned one accident which he had had to investigate. There was an arc lamp circuit at 200 volts alternating current. While the lamp was burning, the lamp-man switched off the current, lowered the lamp, took hold of it, and got killed by shock. Examination showed that although the switch was off (it was a link switch, *i.e.*, two single switches connected by a link) the man had only broken the circuit on one pole; the other contact had either come off and gone back, or had never come quite off. At the time the regulation was drafted the Institution of Electrical Engineers' Rules of 1903 were in force, and rule 45 (*c*) appeared to fit this case so exactly that he had practically adopted it. Now, however, it was pointed out by some objectors that it was going too far to say that *all* switches should be incapable of remaining in partial contact. He was inclined to agree with this, and proposed an alteration as follows:—

"Every switch and circuit-breaker shall be so constructed that it cannot be inadvertently left in partial contact." The second part he was willing to alter as follows:—

"Every switch and circuit-breaker shall be so constructed that an arc cannot be inadvertently maintained."

Regulation 5.—Every fuse, and automatic circuit-breaker used instead thereof, shall be so constructed and arranged as effectively to interrupt the current before it so exceeds the working rate as to involve danger. It shall be of such construction or be so guarded or placed as to prevent danger from overheating, or from arcing or the scattering of hot metal or other substance when it comes into operation. Every fuse shall be of

Digitized by Google

such construction or be so protected by a switch that the fusible metal may be readily renewed without danger.

Some objectors suggested that it should be definitely stated what overloads are to be allowed, but he thought this very undesirable. With regard to the last sentence, there were still many old-fashioned double-pole fuses in use with a positive and negative fuse quite close together. When it was necessary to change a fuse, a man frequently made a short-circuit with his screw-driver, and was liable to injury. Such a fuse under these regulations would only be allowed if it were protected by a switch.

Regulation 6.—Every electrical joint and connection shall be of proper construction as regards conductivity, insulation, mechanical strength, and protection.

Mr. Ram had no comment to make upon this.

Regulation 7.—Efficient means, suitably located, shall be provided for cutting off all pressure from every circuit.

The main object of this regulation is that it shall be possible to make any part of an installation dead in case any work has to be done upon it. The regulation, said Mr. Ram, did not say that efficient means should be provided for cutting off all pressure from every circuit separately. It was conceivable in case of small installations that one main switch would serve the purpose. In case of larger installations, however, it would not be practicable to shut down the whole works, if any small thing was wanted to be done on one circuit; therefore some efficient means must be provided apart from the main switch for cutting off parts of the installation. The Institution of Electrical Engineers' rule 100 (of the 1907 edition) dealt with this point, and Mr. Ram thought this showed that the necessity for this regulation was recognised. The two regulations were not quite identical, however, the present one going a little further and stipulating that efficient means, suitably located, should be provided for disconnecting such circuits from the supply. These last two matters were not dealt with in the Institution of Electrical Engineers' rules.

Regulation 8.—Every circuit shall be efficiently protected from excess of current, and every circuit arranged to carry more than 750 watts shall be separately so protected.

This is based on Institution rule No. 21 (1907), and also on the Coal Mines Regulation No. 9, but it is claimed to be more clearly and concisely expressed in the present draft.

Regulation 9.—Where one point of a system is connected to earth, no single-pole switch other than a link for testing purposes shall be placed in any cable connected thereto.

This regulation is based on Institution Rule No. 16 (1907); the link for testing purposes is based on Institution Rule No. 17.

Regulation 10.—Where one of the main conductors of a system is uninsulated and bare, such as a bare return of a concentric system, no switch, fuse, or circuit-breaker shall be placed in that conductor, or in any conductor connected thereto, and the said conductor shall be earthed.

This is identical with Institution Rule No. 18 (1907). It was pointed out that the system referred to was not often met with, and Mr. Ram said he believed it was never allowed in an installation supplied from public supply mains, but there were instances with factory premises having their own generating stations. The danger was that the outer conductor might become charged to the full pressure of the circuit.

Regulation 11.—Every motor, converter and transformer shall be protected by a switch or switches, suitably placed, and so connected that all pressure may thereby be cut off therefrom and from any apparatus in connection therewith.

So far as motors are concerned, this regulation is based on the Board of Trade regulation A.1., sub-section (*a*) 3. The Home Office has added "converters and transformers." The corresponding Institution Rule (1907 edition) as regards motors is 91 (*e*), and it is also in Mines Regulations No. 34. The object of the regulation is that if any of these pieces of apparatus has to be attended to, it shall be possible to make it dead. An objection is made by the Coventry Corporation which Mr. Ram thought could be met. The objector in this case has a two-phase supply. The motors on consumers' premises are supplied with two-pole switches, and although the system was what might be called a three-wire system, the switch of the motor was only on the two poles, and it was pointed out that this was all that was necessary. Mr. Ram thought he could agree to this, provided the other wire was connected to earth at the generating station or sub-station, whichever it was, and he proposed to add these words:—"Provided, however, that where one point of the system is connected to earth, there shall be no obligation to disconnect on that side of the system which is connected to earth."

Regulation 12.—Every electrical motor shall be controlled by an efficient switch or switches for starting and stopping, so placed as to be easily worked by the person in charge of the motor. Every electrical motor rated at more than one-third of a horse-power shall be further protected by a release that will automatically break the circuit if the current is interrupted, unless the motor is incapable of re-starting automatically on the current being restored. In every place in which machinery is being driven by any electrical motor, there shall be means at hand for quickly stopping the motor.

No objection is made to the first point of this rule.

With regard to the second sentence, dealing with automatic circuit-breakers, Mr. Ram explained that this was really a mechanical requirement. It was not an electrical danger at the motor which was in view. Take the case of a motor driving machinery located on a different floor of the building. If the motor stopped and then went on again suddenly without warning, persons engaged at the machinery in every room might easily be injured. By means of an automatic circuit-breaker, if the current stopped from any cause, the circuit was broken, and even if the current came on again suddenly, the motor did not start. He proposed to add after the word "restored" the words "or no danger is involved by the automatic restarting of the motor."

With regard to the third sentence, this is intended to apply to places where there is a motor in the basement driving machinery on different floors, so that in a case of urgency, such as an accident in one room, for instance, it would be possible to stop the motor from that room. In some places Mr. Ram said he had seen motors locked up in a sort of hut or enclosure, and the man in charge away with the key in his pocket. In order, however, to obviate the necessity for stopping a motor, which might be inconvenient at times, he proposed to add at the end of the third section the words, "or the machinery."

Regulation 13.—Every flexible cable for portable apparatus shall be connected to the system either by efficient permanent joints or connections, or by a properly constructed connector. Every portable apparatus and its flexible cable shall be independently controlled by a switch conveniently placed. Adequate precautions shall be taken against shock, due to leakage or other cause, in all places where the person handling the portable apparatus is not insulated from earth. In such places, and in any place where the pressure exceeds low pressure, the switch shall be so constructed as to break the circuit on each pole.

In respect of this regulation the Institution of Electrical Engineers suggested that the words, "by efficient permanent joints or connections," should be deleted. They thought that a connector should be used on all occasions. Mr. Ram did not think he could accept this, because there were cases where a permanent joint was desirable. As an example he took the case of a tramway car repair shop, which would come under the Factory Act, where there was a 500-volt system with one pole earthed. He had seen several cases of portable lamps connected with flexible wires protected by flexible metallic tubes. This latter was permanently attached at each end, and connected to earth, and he thought in a case like that it should be permanently attached, because supposing the earth connection was at any time broken the flexible tubing would in itself constitute a great danger. If it could not be disconnected it was more likely to remain safe than if it could be disconnected.

Dealing with the second sentence referring to portable apparatus, Mr. Ram said this corresponds with the Institution Rule No. 76 (1907). The Institution and some other objectors made a suggestion that it should read "Every connector or group of connectors." He thought he could agree to that. Therefore instead of the words, "portable apparatus and its flexible cable," he proposed to substitute "connector, or group of connectors, for circuits not exceeding 750 watts in the aggregate." Also after the word "controlled," he proposed to add "on the live side."

The last part of the regulation, Mr. Ram explained, is aimed at the danger from shock from portable apparatus which may be leaky.

Regulation 14.—The general arrangement of switchboards shall, so far as reasonably practicable, be such that: (*a*) all parts which may have to be adjusted or handled are readily accessible; (*b*) the course of every cable may be readily traced; (*c*) conductors connected to different systems are kept apart and can be readily distinguished; (*d*) all bare conductors are so placed or protected as to prevent danger from accidental short-circuit.

One objector in regard to this section had suggested the addition of the word "well" after the word "kept." He thought this was a good suggestion.

Regulation 15.—Every switchboard having conductors normally so exposed that they may be touched shall be located in an area or areas set apart for the purposes thereof and suitably fenced or enclosed. No person except an authorised person, or a person acting under his immediate supervision, shall have access to any part of such area.

He proposed to add in the last line of the first part, before the word "suitably," the words "where necessary to that end." This meant that the switchboard need not necessarily be fenced, but it must be fenced if it could only be set apart by being fenced.

Regulation 16.—All apparatus appertaining to a switchboard and requiring handling shall so far as practicable be so placed or arranged as to be operated from the working platform of the switchboard, and all measuring instruments and indicators connected therewith shall so far as practicable be so placed as to be observed from the working platform. If such apparatus be worked or observed from any other place, adequate precautions shall be taken to prevent danger.

This was an endeavour to deal with the practice in some places of putting fuses and switches behind the boards. He

Digitized by Google

had known cases where rather than extend the board, switches, fuses, and instruments had been added at the back, and this was a most undesirable arrangement.

Regulation 17.—At the working platform of every switchboard and in every switchboard passage-way, if there be bare conductors exposed, or arranged to be exposed when live so that they may be touched, there shall be a clear and unobstructed passage of ample width and height with a firm and even floor. For low pressure and medium pressure the clear height shall not be less than 7 ft. and the clear width not less than 3 ft., and for high pressure and extra-high pressure 8 ft. and 4 ft. respectively. Bare conductors shall not be exposed on both sides of a switchboard passage-way unless either the clear width of the passage is double that otherwise required, or the conductors on one side are so guarded that they cannot be accidentally touched. Adequate means of access, free from danger, shall be provided for every switchboard passage-way.

The dimensions had been put into this regulation as a result of an examination of a large number of switchboards. He had seen switchboards with much less space and some with more space, and he thought that the regulation drew reasonable limits. The dimension of 7 ft. in height for medium pressure boards allowed a man to walk to the back of the switchboard upright, and even with his hat on. The width of 3 ft. clear did not appear to him to be excessive; it gave room for a man to walk along, and, if necessary, to work on the board. The distance of 4 ft. in width for high pressure boards was originally suggested by the report of the Dangerous Trades Committee about ten years ago. 8 ft. for height was given as being out of the reach of an ordinary man.

The latter part, dealing with bare conductors, was framed because with bare conductors on both side a man was liable to forget, and in this way was liable to touch the bare conductors and so get injured.

Regulation 18.—In every switchboard for high pressure or extra-high pressure :—(*a*) Every conductor within reach from the working platform, or in any switchboard passage-way, shall be so placed or protected as to prevent danger. (*b*) The metal cases of all instruments shall be either earthed or completely enclosed with insulating covers. (*c*) all metal switch-handles, and all metal rods connecting them with the switches, shall be earthed. (*d*) Every switchboard in continuous use shall be so arranged that the conductors thereof can be made dead in sections, and no work shall be done at any section unless that section be (*a*) made dead, and (*b*) so separated by permanent or removable divisions or screens, from all adjoining sections of which the conductors are live, that the work may be carried out without danger.

It had been pointed out in regard to section (*b*), that, although they might have a high pressure or extra-high pressure switchboard, the instruments nevertheless might be at low pressure if worked on transformers, and it was feared that the regulation would mean that such instruments would have to be protected whether they were at high pressure or not. Similar objections had been raised in regard to section (*c*). He proposed therefore to strike out the whole of section (*c*), and to substitute the following :—

"All metal handles of high pressure, or extra-high pressure switches, and, where necessary to prevent danger, all metal gear for working switches shall be earthed."

Paragraph (*d*) he regarded as a very important provision, and in a very large number of modern high-pressure and extra-high pressure switchboards, this requirement was already carried out.

Regulation 19.—All fixed coils, conductors, or terminals of generators, motors, transformers, or other apparatus, at high pressure or extra-high pressure, and within reach from any position in which any person employed may require to be, shall be so protected as to prevent danger.

Coal Mines Regulation No. 22 already covered part of this ground. One of the dangers often met with, and with which this regulation would deal, was with extra-high pressure motors and generators where the stator coils were not protected, leaving anybody to touch them.

Regulation 20.—Where a high-pressure or extra-high pressure supply is transformed for use at a lower pressure, adequate means shall be provided to prevent the lower pressure system from being accidentally charged above its normal pressure by leakage or contact from the higher pressure system.

This is based on Board of Trade Regulation A9. It had been suggested that this regulation should have been adopted entirely, but he could not do this, as the Board of Trade wording was restricted to the case of public electricity supply. The Home Office regulation applied to factory installations, and hence the difference. Instead of the Board of Trade words, "suitable automatic and quick acting means," they had the far more general expression, "adequate." It had been suggested by the Institution of Electrical Engineers that an alteration might be made in the wording, and that instead of the words "adequate means shall be provided to prevent," they should have "suitable provision shall be made to guard against," and that instead of the words "from being" substitute the word "becoming." He agreed to adopt this latter suggestion.

Regulation 21.—Adequate precautions shall be taken to prevent any metal other than the conductors from becoming electrically charged, and such metal shall be earthed where necessary to prevent danger.

This was framed in rather general terms. Other codes provided for the earthing of certain definite apparatus; thus the Board of Trade Regulation A1, sub-section (*a*)1 required the frames of motors of medium pressure to be connected to earth; sub-section (*a*)2, (*b*)1, and (*c*)1 of the same regulation required all metal cases for wires to be connected to earth, and that in the case of medium pressure, the metal cases of switch lamp-holders shall be connected to earth. Board of Trade Regulation A10 required that metal portions of transformers other than the conductors, shall be connected to earth, whilst Regulation A16 required that metal conduit pipes and casings containing any high-pressure electric lines, shall be connected to earth. Coal Mines Regulation 1c required the earthing of all metal coverings, armourings, and frames of generators, transformers, motors, &c., where the pressure is above low pressure. Coal Mines Regulation 47 required that metallic pipes for wiring, whatever the pressure, be connected to earth, and Institution Rule No. 24 required all metal sheathing or tubing to be earthed for low pressure. The Home Office Regulation, instead of specifying all these pieces of apparatus, was general in its application.

Regulation 2.—Adequate means shall be provided and used for preventing any conductor or apparatus from being accidentally or inadvertently electrically charged when persons are working thereon.

These provisions were very generally made in supply stations, sometimes by means of an actual locking switch, and sometimes by hanging up a notice. In other cases more elaborate precautions were taken.

Regulation 23.—Where necessary to prevent danger, insulating stands or screens shall be provided and kept permanently in position and shall be maintained in sound condition.

The Dangerous Trade Committee in 1897 made a recommendation in regard to the use of insulating mats for pressures about 350 volts alternating current, or 700 volts continuous current. Coal Mines Regulation No. 21 requires insulating floors or mats at medium-pressure switchboards, both in front and back. The words "stands or screens" did not mean that one was the alternative to the other. Whichever was required must be used, and if necessary both.

Regulation 24.—Portable insulating stands and screens, boots, and gloves, shall be provided and used when necessary to prevent danger, and shall be periodically examined by an authorised person.

The Dangerous Trades Committee recommendation No. 9 requires the use of gloves by persons working on live mains; gloves, mats, or shoes are also required for use above low pressure. The Institution of Electrical Engineers and others had suggested that the words "and gloves" be deleted. Whilst, on the one hand, engineers held that gloves should not be used in any circumstances, *i.e.*, that apparatus should be so safe that gloves are not necessary, others maintained that gloves are in certain circumstances necessary. He quite believed that there were conditions under which gloves should be used, and the regulation only required them to be used when necessary to prevent danger.

Regulation 25.—Adequate working space and means of access, free from danger, shall be provided for all apparatus that has to be worked or attended to by any person.

As examples for the need of this regulation, Mr. Ram mentioned that he had found the switches for working a motor placed behind a running belt; he had also found them placed on a wall, between which and the main operating the motor was a space having a drop of 12 or 15 ft., so that if the man in operating a switch received a shock, he would probably fall into this pit.

Regulation 26.—All those parts of premises in which apparatus is placed shall be adequately lighted to prevent danger.

Some objectors rather thought it necessary to have a light burning all the time. He quite agreed that this was unnecessary, but light should be available if it was wanted.

Regulation 27.—All conductors and apparatus exposed to the weather, wet, corrosion, or to inflammable surroundings or explosive atmosphere, or used in any process or for any special purpose other than for lighting or power, shall be so constructed or protected, and such special precautions shall be taken as may be necessary to prevent danger in view of that exposure or use.

Among the special apparatus under this regulation, Mr. Ram said he would include testing operations in a manufacturing works. He did not make any definite regulation, but merely stated that whatever precautions were necessary for safety should be taken.

Regulation 28.—Adequate periodical tests shall be made by an authorised person to ensure (*a*) that the insulation of all conductors and apparatus is duly maintained; (*b*) that no metal part of any apparatus, other than the conductors thereof, is electrically charged so that there is danger; and (*c*) that all earth connections are in order. Adequate periodical examinations shall also be made by an authorised person to detect any other defects from which danger may arise.

Bearing on this regulation, reference was made to Institution Rules 97 and 98 of the 1907 Edition, which provided for the

Digitized by Google

testing of installations before being put to work. Institution Rule 99 emphasised, in no unnecessary manner, the necessity for frequent systematic inspection and testing. It had been suggested by objectors that Board of Trade Regulation A6 should be substituted. This Board of Trade regulation provided that the leakage on the electric supply system shall not exceed one-thousandth part of the maximum supply current, but this rule was not applicable to individual installations. The limit of one-thousandth in many cases was not stringent enough. The Institution Wiring Rules allowed less than one-tenth of this amount; Coal Mines Regulation No. 6 was similar to the Board of Trade rule in allowing one-thousandth, but the case of mines was rather different. It was more difficult to keep down leakage in mines on account of water. He did not agree with the suggestion that the Home Office should adopt Board of Trade Regulation A6. The second paragraph of this Board of Trade regulation required a test once a week, which was much more frequent than he should presume to ask, but they would accept it if the objectors wished for it. The third paragraph of the Board of Trade regulation in question gave total exemption to the greater number of electricity supply undertakings, as most distribution from public mains was by the 3-wire system, having the neutral conductor earthed. If, therefore, the Home Office accepted the Board of Trade regulation, thousands of installations would never be tested at all. This regulation was one which he had that morning suggested should be added to the second exemption attached to the rules, so that it should not apply to any circuits in electricity works which conveyed electrical energy into the street and beyond.

Regulation 29.—No person except an authorised person, or a person acting under his immediate supervision, shall undertake any work where technical knowledge or experience is required in order to avoid danger.

It had been suggested by the Institution of Electrical Engineers that the contractor should be allowed to appoint the authorised person in certain cases. He thought the appointment of the authorised person should be considered in regard to the control of the danger. In the case of electrical sub-stations, accidents had occurred to contractors' workmen where he thought blame was attached to the occupier. He did not think it was fair, for instance, that supposing in an electrical sub-station a contractor was called in to do some work a man should be allowed to work without any supervision, in a dangerous place, merely because he was a contractor's man. In the case of an occupier having a factory or mill where he did not employ a competent person, but only a man for starting and stopping the motors, if anything went wrong assistance was obtained from an outside contractor, but the occupier should not be made responsible for the contractor's man being competent. In this case he thought it was the contractor who should appoint the competent person. He considered that the person who controlled the danger should be the person responsible for the safety of the workmen, and he thought that this difficulty might be got over by adopting the Institution suggestion with regard to the definition of "authorised person." They might make an addition to the definition of "authorised person," after the word "occupier" by adding, "or by a contractor or contractors for the time being under contract with the occupier." This addition, however, should be subject to an addition at the end of Regulation 29 as follows:—

"Where the contractor is employed and the danger to be avoided is under his control, the contractor shall appoint an authorised person, but if the danger to be avoided is under the control of the occupier, the occupier shall appoint an authorised person."

MR. GRAY, on behalf of the Home Office, pointed out that he did not think this would quite meet the objection, but no doubt something better could be suggested during the cross-examination.

Regulation 30.—Instructions as to the treatment of persons suffering from electric shock shall be affixed in all premises where electrical energy is used, other than for incandescent lighting at low pressure, and in all premises in which electrical energy is generated or transformed.

MR. RAM pointed out that this regulation was proposed by the Dangerous Trades Committee as regards electrical sub-stations for 350 volts alternating, and 750 volts continuous current, with the addition that all persons engaged in the works shall be practically instructed in methods of artificial respiration, &c. Coal Mines Regulation No. 13 required instructions to be posted in every transforming, generating, and motor house. The objectors to this regulation seemed to think that needless alarm would be caused by the display of instructions in the case of consumers connected to their mains. Personally he did not think this would be the case. At present, he pointed out, the Board of Trade required that under every motor a notice should be posted saying that no unauthorised person was to touch the motor. That was for medium pressure. The Home Office regulations did not require that instructions should be placed on every motor or about the place; one on the premises would comply. Such a notice might be placed at the entrance to the works where the Factory Act notice was usually placed.

Regulation 31. Every sub-station shall be of ample dimensions and substantially constructed of fire-resisting material; and shall be so arranged that no person can obtain access thereto otherwise than by the proper entrance, or can interfere with the apparatus or conductors therein from outside; and shall be provided with efficient means of ventilation and be kept dry.

The question of substantial construction was important. He had seen sub-stations for extra high pressure where it was possible to knock down the wall by leaning against it. With regard to access other than by the proper entrance, he had in mind a sub-station where the door was carefully locked, but the windows, three feet from the ground, were left open. The portion of the regulation with regard to interfering with the apparatus from the outside did not mean that they should not handle the switches from the outside. It was merely framed to prevent unauthorised interference. It had also been objected that the last provision, "shall be kept dry," could not in many cases be observed, and that it was impossible to keep some sub-stations dry, especially if they were underground, and that the words "as far as practicable" should be added. He did not, however, think that this was necessary or even desirable. While admitting that some sub-stations could not be kept dry, there was an alternative in the fourth exemption, namely, that if the sub-stations could not be kept dry they should take whatever precautions might be necessary. This might involve the use of gloves for handling the apparatus.

Regulation 32.—Every sub-station shall be under the control of an authorised person, and none but an authorised person or a person acting under his immediate supervision shall enter any part thereof where there may be danger.

Mr. Ram said there were many cases in which electrical supply authorities have similar regulations of their own.

Regulation 33.—Every underground sub-station shall be provided with adequate means of access by a door or trapdoor, with a staircase or ladder securely fixed, and so placed that no switchboard or bare conductor shall be within reach of a person thereon: Provided, however, that the means of access shall be by a doorway and staircase if (*a*) any person is regularly employed therein, other than for inspection and cleaning; or if (*b*) there is moving machinery therein, other than ventilating fans; or if (*c*) there is extra-high pressure therein.

An amendment had been suggested in regard to the first sentence, which he was willing to adopt, viz., that between the words "no" and "switchboard," the words "live part of should be put in.

At the close of Mr. Ram's examination-in-chief, it was decided that cross-examination should be first directed only to Regulation 17.

MR. VESEY KNOX, K.C., on behalf of the Newcastle Electric Supply Co., put a large number of questions tending to prove that the sub-stations of this company in the past was of a much more satisfactory and safe nature than any constructed under the proposed regulations of the Home Office would be. A plan of a sub-station built by this company was placed before Mr. Ram, in which it was shown that there were brick partitions and a hand-rail for the protection of the workmen, but in consequence of this the width of the passage way was reduced below the four feet for extra high pressure boards referred to in the regulation. Mr. Ram admitted that this form of construction was, if anything, safer than that provided for in the regulation, but refused to admit that the effect of enforcing the regulation would be to develop a design of switchboard which would be less safe than that now in vogue, and yet at the same time to enable the electrical supply authority to escape conviction. Asked as to his attitude towards such a sub-station built in the future, Mr. Ram said that he would consider it on its merits, and would probably agree to it. To his questions as to why, therefore, Mr. Ram wished to impose Regulation 17 upon the Newcastle Electric Supply Co., Mr. Vesey Knox could obtain no satisfactory reply. Mr. Vesey Knox therefore suggested that the regulation in question should stop at the word "floor," leaving out the prescribed limits. On the question of as to what is the best form of switchboard in practice, Mr. Ram said he preferred brick-chambers and expanded metal doors, with arrangements to isolate switches to enable the current to be cut off before the door could be opened. He believed such an arrangement as this had been installed in the sub-stations of Messrs. Armstrong, Whitworth & Co., in the Newcastle district.

Lord ROBERT CECIL, K.C., M.P., on behalf of the London electric supply companies, elicited the expression of opinion from Mr. Ram, that in the case of practically all existing London stations, none complied with Regulation 17, and counsel suggested, as a very good way out of the difficulty, the exemption of all these stations from the clause.

Further questions were put to Mr. Ram on behalf of the municipalities owning electricity works, to the effect that the same condition of affairs applied, and photographs of a switchboard at Glasgow were shown to illustrate this. In this case Mr. Ram said that he would require additions to protect men from accidental contact with the conductors in the passage-way. He admitted that, by the regulation all high-tension sub-stations would have to be a minimum of 8 ft. in height, and that this was not obtainable in many sub-stations. He realised a difficulty in this matter.

MR. SYDNEY MORSE, who represents a large number of supply companies, also asked that the figures and dimensions should

Digitized by Google

be omitted from Regulation 17, and that the undertakers should be left to provide "ample" passage-way. He also suggested the addition of the words "so far as is reasonably practicable," at the head of the whole set of regulations, making it apply to everyone. As an example of the difficulties which would be encountered under Regulation 17, as at present drafted, Mr. Morse instanced the generating station of the North London Railway Co., the switchboard of which backs on to the retaining wall of a public road, thus making alterations to the width of the passage-way on the switchboard impossible.

Dr. OLIVER, F.R.C.P., was called to give evidence in support of the fixing of the voltage limits at 130 volts continuous, and 75 volts alternating. He said he was the editor of a book on "Dangerous Trades," and had been a member of one of the Home Office committees which dealt with dangerous trades. His view was that there was considerable danger, both from the point of view of life and limb, between the voltages mentioned in the regulation and the pressure of 250 volts preferred by the objectors, although several factors were responsible for the degree of danger, such as the contact between the person and the current, and the condition of health of the person. He had seen rabbits and dogs killed by quite low pressures. In his judgment, the voltages selected by the Home Office were the best. Cross-examined by Lord Robert Cecil, witness stated he had never seen a case of human death by electric shock, and, although one or two cases of burning had come under his notice, he was unaware of the conditions. He thought it possible, by prolonged contact, that the pressures proposed in the Regulations might be dangerous.

THURSDAY, MARCH 5TH. THIRD DAY.

Mr. GRAY, referring to Exemption (*b*), said that in reference to the addition of the words: "or traction under statutory powers," which satisfied the objection of tramway companies, it had been represented to him that there were certain railway companies who generated electricity for the purposes of traction, who would not be covered by these words. He therefore proposed to add after the word "powers," "or for railway purposes." They had not had sufficient time to consider the point thoroughly, and it was quite possible that some modification of this might be necessary to meet the case.

Mr. F. W. FIRTH, electrical engineer to the Great Eastern Railway Co., asked whether this condition only related to traction purposes, and not to lighting and applications of power generally on railway premises.

Mr. GRAY said the intention was to apply the words to every application of electrical power by railway companies, but on the suggestion of Mr. Swinburne the exact wording of the alteration was adjourned.

Mr. RAM'S cross-examination was then continued by

Mr. A. M. SILLAR, representing a number of small electric lighting companies, asked that Exemption (*e*) should include the large number of small switchboards in existence, which were only sufficiently away from the wall to allow the terminals to be got at. Under the definition, these small spaces would become passage-ways, although they were never used as such in fact. In common with other objectors, Mr. Sillar asked that all reference to dimensions in Regulation 17 should be deleted. Mr. Ram replied that this question of dimensions had been very carefully discussed since yesterday, and he could say no more at the present moment than he had already indicated. At the same time he promised to consider the question further in the light of the cross-examination.

Mr. W. B. WOODHOUSE, for the Yorkshire Electric Power Co. and others, put the case to Mr. Ram of a two-storey sub-station on a consumer's premises, with the transformers on one floor and the meters, &c., on the other floor. The sub-station was locked up, and nobody entered it with the exception of the company's servants. Did the floor which contained the apparatus come within the definition of sub-station, and receive the benefit of Exemption (*e*)?

Mr. RAM thought the portion of the building in question would certainly be regarded as part of the sub-station.

Mr. COZENS-HARDY, who appeared for a number of factory owners, asked for an alteration in the definition of passage-way in the case of small boards, so that the small space usually available for a man to put his arm behind to get at the terminals should not come within the definition.

Questions were next asked on behalf of the WESTMINSTER CITY COUNCIL with regard to the evidence and accidents upon which the regulations were based, and also for a statement of what electrical accidents had been dealt with in the past by the Board of Trade, and those dealt with by the Home Office.

Mr. GRAY, on behalf of the Home Office, replied that he did not intend to rely upon the frequency or scarcity of accidents in relation to the formation of these regulations, and his advisers were not desirous to give them, as they felt it would only tend to lengthen the inquiry without assisting the Commissioner in any way.

Continuing, Mr. GRAY gave some particulars with regard to the dimensions specified in some foreign regulations. The French regulations, he said, prescribed that for high pressure the width of the switchboard passage-ways shall be one metre, and the height two metres, and that there shall be a locked door. No dimensions were given for low pressure. These regulations were published in July, 1907.

In the German regulations, the width was fixed at one metre and the height at two metres. If the wall had naked conductors the passage must be two metres wide, and the space must be divided by a railing.

The Swiss high-presure regulations stipulated that the height should be two metres 20 centimetres, when there were conductors on the ceiling, and two metres when there were no conductors there. The width for high pressure was one metre, and for low pressure 80 centimetres. When no conductors were on the wall, the width for high pressure was one metre 50 centimetres, and for low pressure one metre 20 centimetres.

The advisers of the Home Office, continued Mr. GRAY, regarded these dimensions as too small, but nevertheless it was thought that this information should be in the hands of the objectors. All the regulations referred to were Government regulations, and low pressure was defined as 600 volts continuous current, or 150 volts alternating current, high pressure being all pressures above these.

Mr. RAM, re-examined, said he had based his figures in Regulation 17 upon the report of the Dangerous Trades Committee, and also upon examples of switchboards which he had seen. Existing works were sufficiently safeguarded by the exemptions, but it was necessary that there should be uniformity of practice with regard to future works, and the dimensions given in his opinion would ensure safety from danger so far as this can be done by spaces. The Newcastle sub-station referred to on the previous day would come under Exemption *e*, but he could conceive cases in which such a form of sub-station might not. With regard to the sub-station mentioned belonging to the Glasgow Corporation, this would not come within the exemption without additions, but these would not be impossible to make, nor would they involve a great deal of expense.

Mr. SWINBURNE asked for a definition of the legal position with regard to Regulation 17. For instance, suppose a switchboard put up by the Newcastle company, in the manner indicated, which was apparently safe, but did not conform with the regulations. Had the person putting it up to write to the Home Office and get sanction, or had he to wait until some criminal proceedings were taken? If he had to write to the Home Office and get sanction, was the Home Office going to have a number of people to deal with these matters? If the occupier did not write to the Home Office, he apparently would work the switchboard not complying with the regulations at his own peril. There were two cases in which an occupier might be prosecuted by the Home Office. First, if an accident happened, and again if the switchboard did not comply with the regulations. What would the position of the occupier be if an accident occurred in a case, first, where the occupier had sent to the Home Office, and came under Exemption (*e*), and, secondly, in the case where the occupier might come under Exemption (*e*), but had not referred to the Home Office for sanction?

Mr. GRAY said that the Home Office had discussed the whole of this question, and he would like to state what the practice would be. A factory inspector visited all works periodically, and the practice in this case would be that if the inspector thought the switchboard did not comply with the rules, he would tell the occupier that it must. The occupier would appeal to the electrical inspector, and if it was possible, the electrical inspector would give a certificate that the works came within the Exemption. But supposing it was impossible for the electrical inspector to give a certificate to this effect, notice would be given to the occupier to make such alterations as were necessary to bring it within the exemption, and if this were not complied with, whether the prosecution was as the result of an accident, or by reason of non-compliance, the person being prosecuted would have every opportunity at the criminal proceedings of satisfying the magistrate that whereas he did not, as a matter of fact, comply with Regulation 17, he had taken such precautions as, in his opinion, created a condition of things less dangerous than if he had complied with the regulation.

Lord ROBERT CECIL said he was not satisfied with an explanation of what the practice would be, but preferred to know exactly the legal position of an inspector under the circumstances in question.

Mr. SWINBURNE suggested that the matter might be left over for the present. He wanted to know what the law was, and what was the exact position with regard to responsibility of the man who put up a switchboard in the manner mentioned.

Lord ROBERT CECIL proposed that a statement with regard to the law on this point should be made so that the objectors and the Home Office could agree. He complained that the rules gave very great powers to the Home Office, and the objectors were asked to believe that the practice of the Home Office would not be so stringent as their regulations.

Mr. GUTTRIDGE, on behalf of the London County Council, said that the question of civil action in relation to accidents in works in consequence of the existence of Regulation 17 must also be taken into account.

Mr. W. H. PATCHELL was then called in support of Regulation 17. He said he had been a member of the Committee

Digitized by Google

appointed by the Home Office in 1903 to consider the application of electricity in mines, and the same difficulty with regard to fixing definite spaces for switchboards had been encountered. Definite distances had, however, been set down, and in practice he was not aware that it had given very much trouble. They certainly caused him some anxiety at the first in a case where the switchboard was absolutely enclosed, and he did not know what construction to place upon the rule in regard to how the distance was to be measured, namely, from the live metal to the side of the passageway or from the door in front of the compartment. It was decided, however, that the measurement should be taken from the live metal inside. Generally speaking, he thought it would be a very great assistance to have definite dimensions in the regulation, although he recognised the difficulty with regard to existing works. He thought the owners of such works could fall back upon the exemption.

Cross-examined by Lord ROBERT CECIL, who asked for the words "as far as reasonably practicable" to be made applicable to all the regulations, witness expressed the opinion that the exemptions would have the same effect. He agreed that the Coal Mines Regulations left all existing apparatus untouched until an inspector directed a change to be made, and in these circumstances the owner was given the right to appeal to arbitration. This regulation had been dratted in view of the fact that there were at that time very few installations in mines. He could not see that this was an unreasonable provision in respect of central station switchboards.

Mr. VESEY KNOX reminded Mr. Patchell that under the Coal Mines Regulations an exemption from the Secretary of State was a bar to prosecution. Mr. Patchell also agreed that the mining rules were also drawn up mainly from the point of view that the persons in charge of electrical machinery in mines had not had very great experience, a condition which did not apply to ordinary central stations.

In reply to Mr. PRITCHARD, on behalf of the municipalities, Mr. Patchell agreed that there was no exception in the Mines Regulations as to bare conductors on both sides of the switchboard, but the conditions were somewhat different in the mine. He thought the dimensions in the regulations were reasonable for new work. A suggested alteration to the definition of "passage way," namely, "Way intended for passage of persons engaged in the operation or control of the switchboards," Mr. Patchell saw no objection to.

Mr. ALEXANDER SIEMENS, for the Institution of Electrical Engineers, suggested an alteration in the definition of "passage way," by adding, "unless the same is made inaccessible by a wall or a door which can only be opened when the board is dead, except by an authorised person."

Mr. COZENS-HARDY suggested an addition to this definition which would make it not applicable to low or medium pressure boards. Mr. Patchell disagreed with this.

Mr. W. B. WOODHOUSE asked if it were not possible that, in trying to follow these rules, the design of switchgear might be made more dangerous. He put a specific case of a certain kind of switchgear, in which all live parts behind a panel, which was two or three feet wide, were made live through fuses at the top about six feet high, there being live metal behind and a handle in front. This was in a mine, and the inspector under the Coal Mines Regulations insisted that either the panel, which was three feet wide, should be moved a distance to allow a three feet passage way, or that each end of the panel should be protected by a door which could be opened on the inside without a key. Very considerable expense was thus incurred without additional safeguard, and the result was that all live metal was removed to the front of the board, the fuses were placed within 2 ft. of the ground, and the operator had to operate a switch with live metal within a few inches of his hand, not protected by a slate panel as before.

In answer to further questions, Mr. Patchell agreed that so far as he was concerned, a memorandum from the Home Office indicating what should be done would be sufficient, but he did not think it safe to rely upon this method for all cases.

Mr. H. M. SAYERS, for the Tramways and Light Railways Association, pointed out that these rules would, when they came into operation, be applicable to coal mines, and would presumably supersede the Coal Mine Regulations now in force. Asked as to whether he thought this would be an advance, Mr. Patchell said he did not know.

Mr. J. F. C. SNELL, called on behalf of the Home Office, said he entirely agreed with Rule 17. While recognising the difficulty of fixing definite figures, he considered a high standard of work was set by these regulations. He had come across several low-pressure boards where at the back there were resistance frames, or cables on the floor, all of which had formed obstructions which were undesirable, and which were not indicative of good design. With extra high pressure boards, it was not unusual to find transformers placed in a position where they formed an obstruction to the passage way. He entirely supported Mr. Ram's conclusion that the passage way should be clear and unobstructed. If any works could not be made to comply with the regulations, they should be reconstructed, but he thought such cases would be very few. In two cases, recently, of electrical design with which he was concerned he had adopted very nearly these dimensions before the regulation was drafted.

In answer to Lord ROBERT CECIL, Mr. Snell stated that one of these cases was a high-pressure board, in which, although the bus-bars and all live parts were contained in cubicles and further protected by iron doors, he allowed 4 ft. 6 in. between the wall and the iron plate forming the cover of the cubicle. So far as he was concerned, he saw no objection to the introduction into the regulations of the Coal Mines regulation which stipulates that existing apparatus shall be left unless an inspector otherwise directs.

In answer to Mr. Vesey Knox, Mr. Snell stated that he did not think any of the sub-stations designed by himself during the past three years would not comply with the dimensions in the regulations.

Mr. A. SIEMENS, on behalf of the Institution of Electrical Engineers, suggested an alteration in the wording of Regulation 17, to provide for switchboards which are fitted with doors or other devices which cannot be opened whilst the switchboard is live, except by an authorised person. Mr. Snell thought Exemption *e* provided for such cases, and if they were to put every specific case into the regulations, then it would make them too long and burdensome.

This closed the case for the Home Office in regard to Regulation 17.

It may be pointed out that the comparatively small amount of cross-examination is due to an intimation from the Commissioner that the fact of an objector not having cross-examined, will not tell against him, as the cross-examination that has taken place will be considered in favour of every objector who had lodged objections. This course has been adopted owing to the large number of similar points covered by different objectors.

The case for the opposition to Regulation 17 was opened by Lord Robert Cecil, on behalf of the London Electric Lighting Cos.

Mr. C. P. SPARKS, Chief Engineer to the County of London Electric Supply Co., said that his principal objection to Regulation 17 was that its application would necessitate expensive alterations from the low-pressure point of view. He was quite certain that it would make structural alterations necessary, which it would be physically impossible to comply with. With high pressure and extra high pressure the difficulties might not be so great. As an instance of his objections, Mr. Sparks produced a section of the sub-station belonging to the Richmond (Surrey) Electric Light & Power Co., which supplies direct current upon the three-wire system at 110 and 220 volts, and power at 220 and 440 volts. The distance from the back of the switchboard to the wall was 3 ft., but taking into consideration the bus-bars the clear space was 2 ft. 4½ in., and between the bus-bars and the brick buttress there was only 2 ft. clear space. It was physically impossible to increase these measurements. There had been no accident on this board, and in his opinion it involved no danger. The station had been in existence for 17 or 18 years; the width of the engine-room was 22 ft. 9 in., and the distance from the front of the board to the pedestal of the machinery was 4 ft.; thus it was impossible to bring the board further out, and to set it further back would involve the reconstruction of the buildings, as the boiler-house adjoined. They had no powers to acquire land compulsorily, so that if these regulations were enforced upon them, they would have to do so by agreement with owners of the adjoining property, in which case a very prohibitive price would have to be paid. He did not agree that the occupier was sufficiently protected by the exemption, and he did not think he personally could bring his stations within Exemption (*e*). The ordinary factory inspector took a very narrow view of things, and naturally would not take the responsibility of giving the owner the benefit of the exemption. He was of opinion that the Coal Mines Regulation, to the effect that the existing precautions might be continued until an inspector directs otherwise, ought to be put into these regulations. His opinion was that a coal mine inspector was a very much more specialised individual and of a far higher calibre than an ordinary factory inspector, and seeing that an appeal was allowed in mines, he thought the case for an appeal in the case of the present regulations was much stronger.

Cross-examined by Mr. GRAY, he stated that he saw little to object to with regard to the dimensions in the regulations in their application to new work. Concerning existing work, he could not accept the assumption that the regulations would be administered reasonably from his point of view, as he could not conceive a sufficiently broad-minded inspector to take the responsibility of giving him the benefit of the exemption. He believed it would be practically impossible to convince an inspector that a station could be made equally safe even if it did not comply with the regulations. He was quite convinced that if the regulation came into force the board at Richmond would have to be reconstructed. The only way in which the board could be made to comply with the regulation was to have a remote control switchboard, for medium pressures, which would be too expensive.

Mr. C. H. MERZ, for the Newcastle Electric Supply Co. and the two Durham power companies, said that by enabling electrical engineers to design switchboards upon certain lines, it was possible to supply electricity economically at very low prices, but if restrictions were to be placed upon them in relation to their design, the cost of these boards would be increased and all the advantages of cheap electricity would disappear. The companies which he represented supplied about 130,000 to 150,000 h.p. of motors, and the capacity of their ninety-six sub-stations

Digitized by Google

was about 100,000 kw. New sub-stations were being erected at the rate of 30 or 40 a year, and he regarded the setting up of dimensions, as proposed, a backward step. If Mr. Ram meant that a space of 4 ft. from the wall of a cubicle on a switchboard with isolating switches and a door would comply with the regulations he thought that would get rid of many objections, but it was not in the regulation. The Home Office had suggested that nobody but themselves cared for the safety of the workmen. As a matter of fact, all designs were looked at from the point of view of safety to workmen, although more or less linked up with this was the question of security of supply. If the Home Office wanted the greatest safety, then they had specified the wrong thing in these regulations. If there was one thing necessary in extra-high tension work, it was that each panel should be entirely separate. This was far more important than that any passage should be 2 or 4 ft. wide. Personally he would specify absolute clear sub-division of panels, and clear means of indicating which panel a workman was at work on. The design of sub-stations was developing and improving, and the fixing of specific dimensions was the wrong way for getting safety. Mr. Ram had expressed a preference for iron sheets under isolating switches. The Newcastle Co. had, as a matter of fact, abandoned this method because they considered it was more a source of danger than the reverse. Another important point not mentioned in the regulations was the space between poles. These things were much better discussed whilst looking at the actual boards, and he would therefore like the Commissioner, if it were possible, to pay a visit to some of the Newcastle sub-stations. A special objection related to the electrochemical industry, namely, whether these regulations were necessary below 250 volts. The Castner Kellner Alkali Co., which took current from the Newcastle Co., used a great many bare wires which they were afraid might be claimed as part of the switchboard, and in that case the limit of low pressure was too high to exclude them from the regulations. He thought it would be only fair to say that electrochemical works below 250 or 500 volts should be excluded.

In cross-examination, Mr. Gray pointed out that Mr. Merz, on the point of separate panels, had overlooked Regulation 18 (*d*), which provided for these. Mr. Merz replied that this regulation did not go far enough, which emphasised his point as to the objection to regulations upon specific details. To deal properly with this point alone, would require a four-page specification. The only reason he could give for wishing to have the dimensions in was that it made the regulations intelligible to the inspector. He agreed that 3 ft. was a safe width for a passage-way, if the switchboard was properly designed in other respects.

Mr. W. W. LACKIE, Chief Electrical Engineer to the Glasgow Corporation, gave particulars of one of his boards, in which the total space from the back of the switchboard to the machines was only 4 ft. 6 in., whereas to carry out the regulations there should be 17 ft. under the conditions prevailing. The present arrangements had been in existence for some years, and had been perfectly safe. He had made an estimate of what it would cost to absolutely comply with the regulations, and it would involve the abandonment of two sub-stations containing 9,000 kw. of plant at an expenditure of £120,000. He agreed with the previous evidence that it was unnecessary to define dimensions.

FRIDAY, MARCH 6TH. FOURTH DAY.

Mr. LACKIE handed in further photographs of the Waterloo Street and St. Andrew's Cross sub-stations, the switchboard conditions in both of which he said would not comply with Regulation 17.

In cross-examination, Mr. Lackie stated that the floors of the switchboard galleries were made of glass, and there were a number of holes about one foot square through which the 250-volt bus-bars passed. He regarded these conditions as absolutely safe, although a man would get a shock if he put his foot on the metal work of the board, and touched one of the bus-bars at the same time. He thought the boards were safer than they would be if constructed under Regulation 17.

Mr. GRAY: Then you would come within the exemption?—But I do not come within the rule.

Discussion took place between Counsel and the witness as to what alterations could be made in the event of an inspector certifying that these boards did not comply with the regulation. Mr. Gray suggested the arrangement of the bus-bars in the same plane along the passage instead of across it. Mr. Lackie objected to this on the ground that where the bus-bars came under the board, they would have to be crossed, which would introduce an element of danger in cleaning, quite apart from the question of expense. Objection was also taken to Mr. Gray's suggestion that the bus-bars and other live metal could be covered, on the ground that this would interfere with efficient cleaning. Of course, said Mr. Lackie, if the bus-bars were covered with insulation, they might be made safe in that way.

The question was then discussed of making rheostat contacts safe by protection. Mr. Lackie argued that any form of covering would hide the contacts from the operator, thus preventing him from knowing when they were working properly.

So far as getting over the difficulty of bare conductors was concerned, of course, a glass plate could be placed over the rheostat. Various suggestions by Mr. Gray as to guarding the machinery in the sub-stations, which are very close to the switchboards, were agreed to by Mr. Lackie in so far as they were possible, but he would not accept the suggestion that the degree of security afforded by these methods would be commensurate with the expense involved. A suggestion by Mr. Gray that the St. Andrew's Cross sub-station switchboard could be raised, and so made to comply with the regulation, was met with the answer that this would necessitate an alteration in the position of the travelling crane. In many cases Mr. Lackie agreed that, whilst the covering up of the bare conductors might make things safer from the point of view of workmen, there was a strong possibility of introducing extra risks of fire.

Mr. SYDNEY MORSE here suggested that Rule 55 of the Coal Mines Regulations should be adopted by the Home Office; such an action would, he said, considerably shorten things from his point of view, and possibly from others. This rule read as follows:—

"Notwithstanding anything contained in these rules, any electrical plant or apparatus installed or in use before the coming into force of these rules may be continued in use unless an inspector shall otherwise direct, or subject to any conditions affecting safety that he may prescribe.

"In case any difference of opinion shall arise between an inspector and an owner under this rule, the same shall be settled as provided in Section 42 of the Coal Mines Regulation Act, 1887."

Mr. SWINBURNE said that it appeared the objectors were running two cases against Rule 17. First, that there should be no dimensions, and, secondly, that it did not include an exemption for existing work. He suggested that some addition might be submitted by the objectors, which would definitely lay down when an existing station was complying with the regulation without having recourse to the inspector.

Mr. A. A. CAMPBELL SWINTON, by agreement, gave evidence at this stage, in the interests of 42 stations supplying electrical energy under Provisional Orders, including the whole of the Edmundsons' group. Regulation 17, he said, affected small concerns much more than larger ones, on account of the very unsatisfactory financial position of such undertakings. The question of safety, he said, was a comparative one, and personally he preferred to have bare live metal about a station, with strict instructions to the workmen as to the nature of the place in which they were working. He had a 10,000-volt battery in his own office, and no precautions were taken in the way suggested by these rules. In reply to Mr. Gray, Mr. Swinton said he had no objection to the rules for new work.

Mr. H. TALBOT, President of the Incorporated Municipal Electrical Association, and Chief Electrical Engineer to the Nottingham Corporation, supported the previous evidence as to deleting the dimensions from Rule 17, and asked for a complete exemption for existing work. He preferred to have the passage-ways about a switchboard as narrow as possible, so that they would not be used by the workmen except for the purposes of their work. When these passage-ways were made too wide, the workmen frequently made use of them as a short cut for leaving their work at night, and so on.

Mr. GUTTRIDGE, on behalf of the London County Council, expressed his intention of not calling evidence, but of relying on the view already expressed by other witnesses.

Mr. W. B. WOODHOUSE, for the Yorkshire Electric Power Co., did not call evidence, but drew attention to a type of switchboard not already mentioned, namely, remote control extra high tension switchgear. On these boards they had direct current, and two alternating-current systems in close conjunction with each other. The point that he wanted to make was that the standard voltage for alternating-current instruments transformed from extra high tension would bring that type of board under Section 17. It would be difficult to make such a board conform with Rule 14 (c) or 18 (d). Further, some types of remote board were almost horizontal, and it was difficult to see how this type of board was going to be treated under Section 17.

Mr. RAM was then cross-examined with regard to Rule 12.

In reply to Mr. Vesey Knox, he stated that he was informed that no-voltage releases for alternating-current motors were on the market, and that several were in use.

Mr. VESEY KNOX stated he was instructed that there was no standardised article to be obtained commercially which would comply with the requirements of this rule in the case of a single-phase motor.

In the course of further questions, Mr. Vesey Knox put the case of a three-motor crane used in dock work, with a competent man constantly in charge. Was it not sufficient if this man had means ready at hand to turn off the current in case of need? Mr. Ram thought the man might forget to do so.

Asked as to accidents which had led him to draft this rule, Mr. Ram mentioned the case of a printing machine motor in which the current failed, and the machine stopped. Whilst the electrician on the premises was putting in new fuses, the machine operator thought he would take the opportunity of getting into the machine to oil the bearings, or something of that sort. He had forgotten to turn off his switch, and the man replacing the fuses, which were in another room, gave no warning that he had done so. The result was that the motor

Digitized by Google

started, and the operator was caught in the printing machine and killed. He had formed no estimate as to what the cost of fitting such a device on motors would be, but it might vary, according to the size of the motor, from 10s. to £10. With continuous-current machines it would not add 10s. to the cost of the starting switch. He admitted that he had never seen a no-voltage release for alternating currents, but he had been invited to see several in operation.

Mr. VESEY KNOX pointed out that the rule would make failure to use this piece of apparatus, which Mr. Ram had never seen, a criminal offence.

Further cross-examination elicited the information that the regulation did not necessarily mean that every motor should have such a release. One might do for several motors, and certainly, in the case of a three-motor crane, one would do. In fact, he saw no reason, according to circumstances, why one release should not do for all the motors in one room.

As a further justification for enforcing this rule, Mr. Ram referred to the Institution of Electrical Engineers' Wiring Rules 91*f* and 91*h*, of the 1907 edition, which require automatic releases on both alternating- and continuous-current motors.

Mr. VESEY KNOX pointed out that this was not a compulsory rule, but was merely a suggestion for guidance, and there was a permanent committee which made alterations from time to time. The Home Office Regulation was one which could not be altered except under a procedure involving an inquiry if there was opposition.

Mr. SYDNEY MORSE raised the question as to whether the size of the motor should be one-third horse-power as the minimum. He thought this was much too low, but was prepared to leave this to the Commissioner.

Mr. ALEXANDER SIEMENS asked Mr. Ram if he could not accept the suggestion of the Institution of Electrical Engineers, namely, to add "unless the motor is automatically prevented from re-starting."

Mr. RAM thought it possible that this might be accepted.

Mr. SIEMENS, in the course of a few further questions, indicated that in his opinion to put a no-voltage release into the circuit was the same as putting in another fuse, and taking Mr. Ram's instance of the printing machine fatality, he argued that if the man who had put in the fuses had replaced the automatic cut-out, also without warning, the accident would have happened all the same.

Mr. COZENS-HARDY pointed out that there was a very distinct objection to having a no-voltage release on a lift.

Mr. RAM thought a sufficient case could be made out in regard to lifts to secure an exemption. A suggestion by Mr. Cozens-Hardy that the automatic no-voltage release might be on the distribution board ten minutes away from the lift-man, was not assented to.

Mr. RAM gave, as an example of why this rule would be useful for cranes, the case of a man operating an overhead travelling crane. The current came off, and not knowing what was the matter, he got out of his cage and began to crawl along the gangway to get down to ascertain the cause of the stoppage. In the meantime the current came on again, and having forgotten to leave his controller in the "off" position, the crane started, caught him up, and crushed him. Had there been a no-voltage release, that would not have happened.

As an instance of the saving of time which the use of no-voltage releases would effect, Mr. Ram mentioned that one power company in this country, which did occasionally have an interruption of supply, had made it a rule that their consumers, in the case of interruptions, should not expect the supply to be resumed in less than eight minutes, as it took that time to go round and pull off the switches. If automatic switches were used a considerable saving in time, and consequently in money, would be made.

A series of questions were put by Mr. Cozens-Hardy with regard to what might happen if Mr. Ram's suggestion that one release would do, in the case of small factories, for the whole of the installation were adopted. He contended that the danger would be as great, if not greater, than if there was no automatic release at all. The point he wished to make was that Mr. Ram's argument that the expenses would not be great did not hold, for the reason that in his view, to carry out the regulation an automatic release must be put at every switch, otherwise the regulation was useless. Mr. Ram said a warning would have to be given when the no-voltage releases were replaced.

Mr. W. B. WOODHOUSE suggested that the extra cost of motors, in consequence of this regulation, would tend to prevent the use of electricity. In other words, the keen competition between various forms of power would turn the balance against electricity by the extra capital cost of the motors. Taking the instance mentioned by Mr. Ram of the printing machine, he argued that this was really a case for fencing the machinery to prevent the man from getting into it. Mr. Ram refused to admit this contention for the reason that, in his view, the no-voltage release would have acted, and the operator would have been given warning when the current was on again. That was the object of the regulation.

Mr. WOODHOUSE next took the case of textile mills with a steam engine driving long lines of shafting fitted with fast and loose pulleys for operating the various machines. He said that no regulation had been made to prevent injury to the work-people by the sudden stopping of the steam engine, and it frequently happened that the engine stopped and was started again without any warning. The only rule was that whenever the main shaft stopped, the operators were to put their belts on to the loose pulley. From this he argued there was similarly no need for the operator of an electric motor to be further protected in a case of stoppage of current, than being instructed to put his switch in the "off" position. In fact, he said, this was a machinery trouble, and not an electrical one. Continuing, Mr. Woodhouse stated that in the case of a shunt motor, these devices had been fitted as a precaution to the motor itself, not to the workmen, and therefore to say that because they were fitted to continuous current motors they should be fitted to all motors, was not a good argument.

As a result of further discussion, Mr. Ram said that in the case of the cranes which he had mentioned, he believed that a system had now been adopted by which the man could not leave the cage of the crane except by opening a door, and this door opened the switch. Such a device, he said, would get the benefit of the exemption.

Mr. WOODHOUSE, as a further illustration of the hardship of enforcing this regulation in all cases, mentioned a pump filling a tank in which a float at a certain level of the water operated a switch which shut off the motor. He saw no reason whatever for putting upon them expense of this no-voltage release in such instances.

Mr. A. M. SILLAR asked that the rule should not be made to comply to such classes of machinery as capstans, cranes, &c. In the case of a capstan, no possible harm could be done, as the moment the operator took his foot off the treadle, the motor stopped. So far as cranes were concerned, he thought they were much more safe without no-voltage releases.

Mr. RAM: Then if you satisfy the inspector on this point, you come under the exemption?

Mr. SILLAR: Yes, but who is to determine this point?

In re-examination, Mr. Ram proposed that the rule should be altered to read "either switch off the motor, or stop the machinery." This alteration was made to prevent the interpretation of the rule that in the case of machinery which had large momentum and would continue to revolve after the current was shut off, the owners should not provide a brake.

Mr. VESEY KNOX, reverting to the point that the rule need not necessarily mean that one release should be fitted to each motor, said that the view of his advisers was that there should be either one to each motor or none at all, and that in the former event the cost would be prohibitive.

Mr. W. H. PATCHELL was then called with regard to the use of no-voltage releases for alternating current. He had used them on 440 volts and 2,000 volts in each case successfully, but not for very small motors. The expense was certainly an item, and a bar to their use with regard to small motors. This, therefore, would be met by grouping the motors, which he understood the Home Office would accept; otherwise the apparatus would cost as much as, if not more than, the motor which it was to control. Such a piece of apparatus was quite commercial, and he had tried several kinds from various makers. There was a German one sold in England by the Union Electric Co., which had been very successful, although others made in England had not been so satisfactory.

Cross-examined by Mr. Vesey Knox on the question of cost, Mr. Patchell said he could not state definitely because he had always had them combined with a maximum switch, but he thought that £6 or £7 would be substantially correct for large motors, but it was not commercial to supply them with small motors. Asked as to an instance in which a no-voltage release would have prevented danger, Mr. Patchell said he could call to mind no others than those mentioned by Mr. Ram.

Mr. WOODHOUSE pointed out that no provision for the use of these apparatus in mines had been made in the Coal Mines Regulations, and to this Mr. Patchell assented, but he said the fact that such a rule was necessary was proved by a case recently, in which a man had been caught in a coal-cutter through the current coming on suddenly.

Evidence was then heard against Regulation 12.

Mr. C. H. MERZ said he had 3,000 or 4,000 h.p. of motors connected to his mains, not one of which was fitted with the automatic release. He did not know of one in use anywhere in the world; he had never seen such an article, although he had been through America, Germany, and factories in many other places. Some ingenious person might have invented one, but the thing did not exist as a commercial article. The curse of the electrical industry was that so many fakes could be made. The industry had gone on very well in the past without these things, and seeing that the tendency now was towards fewer interruptions of supply than formerly, he failed to see the need for enforcing such a regulation now. It was quite clear that in such a factory as, for instance, a shipyard or marine engine works the grouping of motors and fitting of automatic releases would be absurd. There were in such factories sometimes mere momentary interruptions due to the local man in the switch-room manipulating his switches. With automatic releases fitted, there would be interruptions from this cause with the same effect as if there was an interruption of supply at the power

Digitized by Google

station. Further, according to the regulations these releases would have to be fitted to motor-generators, which was very undesirable. If the appliance was to be fitted at all, it should be fitted to every motor, but this would be a serious matter financially, and would only introduce another possible source of breakdown. The feature of the alternating-current motor was that it was a machine, and not a piece of electrical apparatus, and that was why it was being so largely adopted. The great advantage of power supply was in the use of induction motors without slip rings.

Mr. Merz then made a few comments upon Regulation 4. Even as redrafted, he said, this might apply to isolating links which would be absolutely useless for breaking the circuit. If they omitted the words "intended to be used for breaking the circuit," this would meet his point.

Mr. Gray pointed out that it was the intention of the rule not to include isolating links.

Mr. Merz, continuing, thought that the rule should not apply to apparatus below 250 volts, and that the power should be limited to 100 h.p., or something of that sort. In a great many cases, switches upon switchboards were practically nothing more than isolating links, and they were quite satisfactory for small powers.

With regard to Rule 7, he thought this was not practicable. Having regard to the Board of Trade definition of the word "circuit," one lamp would mean a circuit. He asked that the regulation should end at the word "apparatus." For instance, winches in a shipbuilding yard would be compelled to have a separate switch for each circuit.

With regard to Regulation 8, the same argument applied. It might be right in small shops, because 750 watts was a very small power, but it was really not quite practicable in big shipyards.

With regard to Regulation 12, he objected to the second paragraph, and regarded it as almost unmeaning. Plugs were usually used upon the circuits in shipyards and the limit was too small. Great care was taken with disconnectors and plugs in shipyards on the Tyne, and there had been no trouble in using the switches.

Cross-examined by Mr. Gray with regard to Rule 12, Mr. Merz stated that the desirable thing for a man to do when operating a motor and the current failed was to put his switch off. So far as the manufacturing centres on the Tyne were concerned, it was not a very common thing for a man to walk into his machine when the power went off the motor. For instance, a man would not walk into the gear of a punching machine. He thought it was just as essential to have automatic means for putting the belts of individual machines on to the loose pulley if the gas engine or steam engine stopped, as it was to have an automatic switch on a motor. In the case of very complicated machinery, it might be necessary to have a no-voltage release, but as these only represented about 5 per cent. of the machines driven by motors, he thought it unfair to make rules for 5 per cent., and to which the other 95 per cent. not concerned had to conform. He thought that 5 per cent. was an excessive allowance as the number of alternating-current motors in use which ought to have such devices.

Mr. Gray: But up to what size do you allow induction motors to be set on to the mains without special starting devices?—We do not make any special regulations; we do not believe in hindering the use of electricity by regulations, and we therefore make none. What starting devices are used, are provided by the consumers themselves to prevent excessive rushes of current.

In reply to further questions, Mr. Merz stated that to have a no-voltage release on a long circuit as well as fuses, would be quite wrong practice; if they were going to have regulations that were stupid, let them be as little stupid as possible.

Mr. Gray: All this refers to your own works in which supply is very constant?—Yes.

But in other factories there are more frequent interruptions, for instance, where there is a private generating plant. Do not you think that in those cases automatic releases should be used?—Ninety-nine per cent. of the users of these motors have been using them for eight years in England and fifteen years in America, and in a sense you are putting upon us the onus to prove that they are not dangerous. I consider the rule is dishonest in its drafting for that reason.

Mr. Gray: You have been using some strong expressions, Mr. Merz; you first say that these rules are stupid, and then dishonest. Do you suggest that any of these regulations are put forward in any but a *bonâ-fide* manner?

Mr. Merz: I do not wish to use too strong expressions, but I think you know what I mean.

Mr. Gray: I am bound to say I do not. With all respect, you ought not to use such expressions with regard to any of these regulations.

Mr. Swinburne: Supposing, Mr. Merz, you have a motor of 50 or 100 h.p., and you have a choking coil in series for starting as usual. Supposing there is a stoppage due to the power station, when you start up again do you give them full volts at full frequency right off, or do you go up gradually from the low frequency to the high?

Mr. Merz: I should say that they would switch straight on as the only practical thing to do, and in the case of a large motor, unless it were driving a pump, probably the fuse would go, so that you really have a device equivalent to a no-voltage release. The bigger motors generally start with the load off.

The inquiry was then adjourned until Monday, March 15th.

THE ENGELBERG-LUCERNE 25,000-VOLT OVERHEAD TRANSMISSION

In a previous issue (*see* Electrical Engineering, Vol. II., p. 439) we gave a full description of the hydraulic works and power station recently established between Obermatt and Engelberg by the Lucerne-Engelberg Electricity Works Co., for the supply of power and lighting to Lucerne and the surrounding district. The following is a description of the high-tension transmission lines and sub-stations belonging to this company.

The main overhead line, which consists of nine copper conductors supported on a single line of steel lattice poles, runs from the power station near Obermatt to a sub-station at Steghof in Lucerne, and is 16·7 miles long. The nine conductors are utilised as follows: Three form a single three-phase circuit from the power house to Steghof for the power supply in Lucerne; another three form a three-phase circuit from the power house to the sub-station at Stansstad for the lighting and power supply in the Nid- and Obwalden districts, but are continued on to Steghof as a reserve circuit; two of the remaining three conductors are used for the single-phase lighting supply in Lucerne, and the remaining conductor is a reserve, and can be used in any circuit. The line is intercepted at three points—namely, at Wolfenschiessen, Stansstad, and Hergiswyl—for the double purpose of taking off power for the supply of the surrounding districts and for interposing section switches. At these three points all nine conductors are carried into massive stone towers which contain the section switchgear and the transformers for the local supply. From the station at Stansstad a branch three-phase line supplies the sub-station in the town of Stans, and another line which goes out from the station at Steghof supplies the sub-station at Kriens.

The main line crosses the Stansstad-Engelberg railway four times, and the Brünig railway four times. The general character of the overhead construction and the steel lattice poles themselves can be seen from Fig. 1, which shows a portion of the line in the neighbourhood of Steghof. The lattice poles here shown are embedded in the concrete foundations, and are spaced about 180 ft. apart. The cross-arms, which are of steel, support two vertical beams of impregnated oak, to which are fixed the iron pins of the insulators. The conductors are 40 in. apart. There are 469 lattice poles between Obermatt and Lucerne. The weight of each pole is about 1,750 lb., and the cost about £11. The cost of erecting the poles, inclusive of the material for the foundations, works out at about £12 per pole; this figure includes the additional expenditure due to the special construction along the base of the Lopperberg. The poles are earthed in the following manner: Every pole is electrically connected with a copper wire

Digitized by Google

of 0·2 in. diameter which runs the whole length of the line, and every tenth pole is electrically connected to a copper plate, with a total surface of 10 square feet, which is buried at the foot of the pole. The telephone wires connecting the power station at Obermatt with the various sub-stations are also carried on these steel poles, and in order to avoid any disturbances, the two wires, which are of bronze and 0·12 in. in diameter, are crossed every 300 yards. These telephone wires can also be put in connection with the public telephone system, although it does not seem that any special precautions are taken to prevent accidental contact between the high-tension wires and the telephone wires.

Between the Stansstad sub-station and that at Hergiswyl the line runs along the side of the road at the edge of the Lake of Lucerne. On the one side of the road the rocky slope of the Lopperberg rises steeply, and on the other side is the edge of the lake, which rapidly deepens. The special construction shown in Fig. 2 was therefore resorted to. The lattice pole is fixed to a steel bracket, the end of which is embedded in a massive block of concrete, as shown in the diagram. The wall built over this block is to protect the pole from the boulders which occasionally roll down the side of the Lopperberg. The poles would have been placed at the edge of the road, but there was already a line of telegraph and telephone wires which could not be moved. In order to reduce the number of poles along this portion of the route, the average span was doubled, *i.e.*, 360 instead of 180 ft.

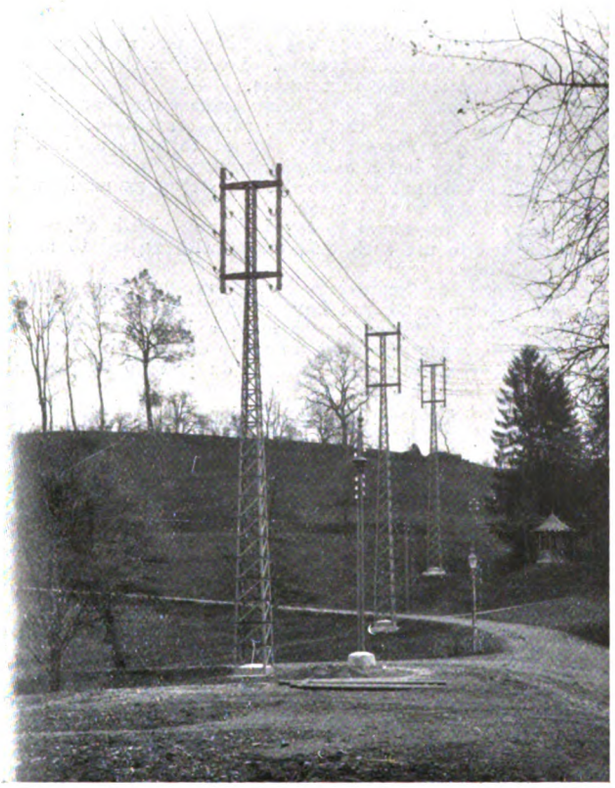

Fig. 1.—The Overhead Line near Steghof.

The transformer sub-stations at Wolfenschiessen, Stansstad, and Hergiswyl contain each one oil-cooled three-phase transformer with a capacity of 30 kw. These transformers transform down from the line pressure of 25,000 volts to a pressure of 350 volts. The secondaries are star connected, and the neutral point is earthed. Lighting is done between one phase and the neutral conductor, *i.e.*, about 200 volts across the lamps. The transformers are well protected against lightning, &c., and all the high-tension switchgear is arranged, as was described in the case of the switchgear in the power station, in fireproof cells.

The lightning arresters, which are of the horn type, are connected to earth through water resistances. The water is mixed with a little glycerine to prevent it from freezing in winter. The sub-station at Stansstad is larger than the other two, and contains, besides the small three-phase transformer for the local supply at 350 volts, two 250-kva. transformers which transform down from 25,000 volts to 5,000 volts. These last supply power, over the three-conductor line already mentioned, to the town of Stans. The town of Kerns also receives a supply at this pressure.

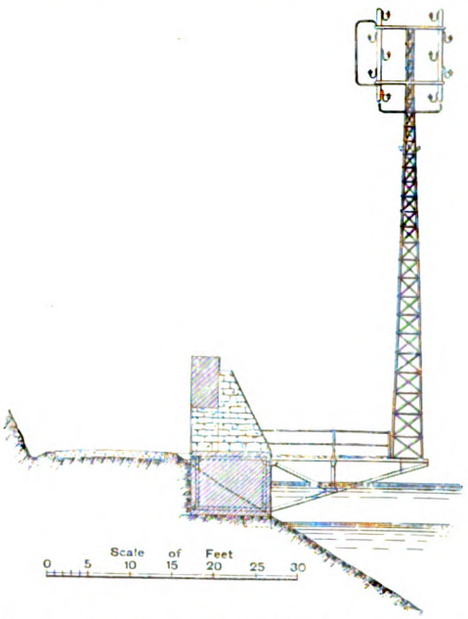

Fig. 2.—Lattice Poles and Bracket Construction along the edge of the Lake.

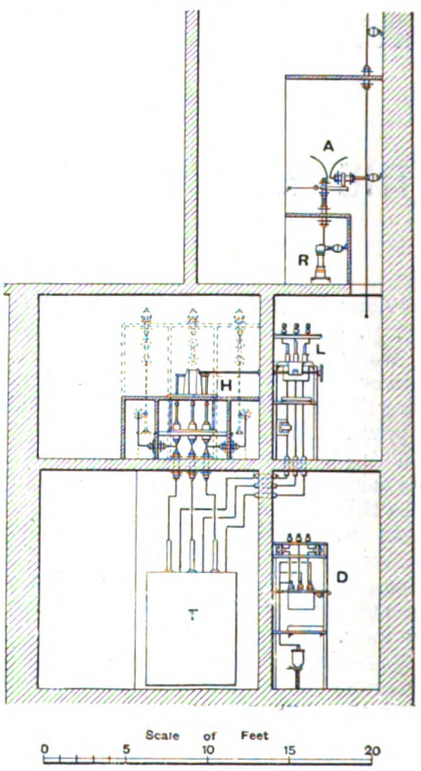

Fig. 3.—Section through the Transformer Sub-station at Kriens.

Digitized by Google

The sub-station at Steghof for Lucerne is an extension of the old power station for the Lucerne tramways. This station contains the three-phase transformer plant for the power supply, the single-phase transformer plant for the lighting supply, and the motor-generator plant for the tramway supply. This sub-station contains, as do all the others, lightning arresters and other protective devices, also automatic oil-switches and other necessary switchgear. The transformers and switchgear are arranged in a similar manner to that at the power station at Obermatt. The pressure is transformed down from 25,000 volts to 2,650 volts, which is the pressure of the outgoing lighting and power supply cables. The lighting transformer plant consists of three 700-kva. single-phase units, exactly the same, as regards construction and method of cooling, as those described in the previous article (*see* Electrical Engineering, Vol. II., p. 445). The power transformer plant consists of three groups of three 300-kva. units arranged in mesh connection. The frequency of the supply is 50 cycles per second.

Room is provided for three motor-generator sets for the tramway supply, but only two are installed at present. The asynchronous three-phase motors are rated at 340 kw., 2,650 volts, 490 r.p.m., and are direct-coupled to continuous-current generators rated at 300 kw., 575 volts. A battery of accumulators situated in the old power station is used in parallel with these motor-generators.

As has been already mentioned, a high-pressure line, consisting of three conductors, connects the sub-station at Steghof with a sub-station at Kriens. This station

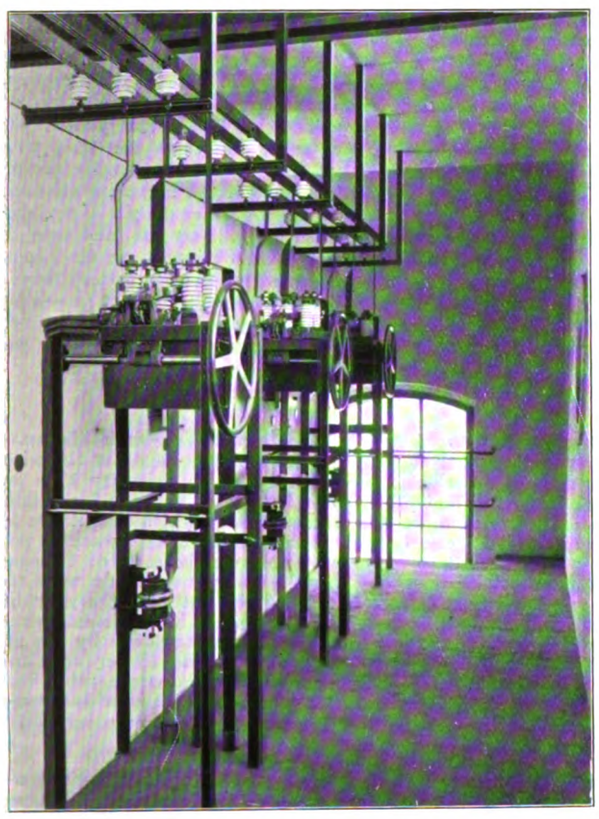

Fig. 4.—Low-tension Transformer Switchgear in Kriens Sub-station.

contains three oil-cooled three-phase transformers, rated at 450 kva. each, and transforming down from 25,000 volts to 500 volts. This sub-station is chiefly for the supply of a large silk factory, which takes about 1,000 kw. Fig. 3 is a section through this sub-station, and shows the arrangement of the switchgear. The high-pressure wires are brought in at the top of the tower, and immediately below on the top floor are the lightning arresters, *A*, and the water-resistances, *R*. On the first floor are situated the high-pressure oil-break switches, *H*, and on the same floor, but on the other side of a substantial wall, the low-pressure transformer switches, *L*. On the ground floor, immediately below the high-pressure switches, are the transformers, *T*, and the remaining compartment contains the distribution board, *D*. Fig. 4 shows the corridor containing the low-pressure transformer switches, and Fig. 5 is a view of the distribution board in the corridor on the ground floor. The signal lamps, the current

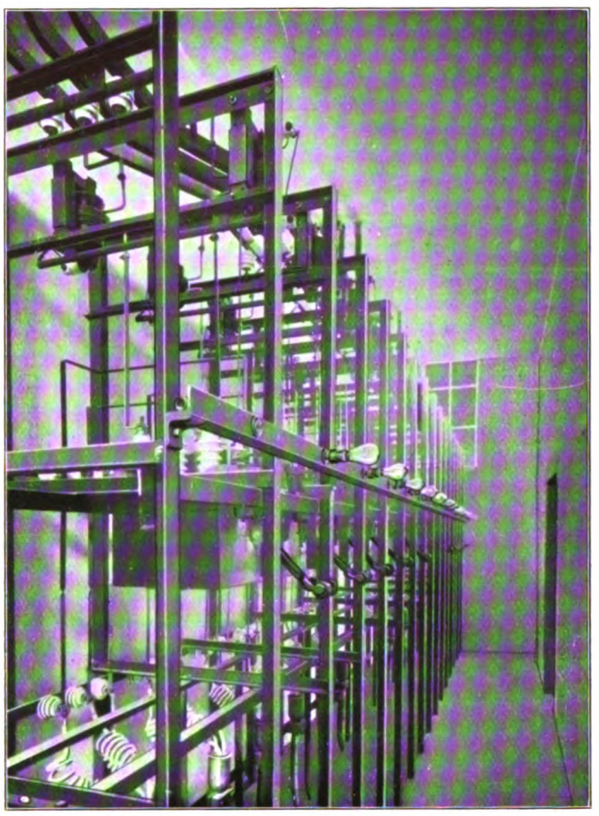

Fig. 5.—Distribution Board in Kriens Sub-station.

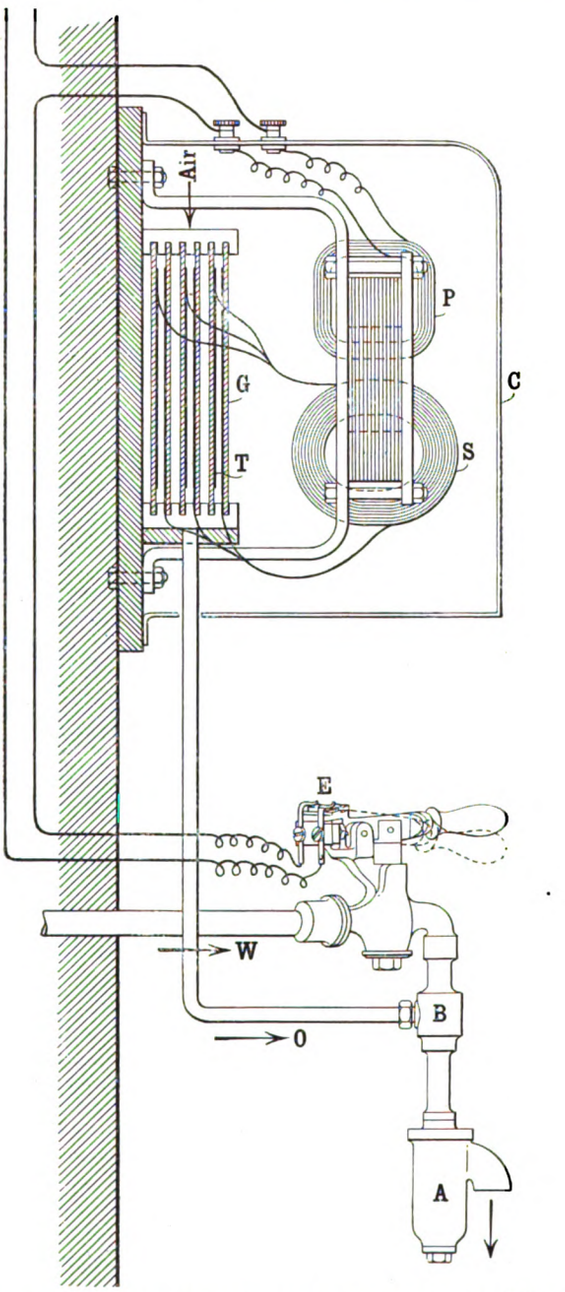
transformers, and the ends of the outgoing three-phase feeder cables are conspicuous in this last view.



With the exception of the high-pressure line itself, all the electrical equipment was supplied by the Oerlikon Co. On November 1st, 1904, the instalment of the electrical equipment was commenced, and on July 2nd, 1905, power was transmitted from Obermatt to Engelberg. On July 27th the tramway system in Lucerne was supplied from Obermatt, and on September 1st, 1905, the regular supply of both light and power to Lucerne exclusively from the power station at Obermatt was taken over. During the two years of working since that date no troubles worthy of mention have been experienced, in spite of the fact that many heavy storms were experienced in the district in the summer months.

The Batti-Wallah's Society.—The third annual dinner of the P. & O. Batti-Wallah's Society was held on March 7th at the Holborn Restaurant. An excellent musical programme was arranged. The President (Mr. Walter Riggs), replying to the toast of the President and Committee, reported on the gradually increasing membership, and said he hoped that the new clause qualifying electricians and electrical engineers who were not necessarily sea-going, or connected with the P. & O. Company, to associate membership, would result in a substantial swelling of their ranks. A number of new members were enrolled during the evening, and the announcement was made that a branch was to be inaugurated at Birmingham.

ELECTRICAL STERILISATION OF WATER

ELECTRICAL apparatus for the production of ozone has been on the market for some few years, but ozone as a means of sterilising water has not generally been known from a commercial point of view. The Lahmeyer Electrical Co. have on view at their offices in Oxford Street, a piece of apparatus which they have placed on the market, and which goes by the name of the "Otto Ozoniser." The apparatus on view is of the type used for installation in private houses for treating the drinking water instead of filters, and consists of a small transformer and ozoniser enclosed in a case a little over a foot square. A special tap and emulser, in which the ozone is mixed with the water, are also provided. If the supply is continuous-

Diagrammatic Sketch showing the principle of the "Otto" Ozoniser.

current, a small rotary converter, four or five inches in diameter, must be used to convert to alternating current. The principle of the ozoniser is best explained with the aid of the diagrammatic sketch shown above.

In the upper part of the sketch are shown the transformer and ozoniser in the metal case *C*. *P* is the primary winding of the transformer, which is supplied with current at from 100 to 250 volts according to the voltage of the supply mains or the converter. *S* is the secondary winding of very fine wire, which supplies current to the ozoniser plates at a pressure of about 15,000 volts. The ozoniser proper consists of six or more glass plates (*G*), supported on a grooved bracket at the bottom, and by grooved slips at the top and sides. Three pairs of plates are shown in the sketch. The inner sides are each provided with a coating of tinfoil (*T*), the opposing coatings being connected in parallel with the secondary winding of the transformer. The distance between the coatings is about one millimetre, and the layer of air is broken down, so that a continuous brush discharge takes place between the coatings. The oxygen in the air passing between the coatings is converted by the action of the brush discharge into ozone. The air enters at the top and sides of the battery of plates, and is sucked down through the opening provided in the lower bracket into the ozone pipe by the action of the water at the junction *B*. The water carries the ozone down with it into the emulser *A*, in which the two are mixed together, and the water thoroughly sterilised. As the transformer need be working only when water is being drawn, the primary switch is interconnected with the water tap as shown at *E* in the sketch. When the water is turned on, the primary winding, or in the case of a continuous supply the converter, is connected to the supply mains, and in a few seconds thoroughly sterilised water is issuing out of the emulser, at the rate of 60 gallons per hour. As the apparatus requires little more power than that corresponding to the no-load losses of the transformer, the consumption of energy is very low.

When first drawn, the water smells strongly of ozone, but in a few seconds the ozone has gone, leaving the water fresh and pure. According to the pamphlet issued by the Lahmeyer Co., the apparatus supplies some 8 to 10 grains of ozone per cubic metre of air, although much less would be sufficient to perfectly sterilise the water with which it is brought in contact.

Bacteriological analyses of samples of water treated in this way have shown excellent results, and we are informed that several municipalities, particularly in France, are adopting this system of putting down large and complete installations to deal with the whole town supply. The town of Nice has decided to instal the "Otto" system, and to electrically sterilise the water for the whole population, at present about 100,000 inhabitants. The city of Paris has also put down an installation to deal with a portion of the city's supply of water. The plant at Bon Voyage has batteries of ozoniser plates taking 2·4 kw. for each battery, and these are supplied from transformers, which transform up from 220 volts to 20,000 volts. In the larger plants, the ozone is pumped into mixing tanks, and these are filled with pebbles in order to ensure that the water is thoroughly broken up, and mixed with the ozone. Some of the larger installations deal with several millions of gallons of water daily. A portable sterilising plant has been designed for military use, and consists of a small petrol engine driving a water pump, an air pump, and a small alternator, a transformer, an ozoniser battery, and a mixing tank. Two filters are provided for filtering out suspended matter. The whole plant is mounted on a carriage, and is very compact. The capacity of the plant is about 500 gallons per hour.

The Fire at the Eiffel Tower Wireless Telegraph Station.—Some further particulars of the fire which occurred at the wireless telegraph station at the Eiffel Tower on February 17th are given in *La Lumière Electrique*. It appears that the fire originated in the condensers, the oil dielectric of which caught fire by some means not clearly understood. Experiments were in progress with regard to communication with the coast of Senegal, but it is not thought that these had anything to do with the cause of the fire, as at the time of the outbreak the sparking apparatus was not actually in operation. The statement which went the round of the Press that the damage done by the fire had interrupted all communication with the *Kléber* at Casablanca is contradicted, as it was only apparatus connected with the special experiments mentioned above which was destroyed, so that the service from the ordinary station was not interrupted.

Banquet of the American Institute of Electrical Engineers.—The American Institute of Electrical Engineers held a banquet at the Waldorf Astoria Hotel on February 19th. The gathering was called the "Public Service" banquet, from the fact that the control of public service corporations by the State is a topic now being much discussed in the United States, and that the speakers were asked to discuss themes connected with this subject. Mr. Stott, President of the Institute, was in the chair. Mr. W. C. Kerr, of Messrs. Westinghouse, Church, Kerr & Co., responded to the toast of "The Ethics of Public Service." Mr. F. W. Stevens, chairman of the second district Commune of New York, spoke on "State Control of Public Service Corporations." Mr. C. R. Huntley, of the Buffalo General Electric Co., also dealt with the same subject, and Mr. T. C. Martin, editor of our contemporary, the *Electrical World*, spoke on "The Technical Press and the Public."

11,000-VOLT OVERHEAD CONSTRUCTION

THE two illustrations below show the construction adopted by the Clyde Valley Electrical Power Co. for the 11,000-volt overhead lines that have been

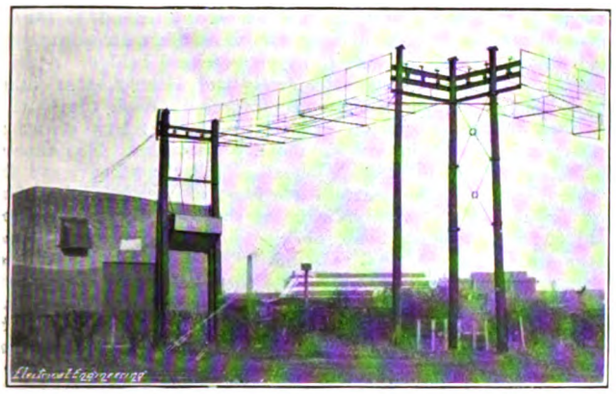

FIG. 1.—GENERAL VIEW OF 11,000-VOLT LINE, SHOWING GUARD-NET AND TURNING POLES.

they also supply and distribute to lighting loads in Clydebank and a number of districts in the Lanark

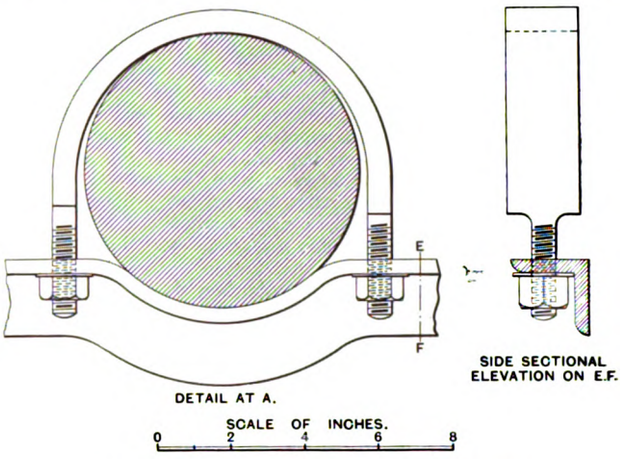

FIG. 2.—DETAIL OF SUPPORT FOR CROSS-ARMS.

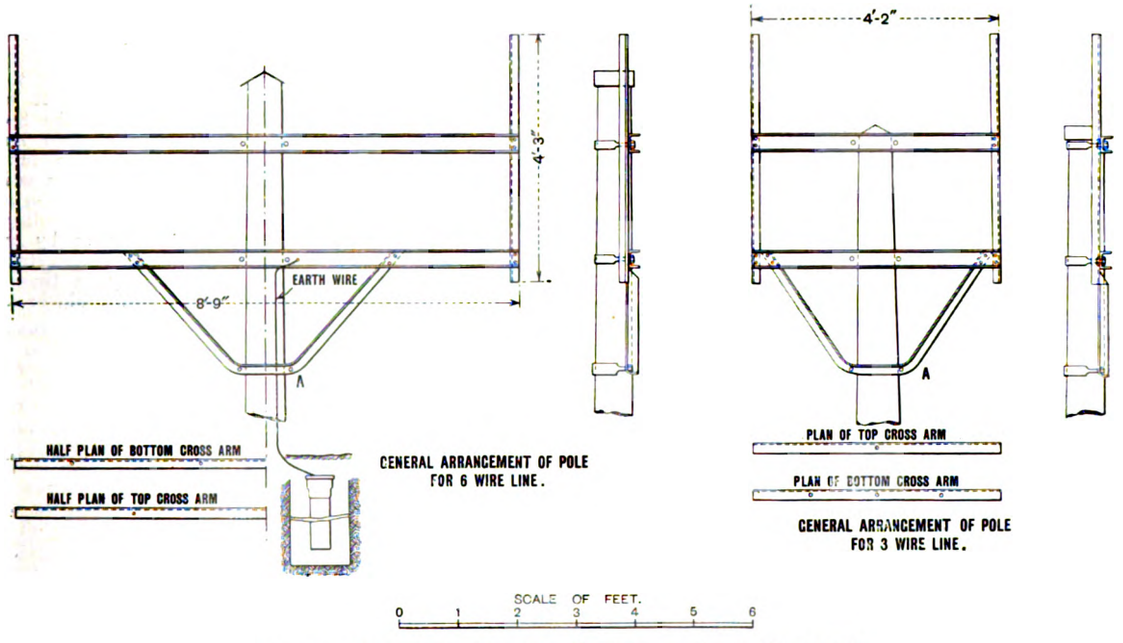

FIG. 3.—ELEVATIONS SHOWING DETAILS OF STEEL CROSS-ARMS.

permitted in their district. Fig. 1 is a photographic view of the turning poles which lead the lines into a sub-station, and shows the guard-net which is fixed in positions where the line crosses roads or paths. Figs. 2 and 3 are drawings showing the details of the steel cross-arms, &c. These cross-arms are connected by an earth-wire to a 6 ft. length of R.W. pipe embedded in coke breeze close to the base of the pole. The construction is employed for the line supplying the Motherwell Iron & Steel Works, described in our issue of February 27th. During 1907 the Clyde Valley Electric Power Co. have increased their output from 100,000 units per week to 11,000,000 units per annum, and their mains and distributors aggregate nearly 150 miles. Six shipyards, three steelworks, five rolling mills, eleven collieries, two foundries, and a large number of miscellaneous works are now connected to their power mains; and County Council district, and "in bulk" to the Corporation of Wishaw.

The Kelvin Lectureship.—At the meeting of the Institution of Electrical Engineers on Thursday, Colonel Crompton, the president, announced that the Council of the Institution have decided that the first Kelvin lecturer will be Professor Silvanus P. Thompson, F.R.S., and that the first Kelvin lecture will be delivered on "Lord Kelvin: His Life and Works," on April 30th, at the Institution of Civil Engineers, at 8 p.m.

The Under-running Third Rail System.—It is announced that the Belgian Government will adopt the under-running third-rail for its electric line at the Parc de Laeken, near Brussels. This decision was made upon the recommendation of Mr. Em. Uytborck, Electrical Engineer of the Government railways, who some months ago visited the United States and spent considerable time investigating heavy electric traction conditions here. Licence has been taken on behalf of the Belgian Government to use the Wilgus-Sprague type of protected third-rail, and orders for much of the necessary material, it is stated, have already been placed in America.

THE NEW YORK RAPID TRANSIT SUBWAY

A PAPER on the above subject was read by Mr. W. B. Parsons on Tuesday, February 25th, before the Institution of Civil Engineers.

The population of the city of New York is about 4,150,000, distributed among five boroughs. The railway described in this Paper is confined chiefly to the borough and island of Manhattan, the most important district of the city. The railway has been constructed by and at the expense of the Municipality, under the jurisdiction of the Rapid Transit Commission, through two contracts with one company. These contracts provided that the company should construct the railways for a lump sum in each case, payable in cash by the city as the work progressed; that it should furnish all equipment, to be taken over by the city on an appraised value at the termination of the leases, and to operate the railways for 50 years with the renewal period of 25 years. The rental during the first period is the interest on the city's bonds issued for the construction, plus 1 per cent. per annum for a sinking fund. For the second period the rental is to be fixed by arbitration.

The route begins at one of the suburban stations of the Long Island Railroad, in the borough of Brooklyn, passes under streets in that borough for 1½ mile, and thence in tubes under the East River, whose width at the point of crossing is nearly one mile; it then follows a central route under streets in Manhattan for about eight miles, where the line forks, one branch continuing north, the other north-east to the upper part of the city in the borough of the Bronx, giving a total length of route of 25·7 miles. It was in 1894 that the Rapid Transit Commission was appointed and the work projected; but for various reasons the latter was not begun until 1900. The author, as chief engineer to the Commission, after a study of the tubes in operation and under construction in London, advised that the converse extreme principle in design be adopted, and that so far as possible the railway be of "subway" rather than tube type, and be kept as close to the surface as local conditions permitted.

In New York, the demand for additional transportation, especially for long distances, was so great that the two tracks were recognised as being too few to carry the traffic, and especially to give the required high speed. It was therefore decided to construct four tracks, parallel, and usually on the same level, over the central section, where the traffic would be the heaviest, on which trains could run all day in both directions. The outer tracks were to serve the local traffic, with about four stations to the mile, while the inner tracks were to carry the fast service, with stations at intervals averaging 1½ mile. On the sections where traffic would be less heavy, three tracks were projected, the central one to give an express service in the direction of maximum demand; that is, towards the commercial district in the morning, and from it in the evening. Of the total route, 10·2 miles have two tracks; 7·6 miles, three tracks; 7·6 miles, four or five tracks; 0·2 mile, eight tracks, a storage yard; and 0·1 mile, one track, a terminal loop.

To support the street roadway, a flat roof was adopted, consisting of transverse beams set at 5-ft. spacing. From the surface of the paving to the top of the roof the minimum distance is 30 in., governed by the yokes of the surface electric tramway. The height in the clear from rail-level to underside of roof is 13 ft., and the width per track is 12 ft. 6 in. The internal diameter of a tube of corresponding capacity would be 15 ft. 6 in. This accommodates a car similar to the one in use on the New York elevated system, and much larger than any car in the London tubes, except the Great Northern and City. The minimum depth from street to rail-level is 17 ft., and to platform about 13 ft. Every effort was made to attain this last dimension at stations. In order to keep the subway dry, an envelope of waterproofing material was embedded in the concrete of floor, walls, and roof. This material was alternate layers of paper roofing-felt and carefully selected asphalt. This envelope was made continuous, and was protected from subsequent external injury by an external covering of concrete. This was found to work well against even a substantial hydrostatic pressure. Where, however, such pressure became considerable, layers of bricks, dipped in asphalt, were used instead. After the work had begun, a structure of reinforced concrete was designed instead of the beam construction, and has been largely used. The rows of columns between the tracks are retained, and, in order to economise space, such columns are of steel. A longitudinal truss of reinforced concrete connects the columns, while the roof and walls contain rods on the tension side. Wherever below the level of standing water, rods were embedded in the floor. Such construction, in practice, was found to be both cheaper and more expeditious than beam construction. Although the basis of the design is a shallow subway, with a flat roof, and constructed by "cut-and-cover" methods, there was no hesitation to depart from this type if conditions demanded or warranted such a course. There are 14·2 miles of cut-and-cover, of which 13 miles have a flat and 1·2 miles an arched roof, 3·9 miles of masonry-lined tunnels, 2·7 miles of iron tubes, and 6·6 miles in the open or on steel viaduct.

Stations for the local tracks, except in a few instances where island platforms were more convenient, have platforms on the outside with short direct stairways leading to the pavement. There are for each platform usually two exit and two entrance stairs. The express stations are served by island platforms, one between each pair of tracks, connected with each other and with the street pavements by an overhead bridge. At such stations passengers can transfer freely and without extra charge from local to express trains and *vice versâ*. Such transferring is done to an unexpected extent, the local trains acting as gatherers and distributors for the express trains. The express trains are scheduled to make about 30 miles per hour, and the locals 13 miles. There are 58 stations, of which all but four are reached by stairs only, while of the four, three have lifts, and one a moving staircase working in both directions. Junctions are arranged so that opposing tracks pass under and over, there being no level crossing. The sharpest curve where speed is possible has a radius of 458 ft., and the maximum gradient is 1 in 33, or less than 1 in 60 if accelerating is likely. The express tracks are wholly and the local tracks partly protected by automatic block signals, with emergency automatic stops. The permanent way is of the usual American standard with 100-lb. rails.

New Admiralty Wireless Telegraph Station.—It is stated that the Admiralty are about to establish a wireless telegraph station at Easington, in Holderness, the special junction of which will be to keep in touch with the North Sea fleet.

Interference with Wireless Messages.—According to the *Electrical Review* (New York), President Roosevelt transmitted to Congress on February 13th a letter from the Secretary of the Navy, recommending the enactment of laws making it a punishable offence "to originate or transmit a false wireless message purporting to be official, or to break in and interfere with any wireless station while it is transmitting an official message, or to refuse to cease or fail to cease sending a private wireless message when called upon to do so by an operator having an official message to be sent." The restrictions suggested are intended to apply particularly in times of peace. In times of war more rigorous restrictions would be indicated.

Proposed New Australian Electric Railway.—According to the *Australian Mining Standard*, it has been proposed to construct an electric railway between Collingwood and Doncaster (Victoria). The line would be a single one, and about 8¼ miles in length. Mr. M. Kernot, chief engineer for railway construction for the Victorian Railways, estimates that the cost of the line construction will be about £77,500, excluding power-house and rolling-stock. The power-house and plant would cost about £10,200, and the rolling-stock, consisting of ten motor-cars and five trailers, £13,500. This makes the total cost of the electric line amount to £101,000, whereas the estimated cost of the steam line is £166,000. The working costs, including everything, and with electric power supplied from the generating station at 1d. per unit, would come to about £17,950 per annum. On the present population there would be an income of not more than £2,000 a year, consequently the railway would not pay until there was a large increase in the population along the route.

Electric Cab Signalling in Germany.—A few notes on a system of cab signalling which has been introduced on the Prussian State Railways are given in an American Consular report. The purpose of the appliance is simply to give the driver warning at points about 100 yards before a signal. No attempt has been made to repeat the indications of the signals in the cab, as it is held that if he had only to observe signals in the cab, then the attention which it is his duty to devote to the road would greatly diminish. The watching from the locomotive, which is absolutely necessary for the safety of the train, would be gradually left unperformed, and the attention only directed to the little apparatus in the cab. Experiments in purely mechanical systems led to the adoption of an electrical contact apparatus as being the only form suitable for high speeds. At a fixed distance from the signal post two parallel iron bars with a small space between them are mounted along the track for several yards. There is attached to the locomotive an arm which carries a brush made of pliable copper wires. The passage of this brush between the iron bars produces a contact which is intense and free from concussion. An electrical action follows upon the mechanism in the cab, a bell sounds, and a white slide replaces a red. The sign remains plainly visible to the eye until the engineer presses a button. He knows definitely that a signal is to be expected, and if he cannot clearly make out the order intended, will stop the train.

OPENING OF THE HUDSON RIVER TUNNEL

THE first of the Hudson & Manhattan Railroad Company's tunnels under the Hudson River was formally opened for traffic by President Roosevelt on February 25th. The part of the route now opened consists of a twin-tube tunnel extending from Hoboken, on the New Jersey side, to Sixth Avenue and Nineteenth Street, New York, a distance of nearly three miles. This section is generally designated the Morton Street or "uptown" tube, and forms a part of the complete scheme of about 18 miles of track, the remainder of which is nearing completion. There are eight stations on the portion of the line now open, including the Hoboken station, and seven on the New York side of the river.

The project of building a tunnel under the Hudson River had its inception in 1878, when D. C. Haskins conceived the idea of constructing a brick tunnel from Hoboken to New York, through which he proposed to run railroad trains having a grand railroad terminal in the vicinity of Washington Square. His plan embodied simply a tunnel for the purpose of gaining access to New York for a terminal, and did not contemplate the extensive system of connecting lines now being completed. With much difficulty a company was formed to undertake the great work, and after a large sum of money had been spent, and about 1,200 ft. of tunnel built, the company failed, and in 1880 the undertaking was temporarily abandoned. In 1890 another company was organised with English capital, and the contracting firm of Pearson & Son, now engaged in constructing the East River section of the Pennsylvania tunnels, resumed work where the Haskins company had left it. This company, after adding about 1,800 ft. to the part already built, also failed, and once more the enterprise was checked. The original tunnel was constructed of brick and masonry in the old way, but it appears to have been the first time that compressed air had been used in horizontal work of this sort. In 1901, a company was formed by Mr. W. C. McAdoo to go on with the tunnel. The 3,500 ft. of old tunnel was acquired, and the tube finished with the steel-ring method. Work on the second parallel tube was also completed. These are the tunnels to be opened on February 25th, but to them has been added the extension under Sixth Avenue on the New York side.

The diameter of the tubes is 15 ft. 3 in. in the clear, and the depth of the tunnels below the surface of the Hudson River varies between 60 ft. and 90 ft. Under the river the tubes are about 30 ft. apart for the greater part of the distance. The system of separate tubes for north and south bound travel is maintained under Sixth Avenue and elsewhere in New York, although there the tubes are close together, and at passenger stations are joined so as to afford space for an island platform between the tracks. There are also side platforms as exit and egress platforms are kept separate. The use of separate tubes permits of ventilation by the piston action of the trains, which draws in fresh air from either end and forces the foul air out in front. In addition, the company has installed all along the line apparatus for artificial ventilation, which may at once be put into use if for any reason the tunnels or stations require an additional supply of fresh air. The whole cost of the system when complete will be 72 million dollars.

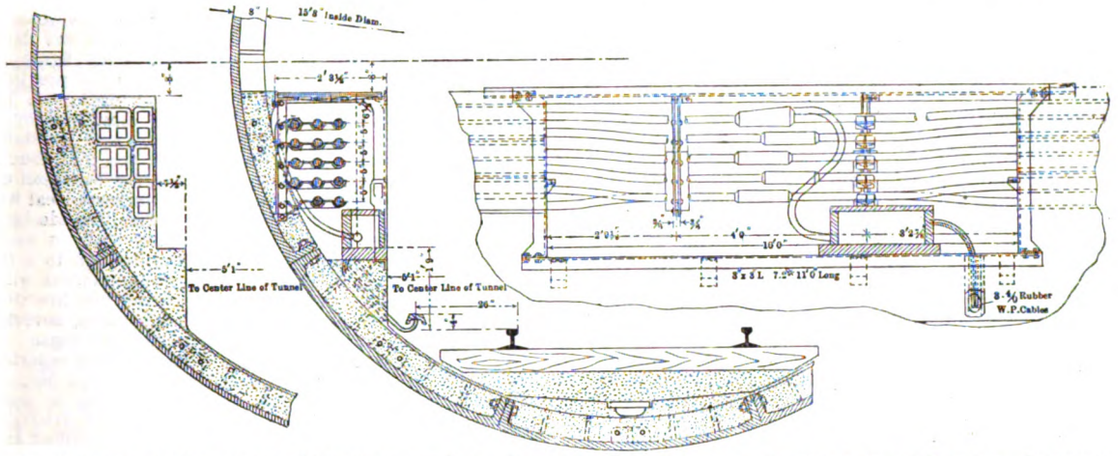

FIG. 1.—SECTION OF TUNNEL AND ELEVATION OF CABLE JUNCTION BOX SHOWING ARRANGEMENT OF FEEDERS, POSITION OF TRACK AND CONDUCTOR RAIL, &c.

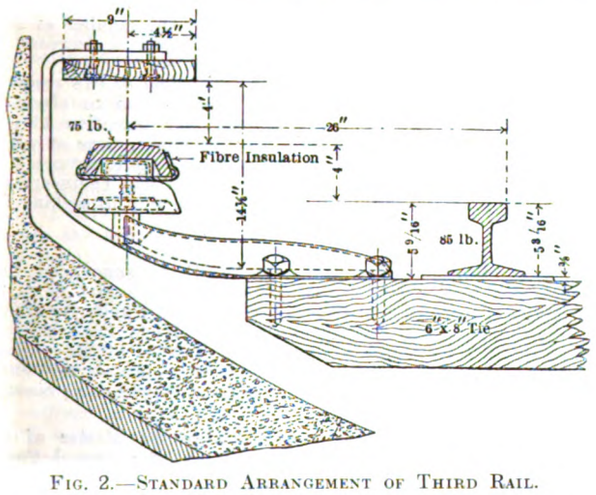

FIG. 2.—STANDARD ARRANGEMENT OF THIRD RAIL.

The arrangement of the third rail, which was designed by Mr H. Hazelton, electrical engineer to the Hudson Companies, and Mr. L. B. Stillwell, consulting engineer, is shown in the accompanying illustrations, which are reproduced from the *Street Railway Journal*, New York. Only one conductor rail is used, and this is placed outside the track. It is of inverted channel section, and is laid in 60-ft. lengths. It weighs 75 lb. per yard, and the composition of the steel is as follows:—Carbon, 0·10; manganese, 0·55; phosphorus, 0·10; sulphur, 0·08; silicon, 0·03. This composition gives a conductivity, as compared to copper, of 1 : 8·5. The third rail is bonded at every joint with two 550,000 circ. mil bonds. These bonds have compression terminals which extend through the head of the rail. After the heads are expanded they are filed down to give a smooth-running surface to the third rail. An angle plate is used at

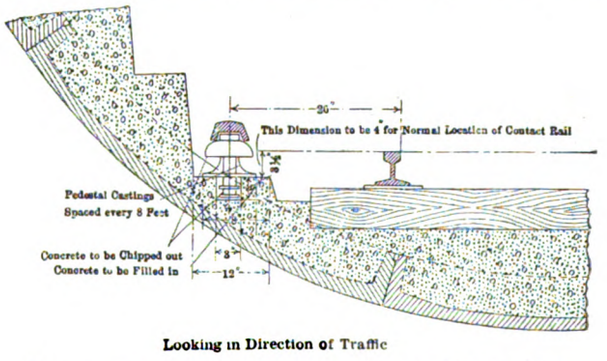

FIG. 3.—ALTERNATIVE ARRANGEMENT OF THIRD RAIL.

Digitized by Google

the third-rail joints, consisting of two clips 11½ in. long, clasping the lower part of the channels and held together by two ¾-in. bolts. The third-rail insulator is of porcelain, with double petticoat 7½ in. in diameter and 3½ in. high. It is mounted on a malleable iron pin, and is surmounted by a malleable iron cap on which the third rail rests. The third-rail insulators are spaced 9 ft. apart, and as a rule are supported on a malleable iron bracket which is held to the tie by screw spikes. Where the clearance would not admit of this construction a pedestal casting, illustrated in Fig. 3, is used, sunk into the concrete walls of the tunnel.

The third rail is anchored at its middle point by a special cap of malleable iron, and by a pair of angle plates. Where this cap is used the smaller cap is not employed. The bolts of the angle plate pass through the extension arms of the anchoring cap. A protection board is carried over the third rail, as indicated in the drawings. This protection is made of Jarrah plank, 2 in. by 9 in. by 9 ft., and is supported on brackets on every other tie or at 36-in. centres. The ends of the planks are joined by a special splice plate consisting of 3/16-in. steel, 9 in. wide and 6 in. long, and with a 1 5/6-in. channel bent down on each side to keep the planks in line. This splice plate is bolted over the top of the protection board with ½-in. by 2¾-in. bolts. The track rails are 85-lb. A.S.C.E. section, and are bonded with two 300,000 circ. mil protected bonds. Screw spikes are used for the track rails as well as for the third rail.

As the large power house which the company is constructing in Jersey City has not been completed, and as only a small portion of the system was put in operation February 25th, arrangements have been made for securing all of the power necessary at present from the New York Edison Company. Eight-car trains, electrically propelled, are used in the tunnel. The cars are made entirely of steel, and are constructed upon a plan differing materially from any others now used in the Metropolitan district. They have large sliding side doors in the middle as well as at either end, and the platforms are so arranged at the terminal stations that passengers enter and leave the cars at the same time. The doors are operated by compressed air, and no signal bells are used. When the last door in the train is securely closed, the motorman receives an electric flash signal and starts the train. The automatic adjustment is such that the signal to start cannot be given so long as any door in the train remains open for even a fraction of an inch.

The ventilation of the tubes is automatic, as each train acts as a piston, forcing out the air ahead of it and drawing in a fresh supply from the surface as it proceeds.

Tramway Rating.—In the King's Bench Division of the High Court on Friday, Mr. Justice Darling and Mr. Justice Phillimore, sitting as a Divisional Court, gave their reserved judgment in the motion which they had before them on Friday week, in which Mr. Page, K.C., who had with him Mr. Ryde, moved on behalf of the Guardians and Assessment Committee of the Hendon Union, for a rule *nisi* for a writ of prohibition, calling upon the Justices of Middlesex to abstain from hearing an appeal by the Metropolitan Electric Tramways Company, against their assessment, while certain magistrates, who are members of the Middlesex County Council, were on the bench. We gave full particulars of the action on p. 371 of our last issue. Mr. Justice Darling, in his judgment, said that the Tramway Co. had a tramway which was leased from them by the London County Council, which received 45 per cent. of the net profits. Some of the Justices who were going to hear the appeal were members of the County Council. The question was what would be the effect on the minds of the public as to the fairness of the administration of justice if these magistrates sat, and it was a question of degree. Any person might reasonably, though perhaps wrongly, object to these justices sitting, as what the Council would receive would be greater or less, according as the rates were less or greater. The applicants were therefore entitled to a rule *nisi*. However, the bias of a person was not always in the direction which charitable people assumed. He could imagine that there were people who were the friends of every parish but their own, but still their decision would be biassed. Mr. Justice Phillimore concurred, and the rule was accordingly granted.

Electric Lighting in Austria.—According to *Elektrotechnik und Maschinenbau*, the town of Beraun, in Bohemia, decided last year to have a central station, and a three-wire 2 × 220-volt direct-current system was originally proposed. In consequence of the success of the metallic-filament lamp, however, the generating plant and the distribution network have been installed for three-wire 2 × 120-volt direct current. Both public and private lighting is, with the exception of a few arc lamps, carried out entirely by metallic-filament lamps, the streets being lit by 50 c.p. 120-volt Wolfram lamps. The generating plant consists of two 66 kw. steam generating sets and a 400 ampere-hour accumulator battery.

FIRES IN LONDON DURING 1907

THE report of the Chief Officer of the London Fire Brigade for the year 1907 contains some interesting statistics relating to the fires which have taken place in the metropolis during the year. It is gratifying to note that the total number of fires, which was 3,520, was 523 less than during the previous year. The number classified as serious is, however, slightly in excess, being 70 as against 65. The number of lives lost has declined from 104 to 95. Considerable improvements are being made in the equipment of the brigade, and it may be mentioned that the number of street fire-alarms has been nearly quadrupled in the last eight years, and now stands at 1,285, and that there are now three stations where motor-driven appliances are used exclusively. Owing to the fact that the system of fire-alarms employed is such that the appearance of any defect acts in such a way to give an alarm, there have been no less than 549 false alarms due to this cause—including four from the derangement of automatic alarms—during the year. This figure, however, shows a reduction of 57 over the number in the previous year.

All the telephone exchanges situated within the county of London are now connected with the most appropriate fire-stations for distributing calls received for fire, but these are not necessarily the stations nearest either to the telephone exchange or to the subscriber. In cases of fire delay has been caused by persons asking to be connected with the nearest local fire-station. The best method of calling the London Fire Brigade by exchange telephone is, after getting communication with an exchange, to ask for "Fire Brigade," and on getting through to a fire-station to give the address of the fire, when the appliances will be sent. It is obvious that every fire-station cannot for fire purposes be connected with an exchange, as, in some cases, several stations are in the area covered by one telephone exchange.

A summary of the causes of the 3,520 fires reported during the year gives information regarding all except 343, which are classified as "unknown," and it is interesting to compare the comparative number of fires attributed to electricity and gas. The fires attributed to electrical causes are classified as follows:—Electricians at work, 1; defective electric circuits, 88; "overheat" of electric light, 2; vapour of spirit coming into contact with electric spark, 3; spark from electric arc lamp, 1. As against these 95 "electrical" fires, particulars are given of no less than 348 fires due to gas, classified as follows:—Swinging gas bracket, 13; overheat of gas engine, 1; escape of gas, 95; explosion of gas, 10; gasfitters at work, 13; gas light, 2; gas lighting, 5; clothes coming into contact with gas light, 1; curtains or window blinds coming into contact with gas light, 102; goods coming into contact with gas light, 8; linen coming into contact with gas light, 1; overheat of gas light, 12; spirit coming into contact with gas light, 2; seeking for an escape of gas with a light, 22; gas stoves, 17; clothes coming into contact with gas stove, 5; curtains coming into contact with gas stoves, 7; overheat of gas stove, 14; portable gas stoves, 14; geyser, 1; lighting geyser, 1; overheat of geyser, 1; petrol vapour coming into contact with gas light, 1. The total number due to oil and spirit lamps and stoves is 329. Only one fire is recorded as due to lightning. It should be noted that the number of fires attributed to defective electric circuits shows a decrease of 12 as compared with 1906.

From the table of causes of fires in which loss of life occurred it is seen that no lives were lost at fires due to electrical causes, although four fatal fires owed their inception to gas. Eleven fires took place at electric lighting works, none of which were serious, and six cases are reported of electric tramcars on fire, and eight fires on the premises of electrical engineers are recorded, one of which, curiously enough, is due to seeking for an escape of gas with a light.

Electric Automobiles in Hyde Park.—It is announced that licences and badges will be issued, after March 31st next, by the Commissioners of his Majesty's Works and Public Buildings, for the admission of electric carriages to Hyde Park between the hours of 4 p.m. and 7 p.m., in the months of May, June, and July. Forms of application may be obtained, by letter only, from "The Secretary, H.M. Office of Works, &c., Storey's Gate, Westminster, S.W."

Mersey Railway Contract.—On Saturday the Master of the Rolls and Lord Justice Buckley, sitting in the Appeal Court, heard an appeal by the British Westinghouse Manufacturing Co., Ltd., from the refusal of Mr. Justice Eve to grant an injunction restraining the Mersey Railway Co. from issuing the difference between £249,276 and £275,000 debenture stock at a higher rate of interest than 4 per cent., and from issuing the said difference, or the difference between £620,000 and £705,000 debenture stock, at any price lower than par without previous consent in writing of the plaintiffs in breach of an agreement of July, 1901. Full particulars of the point in dispute were given in our account of the action before Mr. Justive Eve in our issue for February 20, page 282. Their Lordships dismissed the appeal, holding that there was an obligation on the plaintiffs to purchase the £2,500 stock on January 2nd, 1908, which had not been done, and that the defendant company was released from all their obligations under clause four of the Works Contract.

FUSE PHENOMENA

Proposed Standardisation of Fuses

A PAPER by Prof. Alfred Schwartz and Mr. W. H. N. James was discussed at the Manchester Section of the Institution of Electrical Engineers on March 31st, and in London last Thursday. Although it dealt principally with the selection of a metal for fuses, the Paper was of unusual length, and we are, therefore, only able to publish it in an abbreviated form. From the discussion, it was elicited that the tests described have been made at the request of the Engineering Standards Committee.

Purity of the Metal.

The importance of employing a material which can easily be obtained of standard composition is generally understood; but, notwithstanding this, a very large amount of alloy wire and strip is still used, the composition of which is a very uncertain quantity. It is true that many of these metals have lower melting-points than those of the pure metals in use as fuses, but this does not outweigh the advantage which a pure metal such as copper possesses of constancy of composition.

Melting-point.

Fire Risk.—The fire risk with metals of low melting-point is due to the scattering of molten particles when the fuse blows, or to the persistence of the arc across the terminals. With metals of high melting-point, there is an additional risk due to the fuse becoming red-hot before fusion. The liability of some metals, such as zinc, to burn in air at the temperature of disruption must also be considered; and with enclosed fuses fitted with indicator wires, it must be borne in mind that this wire practically forms an open fuse of small capacity. Experience has shown that the flash from such an indicator is sufficient to ignite combustible material in the vicinity. Further, with enclosed fuses, unless hermetically sealed or provided with special arrangements referred to hereafter for preventing the ejection of molten metal, both flame and molten metal may issue from the ends.

Method of Connecting the Fuse to the Fuse Contacts on the Carrier.—In enclosed cut-outs the fuse is usually soldered to stout copper wires or lugs, which are in turn soldered to the metal end caps of the cartridge, extending inwards inside the cartridge for a considerable distance. With an enclosed cut-out of this character it is impossible to judge of the actual length of break employed, from a consideration of the outside overall length between the end caps or fuse contacts. Secondly, the four soldered joints, if not carefully made, may develop sufficient heat locally to blow the fuse prematurely or to char the jacket if a combustible material, such as red fibre, is employed. With metals of low melting-point this arrangement seems to be adopted to avoid damage to the end caps by the arc, and also to allow of the fuse being soldered to the lugs before being placed in the cartridge.

Jacket Material for Enclosed Fuses.—Fibre is easily worked, but is combustible, absorbs moisture, and deteriorates on heating. It can only be employed with fuse metals of low melting-points; the low melting-point of the metal does not prevent a high temperature being developed by the arc if this holds for any length of time. Fibre is used very largely in the United States, and possesses the advantage of being tough and not easily broken. Frequently the fixing of the end caps to the fibre tube is not substantial enough; where rivets are employed, they are commonly placed too near to the end of the tube, and the end caps are in consequence easily blown off. Glass is not much used for enclosed fuses, as it is not so strong as porcelain. Porcelain would seem to be the most suitable material for jackets; it, however, does not lend itself so easily to connection with the fuse contacts, and is also more expensive than fibre. At first sight the metal tube would appear to offer advantages from the point of view of incombustibility, strength, and cooling; its use, however, is complicated by the necessity of using an internal liner of insulating material. With regard to cooling, the jacket material does not usually play an important part, as this is largely determined by the character and disposition of the filling.

Specific Resistance.

On low-voltage circuits the resistance of the fuse itself forms a considerable portion of the total resistance of the circuit, and therefore plays a not inconsiderable part in limiting the current rush on short circuit. With higher voltages this effect is of less importance.

Liability to Oxidation.

Fuse metals may be grouped under the following three heads with reference to their oxidation:—

(*a*) Non-oxidisable metals and those in which the skin or sheath of oxide is fluid at the temperature of fusion of the metal.
(*b*) Oxidisable metals in which the oxide sheath is sufficiently strong to hold up the molten metal until evaporisation occurs.
(*c*) Oxidisable metals for enclosed fuses in which the oxide sheath is capable of combining with the filling, fluxing the latter and forming a sheath or tube.

Copper and silver may be placed in class (*a*). Copper oxidises slowly at temperatures under red heat, and as, in open-type fuses, copper only becomes red hot when loaded to 75 per cent. of its fusing current, this metal is suited for circuits which will allow of an overload of the order of 75 per cent. or upwards. At the temperature of fusion of copper the oxide sheath is fluid, and, as far as the holding up of the molten metal is concerned, it may therefore be considered as a non-oxidisable metal.

Class (*b*) consists of oxidisable metals, such as aluminium, zinc, cadmium, and tin, which are capable of forming oxide sheaths strong enough to hold up the metal after fusion. This effect is particularly noticeable with small round wires; with the larger wires and strips the mass of metal is usually sufficient to break through the oxide skin.

Class (*c*) includes enclosed fuses with silicious fillings, which are capable of combining with the oxide sheath and of forming a containing tube around the arc. Such tubes at the high temperature at which they are formed would very probably conduct after the manner of Nernst filaments.

Mass of Metal required for a given Service.

Although the quantity of heat in the fuse at disruption may be considered as some criterion for selecting a metal from the fire-risk point of view, yet in the authors' view this consideration is outweighed by others, such as the capacity of the metal for maintaining an arc, the surface tension of the molten metal as influencing the way in which it segregates into globules, the behaviour of the globules of metal after disruption as to whether they burn in air or not. In general, it may be taken that the mass of metal in the fuse should be kept as small as possible for open-type fuses; for enclosed fuses this point has to be considered in connection with the temperature which the jacket material will stand, as the metals with small mass necessarily have a high melting-point, and will attain red heat before fusion. In the screened shunted type of fuse it would seem possible to employ a metal with large mass and low melting-point for the main fuse, as this will melt quite quietly, the break being made on the shunt, which is of high resistance, and is enclosed or protected. For fuses of large capacity this type is worthy of more attention than has hitherto been paid to it.

Capacity of the Metal for Maintaining an Arc.

The authors have studied this condition in three ways: By photographing the fuse itself when blowing; by observing the minimum length of break at which, on short circuit, the character and duration of the arc is such that little or no damage is done to the terminals; by oscillograms of the current rush and inductive pressure-rise on short-circuit.

The Short-circuit Current.—The authors suggest that the drop in volts in the conductors on the generator side of the fuse (expressed as a percentage of the supply voltage), when these conductors are carrying the current which will melt the fuse, should be specified, so that the maximum value of the short-circuit current may be known. Thus a 3 per cent. drop in volts would allow of a short-circuit current equal to thirty-three times the normal fusing current of the fuse under test, a 10 per cent. drop of ten times the normal fusing current, and so on. Three per cent. drop in pressure was found to be representative of the conditions likely to be met with in house services for main and distribution board fuses. The minimum length of break referred to as the "minimum no-arc length" was taken as the least length at which no damage was done to the terminals on short circuit, the resistance of the circuit being such as to give a 3 per cent. drop with the normal fusing current flowing.

Experiments showed that there was a greater tendency for an arc to form across clean, freshly fused surfaces than across dirty surfaces. The authors found that for copper wires of 20 amperes N.F.C. (Normal Fusing Current) and upwards on a 220-volt circuit the minimum no-arc length increases slightly as

Digitized by Google

the drop in pressure in the circuit is reduced. The following values are each the result of about twenty experiments with a 27-ampere (No. 25 S.W.G.) open-type copper fuse with large terminals (350 gm.) on a 220 volt circuit :—

Short-circuit current in terms of the normal fusing current.	Minimum no-arc length in inches.
N.F.C. × 33	3·6
N.F.C. × 10	2·9

With the same size of wire, but small terminals, the authors obtained the following results :—

Short-circuit current in terms of the normal fusing current.	Minimum no-arc length in inches.
N.F.C. × 33	4·20
N.F.C. × 10	3·05

On the other hand, for smaller copper wires (Nos. 33 and 29 S.W.G.) in open-type cut-outs the minimum no-arc length seemed to be larger with a short-circuit current of ten times the normal fusing current than with a current thirty-three times the normal fusing current. The size of wire at which transition occurs seemed to be greater the lower the voltage of the circuit is and the more massive the terminals are. With enclosed fuses it was found that the results of short circuits were much more severe with 33×N.F.C. than with 10×N.F.C. This conclusion is based on a large number of visual observations; only a small number of actual determinations of minimum no-arc lengths were made, but these supported the above conclusion.

In all subsequent experiments, unless otherwise stated, 33× N.F.C. has been taken as the standard short-circuit current.

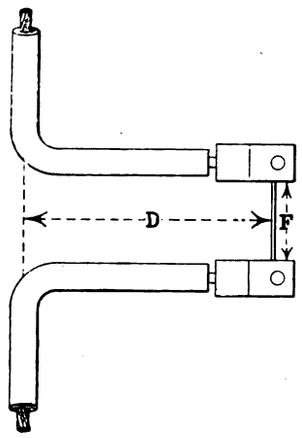

Fig. 1.—Arrangement of Wires to Fuse for Magnetic Blow-out Effect.

D. Distance through which leads are bent up at right angles
F. Fuse length.

Variation of Minimum No-arc Length with the Capacity of the Fuse, for a given Metal.—The minimum no-arc length for both open and enclosed fuses of a given metal increases with the capacity of the fuse, but not strictly proportionally.

Variation of Minimum No-arc Length with the Pressure of the Circuit.—Experiments were carried out at pressures of 110 and 220 volts on open- and enclosed-type fuses. They showed that for open-type fuses the increase in length of the minimum no-arc length is at least in proportion to the increase in the circuit pressure for the ranges given.

Variation of the Minimum No-arc Length with the Character of the Fuse Metal.—Under the same conditions in open-type fuses the minimum no-arc length for zinc is decidedly less than that for copper. Zinc blows fairly cleanly; the molten metal is not scattered far, but occasionally some globules show a tendency to continue to burn in air where they fall. On the whole it is a good material from a short-circuit point of view. Tin in open-type cut-outs with short-circuit currents of ten times the normal fusing current behaves very much like copper with short-circuit currents limited to two or three times the normal fusing current; that is to say, it blows softly and quietly, and it is difficult to state from visual observation when arcing takes place. It may be taken that the damage to terminals with tin in lengths commonly employed is slight with short-circuit currents of ten times the normal fusing current. With 20- or 30-ampere fuses and short-circuit currents of 33×N.F.C. there is, however, a great display of fireworks, accompanied by copious fumes, and with the lengths commonly used severe damage to terminals is likely to ensue. With enclosed fuses the minimum no-arc length was found to be somewhat greater for zinc than for copper; this is due to the greater mass of metal involved for a fuse of a given capacity and to the molten metal being confined by the filling, and possibly also to the metal vapour not being so quickly oxidised as when the fuse is in air.

That the different metals behave in a characteristic manner on fusion with regard to the duration of the current rush on short circuit, the tendency of the arc to persist, and the induc-

N.F.C. = 20 amperes.

tive pressure rise on breaking the circuit, was shown by a series of oscillograms.

Variation of the Minimum No-arc Length with the Inductance of the Circuit.—A consideration of these oscillograms showed that inductive pressure rises of as much as four times the circuit pressure may be met with in moderately inductive circuits. On non-inductive circuits the tests showed comparatively small voltage rises, and these were of short duration. Where present, the voltage rise occurs at two definite periods: firstly, when the current commences to fall, and, secondly, when it ceases.

Variation of the Minimum No-arc Length with the Disposition of the Cables to the Fuse Terminals.—In order to test the magnetic blow-out effect obtainable from the circuit conductors, the leads to the fuse terminals were bent through a right angle as shown in Fig. 1. It was found with this arrangement that the minimum no-arc length for open-type fuses could be very considerably reduced. For instance, with a 27-ampere copper fuse on a 220-volt circuit with leads bent up for a distance D = 4 in., the minimum no-arc length was 0·7 in., as against a length of 3·6 in. with the circuit cables entering the terminals in the ordinary way. Short-circuit current = 33 × N.F.C. The length was not materially increased with the bend in the leads reduced to D = 1 in., and even when an arc was formed it was of short duration and little damage was done to the terminals. This magnetic blow-out arrangement might well be taken advantage of in practice, as has already unwittingly been done with some

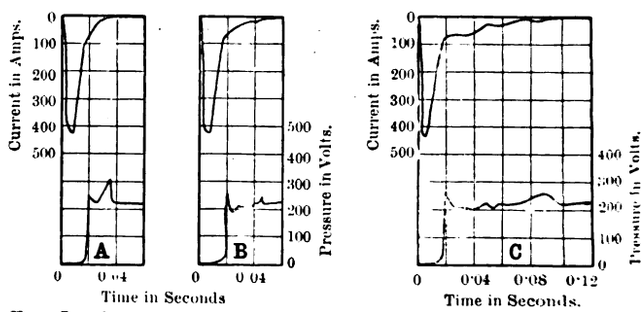

Fig. 3.—Oscillograms of Open-type Copper Fuse on 220-volt Circuit blown in a Longitudinal Magnetic Field, produced by forming the Lead to the Fuse into a Coil, through which the Fuse passed.

forms of knife-blade terminals, and terminals in which the cables enter from the back in contradistinction to the sides.

In order to obtain more direct evidence of the magnetic blow-out effect, a number of oscillograms were obtained for open- and enclosed-type fuses when blown in a magnetic field, first, at right angles to the length of the fuse, and then parallel to the length of the fuse. A selection of these is given in Fig. 2, which

Digitized by Google

shows the relative effects of these two dispositions for an open-type fuse when blown inside a field-coil spool which was separately excited. A longitudinal field was next produced by winding the lead to the fuse into a coil with a few turns through which the fuse passed; the results are given in Fig. 3. A consideration of this figure shows that the magnetic field is of considerable use in extinguishing the arc. Further experiments were made with the fuse wire doubled back upon itself for an inch, the legs of the loop being lapped with asbestos paper. The oscillograms are given in Fig. 4.

Extending the experiments on the magnetic blow-out effect to enclosed fuses, a small permanent magnet was first employed with but little effect. A solenoid was then arranged in series with the fuse, first, with lateral field, and then with longitudinal field; this resulted in both cases in the quicker rupture of the arc and an increased inductive pressure rise. The results are given in Fig. 5. A separately excited field coil gave similar results with both lateral and horizontal fields.

Variation of No-arc Length with the Mass of the Terminals.—The minimum no-arc length diminishes as the terminals are increased in size, and this effect is greatest with small fuses. This effect is probably not so much due to the cooling of the ends of the fuse by conduction (which for short-circuit currents of 33 × N.F.C. may be considered negligible, for the whole length of wire is almost instantly disrupted), as to the cooling of the arc vapour by the terminals. This cooling, taking place along a transverse section of the arc, introduces at each end a small section of high resistance which breaks down the arc.

Variation of No-arc Length in Enclosed Fuses, with the Character and Disposition of the Filling.—The formation of a slag tube around the fuse on disruption has already been referred to; the formation of such tubes would seem to depend on the

character of the filling employed, and to some extent on the character of the fuse metal. In general, silicious fillings favour the formation of these tubes, whereas cretaceous or chalky fillings do not. Metals with a high melting-point would at first sight seem to favour this formation, but it must be borne in mind that although the melting-point of a metal such as tin is low, yet the temperature of the arc following disruption may be, and probably is, as high as with metals of a higher melting-point.

The results given in Table I. are from experiments with various fillings in use commercially.

Table I.

Filling.	Remarks.
Calais sand	Forms tubes.
Coarse emery	Slight formation of tubes.
Fine emery	" " "
Trent sand	Does not form tubes.
Pumice	Forms tubes.
Chalk	Does not form tubes.
Crushed limestone	Very slight formation of tubes.

Apart from the formation of tubes and the absorption of moisture by the filling, the chief characteristics which differentiate the various materials used for fillings are the degree of fineness of the particles and the degree of tightness of the packing; the specific heat and thermal conductivity of the filling only influence the results indirectly, in that they affect the normal fusing current of the fuse. The normal fusing current for a given fuse is greater when enclosed and surrounded by a filling than when free in air from terminal to terminal. Experiments with a copper wire (N.F.C. in air 20 amperes) illustrating this point are given in Table II.

Table II.

Increase in Normal Fusing Current for Fuses enclosed in a Porcelain Tube ⅜-in. Internal Diameter with various Fillings.

Nature of filling.	Normal fusing current in amperes.

the normal fusing current, tubes of ⅜ in., ½ in., and 1 1/16 in. internal diameter were employed, and in each case for a copper wire with a Calais sand filling the fusing current was found to be 30 amperes. These and other experiments indicated that it is only a comparatively thin layer of filling round the fuse which exerts any considerable influence on the fusing current, and that this effect is due chiefly to the conductivity of the filling for heat.

It is probable that with tubes of very small diameter and with a small amount of filling the normal fusing current would not be increased so much as in cases given in the table above. Three experiments with a No. 27 S.W.G. copper wire N.F.C. in air 20 amperes, when passed through a clay tobacco-pipe stem, gave a mean result of N.F.C. = 28 amperes. The same size wire when passed through a braided asbestos tube had an N.F.C. = 22 amperes when the texture of the braiding was open, and 25 amperes when the texture was very close.

The effect of the size of the particles of the filling on the

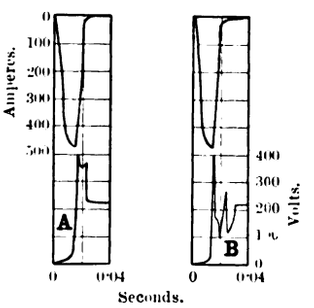

Fig. 6.—Oscillograms showing the Effect of the Size of Particles of the Filling on the Behaviour of an Enclosed Fuse.

duration of the arc is shown in Fig. 6. It will be seen that the more finely the material of the filling is divided the more quickly is the arc extinguished, and consequently the pressure rise on an inductive circuit would be high. This result is supported by a large number of oscillograms with various powders, both coarse and fine. The fine powders seem to be more effective in repressing the arc than the coarse ones, owing to their interstices being smaller and less air being included. This effect is linked with the degree of tightness with which the filling is packed: in the oscillograph experiments, the results of which are given in Fig. 6, the powders were not packed into the

Digitized by Google

tubes, but merely shaken down lightly into position. With the coarse filling the circuit was sometimes opened satisfactorily and sometimes irregularly.

Experiments were carried out with fillings of various degrees of fineness packed both tightly and loosely, and it was found that with fine powders the minimum no-arc length was shorter for both tight and loose packing than with coarse powders. This points to the presence of air spaces in the filling, due to the size of the particles of the filling being large, as having an adverse influence on the minimum no-arc length, since the tightness of

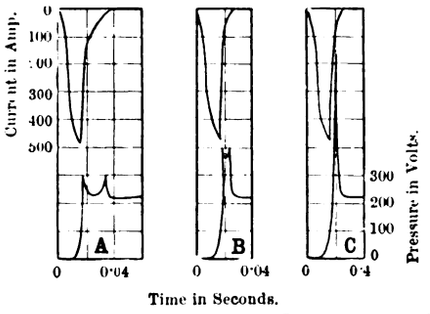

FIG. 7.—OSCILLOGRAMS SHOWING THE INFLUENCE OF TIGHTNESS OF PACKING IN THE FILLINGS FOR ENCLOSED FUSES.

the packing has but little influence in reducing the air spaces with coarse powders. Results illustrating this point are given in Table III.

Table III.

Effect of Tight and Loose Packing for Fillings of Enclosed Copper Fuses on 220-volt Inductive Circuit.

	Calais sand.	Trent sand.	
		Loosely packed.	Tightly packed.
27 amperes... ..	2·0 in.	1·4 in.	0·8 in.
43 „	2 2 „	1·4 „	1·0 „

With fine powders loosely packed there is a good deal of noise on disruption if the jacket is not hermetically sealed, and the filling is much blown about and some of it is compressed by the explosion against the inside of the tube. Loose fillings are therefore not to be recommended; and, further, when used vertically, as is nearly always the case, the filling will gradually settle together more closely, leaving a portion of the wire at the top end of the fuse exposed.

In order further to investigate the influence of tight packing, a series of experiments was carried out with fuse wires set in plaster of Paris. This practically amounts to a fuse with a very tightly packed filling; such fuses give a quick break, with a consequent high inductive pressure rise on inductive circuits.

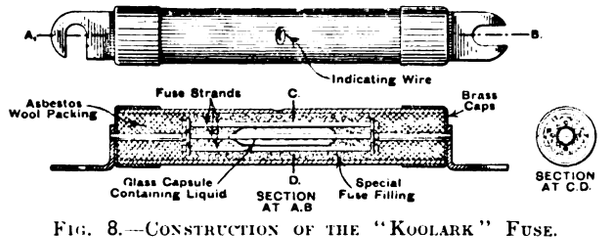

FIG. 8.—CONSTRUCTION OF THE "KOOLARK" FUSE.

Oscillograms on this point are given in Fig. 7. In general, these fuses blow very quietly, provided that the plaster covering does not crack or rupture; when this occurs bad arcing frequently results, and a loud report is produced. It is essential that the whole length of the fuse wire should be embedded in the plaster; this can be effected by soldering the fuse to stout copper connecting wires, one end of the wire being connected to the fuse contacts, while the other is embedded in the plaster. A containing envelope or jacket, even if only of slight mechanical strength, is essential for plaster fillings.

The presence of moisture in the filling may affect the fuse in the following ways:—(*a*) By actual combination with the filling material, causing it to set or otherwise altering its condition, *e.g.*, plaster of Paris; (*b*) a filling which has been moist may on subsequent drying become more or less coherent or caked; (*c*) an absorbent filling or a hygroscopic one will affect the arc disruption by cooling it, but may give rise to considerable pressure due to the generation of steam. It will also give rise to electrolytic corrosion in course of time; (*d*) The filling may be normally dry, the liquid being held in a special vessel or container, and is only liberated on a short circuit taking place when it extinguishes the arc. With enclosed fuses in general the jacket affords considerable protection from moisture, and the filling materials usually employed do not cake or cohere. Moisture in the filling, however, is not unusually present in commercial forms of fuses in red fibre jackets, as it exudes on tests when the fuse becomes hot. The closing of the vent holes of such fuses with a disc of glazed paper does not seem to be a very efficient means of preventing the ingress of moisture in damp situations.

Experiments were made with Calais sand as representing a silicious non-absorptive filling. Oscillograms of a copper fuse on a 220-volt inductive circuit with fillings containing up to 12·8 per cent. of water by weight showed that no very marked effect is produced on the action of the fuse by moderate amounts of moisture in the filling, but that when in excess—with 12·8 per cent. of water the filling was almost "sloppy"—it produces irregularity of action in the fuse.

Experiments were then made with a filling of Trent sand; this is much finer in texture than Calais sand, and absorbs water

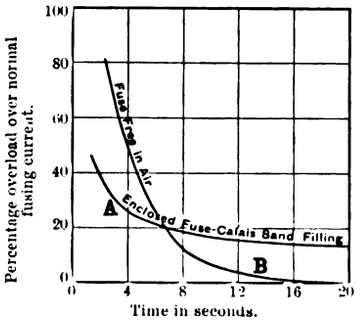

FIG. 9.—RELATIVE TIME ELEMENTS FOR COPPER WIRES WITH APPROXIMATELY THE SAME N.F.C. IN AIR AND IN CALAIS SAND. FUSES INITIALLY COLD.

A. N.F.C. in air = 32 amperes.
B. N.F.C. in Calais sand = 30 amperes.

freely, ultimately forming a mud. As the percentage of moisture in the Trent sand was increased, the action of the fuse became irregular, but with the moderately wet sand tightly packed a quick break and high voltage rise resulted. In this series of oscillograms of fuses in Trent sand, which are not reproduced here, the arc was broken very quickly, due probably to its being cooled by the evaporation of the water. This point is of interest in connection with a type of fuse recently placed upon the market in which a special liquid enclosed in a small glass tube is disseminated throughout the filling when the fuse is subjected to a short circuit. When the fuse blows with a moderate overload the glass tube is not broken and the filling remains dry. The construction of this fuse is shown in Fig. 8.

Although moisture in the filling may not very seriously affect the action of the fuse as far as the suppression of the arc is concerned, its presence in enclosed fuses is not at all desirable, as it would certainly lead to corrosion and electrolytic troubles, particularly if a contact difference of potential exist between the fuse and the wire or lug connecting it to the fuse contacts.

TIME ELEMENT.

Relative Time Element for Open and Enclosed Fuses with the same Normal Fusing Current.—A copper wire in an enclosed cut-out with Calais sand filling was found to have a normal fusing current of 30 amperes. A second copper wire was then taken and drawn down so as to have as nearly as possible this normal fusing current in air. The time elements for these two wires were then found for various overloads, and the results are shown graphically in Fig. 9, where the crossing of the curves owing to the smaller amount of metal in the enclosed fuse is clearly shown.

Temperature Rise for Jackets of Enclosed Fuses.—The chief factor which determines the temperature rise of an enclosed fuse as measured by the external temperature attained by the jacket is the melting point of the metal employed, metals with high melting-points on continuous overloads giving a higher

Digitized by Google

external temperature on a jacket of given diameter than those of greater fusibility. Experiments were first made with jackets of red fibre. Copper gives the highest temperature-rise, but when running at 50 per cent. of its normal fusing current (*i.e.*, when rated to blow with 100 per cent. overload) the temperature attained even at full load is not excessive, and when running at the rating given in the Institution Wiring Rules, namely, 200 per cent. overload for fusion—the external temperature of the jacket does not differ very materially from that obtaining with zinc and tin.

In order to determine the effect of the jacket material on the external temperature attained similar tubes of red fibre and of brass were next employed as jackets. The difference in temperature rise with a given load in the two cases was found to be very slight, the external temperature of the metal tube being slightly higher than that of the fibre tube. A short series of experiments were carried out to determine the effect of high temperatures on red and black fibre, with the following results :—

1. Red and black fibre heated at 180° C. : A slight amount of moisture came off in the form of steam, but there was no charring.

2. Red and black fibre heated to 210° C. for forty-five minutes : The specimens got very dry but were not apparently charred.

3. Red and black fibre heated to 240° C. : The specimens first became brittle and then charred.

With material composed largely of vegetable fibre brittleness and charring may be induced by exposing it for a long period of time to temperatures considerably lower than those referred to. With fibre tubes charring frequently occurs as the result of a short circuit, and even if it does not show on the outside of the jacket an examination will frequently show that the inside surface has been blistered.

Note on the Rating of Fuses.

A good deal of confusion exists as to the rating of fuses owing to the variety of conditions on which this rating may be based. The following suggestions are therefore put forward with a view of eliciting discussion on this point, and of possibly clearing away some misconceptions.

The fuse may with advantage be designated by the normal full-load current of the circuit on which it is to be employed. Thus, a "50-ampere fuse" would mean a fuse for the protection of a circuit the normal full-load current of which is 50 amperes.

The figure obtained by dividing the maximum permissible overload by the full-load current of the circuit represents the "sensitiveness," or, more correctly speaking, the insensitiveness of the fuse.

The normal fusing current for a given line of fuses should be obtained by the manufacturers or by an independent testing authority, and the fuses marked with their rating before being placed on the market.

In the United States the regulations given in the National Electric Code (1905) as regards rating are as follows :—

Open-type Fuses.—Must be stamped with about 80 per cent. of the maximum current which they can carry indefinitely, thus allowing about 25 per cent. overload before the fuse melts.

Note: With naked open fuses of ordinary shapes and with not over 500 amperes capacity the *minimum* current which will melt them in about five minutes may be safety taken as the melting-point, as the fuse practically reaches its maximum temperature in this time. With larger fuses a longer time is necessary. This data is given to facilitate testing.

Enclosed Fuses.—With the surrounding atmosphere at a temperature of 75° F. they must carry indefinitely a current 10 per cent. greater than that at which they are rated, and a current 25 per cent. greater than the rating, they must open the circuit without reaching a temperature which will injure the fuse-tube or terminals of the fuse block. With a current 50 per cent. greater than the rating, and at a room temperature of 75° F., the fuses starting cold must blow within the following times :—

Capacity of fuse.	Time.
0–30 amperes	30 seconds
31–60 ,, ...	1 minute.
61–100 ,, ...	2 minutes.
101–200 ,, ...	4 ,,
201–400 ,, ...	8 ,,
401–600 ,, ...	10 ,,

Note on the Time Element of Fuses.

The time element of a fuse may be defined as the time lapse necessary for the heating of the fuse from the cold state to the fusing-point with a given overload. The heat capacity of a fuse will be proportional to the mass heated, the average specific heat of the mass, and the temperature rise from the cold state to the melting-point. With enclosed fuses this heat capacity will vary with the character of the overload, since with large overloads there is insufficient time for the conduction of heat from the fuse to the filling, and the temperature rise of the latter is consequently small. Apart from the above consideration the time required for reaching the fusing-point is for a given fuse inversely proportional to the square of the current. The heat capacity of a fuse may be varied by changes in the fuse metal, the shape of the fuse, or the environment of the fuse. These variations may be made use of for altering the time element of a fuse for a fixed rating to a considerable extent. The greatest difference in time element will be between an open fuse of copper and an enclosed fuse of a sluggish metal such as tin or zinc; Fig. 10 shows the relative time elements of such fuses with a fusing current of about 250 amperes. The results given are collated from Meyer's* experiments for copper fuses and from Edward Taylor's† tests on enclosed fuses. These curves show that with an overload of 50 per cent. the time elements for enclosed and open fuses are as 4 to 1 and at 25 per cent. overload as 7 to 1. The above considerations hold for fuses of the same rating; the time element for a given type of fuse will, of course, vary with the capacity of the fuse.

It is desirable that a definite basis for reference should be established for the time element, and the authors suggest that the time element of a fuse should be defined as follows :—"The time element of a fuse is that time which is required to heat up the fuse from the cold state until it blows with an overload of 50 per cent. reckoned on the normal fusing current of the fuse."

For large-size enclosed fuses the time element as defined above

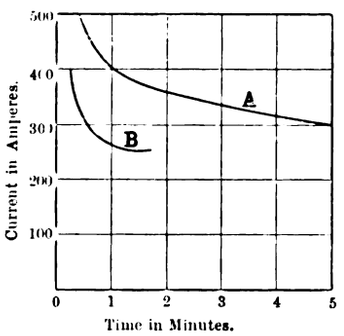

Fig. 10.—Relative Time Elements of Enclosed and Open-type Fuses.

N.F.C. about 250 amperes.

A. Zinc enclosed type.
B. Copper open type.

would be of the order of four or five minutes. For metals with low melting-points the time element will be increased if the external temperature is high.

Note on Short-circuit Currents.

It is evident that the position of a fuse on a system with reference to the generators will largely determine the character of the current rush on short circuit; it would therefore seem advisable that fuses should be tested with the short-circuit currents which would be likely to be met with in the class of circuit which they are intended to protect. It should not be expected, for instance, that a fuse on a distribution board in a house installation should be tested on a dead short circuit across station bus-bars. The authors have restricted their paper to a consideration of fuses up to 50 amperes for house service, and in this class of installation the maximum drop in volts with the full-load current is usually limited to 2 per cent. With the fuse rated to blow with twice the full-load current this maximum drop would be doubled, so that as an average value with the normal fusing current of the fuse flowing in the circuit a drop of 3 per cent. may be taken; this value is also supported by experimental evidence. As already pointed out, this arrangement neglecting the resistance of the fuse allows of a short-circuit current = 33 × N.F.C. of the fuse.

Whether a fuse on short circuit blows before the current has time to reach the value limited by the resistance of the circuit depends upon the nature of the fuse, the amount of the short-circuit current relative to the normal fusing current and upon the inductance of the circuit.

The German regulations as to short-circuit tests are as follows :—

"The output capacity of the source of current and the resistance of the leads are to be so arranged that at the time the fuse blows the total fall of pressure in them shall not exceed 1 per cent. These conditions will be regarded as being fulfilled if in the place of the fuse an adjustable resistance is placed arranged

* *Zur Theorie der Abschmelzsicherungen*, R. Oldenbourg, Berlin, 1907.
† *Street Railway Journal*, vol. 25, p. 548, 1905.

Digitized by Google

to carry a current of twenty times the normal carrying capacity of the fuse (this current must not, however, be less than 400 amperes), and at the same time the pressure across the terminals of this resistance must not be less than the normal pressure of the circuit for which the fuse is intended, the drop in the rest of the circuit being not more than 10 per cent. of this. When matters have been arranged to comply with the foregoing conditions the switch is to be opened, the resistance removed, and the fuse replaced. On closing the switch the fuse must melt without maintaining an arc and without explosive violence."

The authors found that when the short-circuit current was limited to 30 or 40 times the normal fusing current for a 20-ampere fuse, the magnitude of the short-circuit current was independent of the capacity of the generators employed within the following limits:—(1) A 50-kw. machine; (2) four 100-kw. generators with a 450 ampere-hour battery in parallel. It would seem, therefore, that if the current rush on short circuit is limited as above for testing purposes, the capacity of the generator need only be such that it will not be seriously overloaded by the short-circuit current in question. Since the duration of the short-circuit current is so small, being of the order of a few hundredths of a second, the voltage of the machine is maintained. In the authors' experiments two or three 100-kw. machines were employed in parallel with the battery mentioned above.

Note on the End Caps of Enclosed Cut-outs.

In enclosed cut-outs in which the fuse wire or strip is carried through a hole or slot in the end cap or ferrule and then secured by solder or in a terminal of some sort, it is necessary to protect these holes from damage from the arc, particularly if they are used as gauging devices to limit the wire or strip employed to a predetermined size. If the distance between the end caps is such that an arc can be set up between them, the hole or slot will either be considerably enlarged or damaged by fusion, or the wire or strip ends will become fused to the caps. This can be prevented by a device due to one of the authors, in which the fuse wire or strip before entering the hole or slot in the end cap or fuse contact makes contact with a washer or other easily renewable metal piece which is in electrical contact with the end caps or fuse contacts, and is therefore at the same electrical potential as they are. The damage will then be confined to the removable metal piece. It would appear advisable to do without free holes or openings in the end caps as far as this is possible, as they not only allow of the emission of flame on short circuit, but seem to favour the persistence of the arc.

DISCUSSION IN LONDON, MARCH 3rd.

Mr. Leonard Andrews, referring to the curious effect of the minimum arc length, namely, that it seemed to be larger with a short-circuit current of ten times the normal fusing current than with thirty-three times the normal fusing current, said that this peculiar feature had been noticed by many who had experimented with fuses. The authors suggested one or two explanations, one of which was that the magnetic blow-out effect due to the larger current in the leads might assist to extinguish the arc. He carried out a number of experiments at Hastings on high-tension fuses, and came to the same conclusion, namely, that the magnetic blow-out effect had a great deal to do with it. A great many of these experiments had been illustrated and described in his book on "Electricity Control," but there was one experiment, not referred to there, which appeared to him to

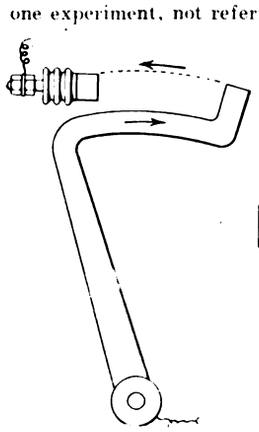

Fig. 11.

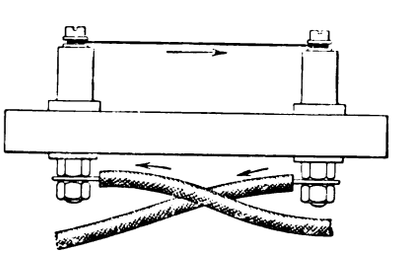

Fig. 12.

Mr. Andrews' Experiments.

show particularly that there was some truth in the author's suggestion. He was endeavouring to utilise this magnetic blow-out effect to extinguish the arc on a high-tension switch in the manner indicated in the diagram above (Fig. 11). It was before the days when they recognised that an open arc was a very bad thing to use. The direction of the flow of current in the switch-blade is opposite to that in the arc, and the latter is repelled. He found that with a 4 in. or 5 in. break, a current of about 100 amperes at 2,000 volts was interrupted reliably every time the switch was opened, whereas with a current of less than 50 amperes the arc was maintained. He also asked whether the authors had tried the experiment of crossing the conductors, as shown in Fig. 12. His experience in carrying out this experiment was that the magnetic repulsion effect was very largely increased. He found, in fact, that the arc from a fuse having a normal fusing capacity of 200 amperes stretched across a pair of terminals 6 in. apart was reliably interrupted when short-circuited across the poles of a 2,000-volt Mordey alternator, whereas with the leads carried straight into the terminals without crossing the minimum no-arc distance would probably be three or four times this length. It appeared to him that this principle might be applied to low-tension fuses with some advantage, at any rate, on alternating-current circuits, where a rapid interruption to the arc would not cause an injurious inductive pressure rise. Early in the Paper the authors had stated that with enclosed fuses they had found the results of short-circuits much more severe with thirty-three times the normal fusing current than with ten times the normal fusing current. This had not been his experience with high-tension fuses. He had frequently experienced cases of fuses of comparatively small capacity entirely failing to break the arc on short-circuits that probably did not amount to more than two or three times the normal fusing current, whereas similar fuses had operated perfectly on very much heavier short-circuit currents. He remembered discussing some years ago with an engineer in America, who had experimented a good deal with fuses on 20,000-volt circuits, and he had informed him that they often found that fuses on their extra high-tension lines worked perfectly on heavy short-circuits, such as might result from direct contact to earth, whereas they entirely failed to interrupt the arc on a slight overload that might be just sufficient to melt the fuses. It was probable that the phenomenon might be due, as the authors suggested when speaking of open fuses, to the fact that with a heavy short-circuit current the fuse wire is entirely volatilised, whereas with a slight overload the wire is melted into one or two pieces only, with the result that a small chain of arcs is formed between the terminals.

Mr. Alexander Russell thought that the Paper would form a partial basis upon which fuses could be rated, but in this connection they would have to consider the effects of voltage which the authors had not taken into account very fully. On the question of the choice of metal for a fuse, he mentioned that the interior of an aluminium or zinc fuse at the moment just before it fractured was molten. In the case of aluminium, the latent heat was 77 and the specific heat 0·3, whilst the melting point was 657. This showed that at the moment of rupture about 30 per cent. of the heat in the fuse was due to the latent heat. The latent heat and vaporisation of the metal should also be taken into account, and possibly the thermal conductivity. It might also be a question whether the most economical fuses to use with the various metals might not be of different lengths. He took it that what happened in the case of a fuse going was that it simply burst all along its length, much the same as a pipe would when the pressure inside became too great. With an aluminium fuse, for instance, the temperature in the interior was considerably higher than on the outside, due to the fact that the outside oxidised, and the oxidised metal was a worse conductor than the pure metal in the interior. It might be objected that he had neglected the skin effect, that when there was a sudden rush of current passing through a fuse, the current would be on the outside, owing to skin effect, but the oscillograms which had been exhibited proved that the skin effect would be quite negligible. The difference of temperature between the inside of the wire and the circumference depended upon the conductivity of the wire, and it was only appreciable when the current density was exceedingly high. In the case of a trolley wire, the difference of temperature at the centre and on the outside was possibly only $\frac{1}{1000}$ C., but in the case of a fuse, when the current density was so enormous, and for different metals than for copper, the difference of temperature was very high. This caused the metal inside to melt, to vaporise, and finally to explode, spurting the metal sometimes five or six yards away and making a report like a pistol-shot.

Mr. W. H. Patchell said the authors appeared to have found out that zinc and aluminium were both bad for fuses, because they oxidised. Years ago the same thing had been found out, and such fuses were given up on that account. In damp cellars they got skins such as were made by caddice-worms, namely, hard scales outside. The *bonâ-fide* metal inside then carried the current long after the metal had melted. He had had to go into the question of fuses several years ago, more particularly for street work. Some people had tried fuses at the end of the feeders, but he did not like them there because the current was too great. With house fuses they never had any trouble if they put in fuses that were large enough, in other words, they could let the consumers' fuses melt and still be quite happy, because the supply authorities would not be sent for. But for street work, in which the districts became bigger and bigger and more important, an accident on one side must

Digitized by Google

not be allowed to interfere with the rest of the network, and therefore it was necessary to limit, as far as possible, the extent of the damage. They had tried light fuses which could be put in at certain places where the areas joined, and where they had only to carry what might be called the balancing current between the different areas. The main consideration, then, was to have a fuse which would not cause a gas explosion in the street boxes. He had tried various forms of network fuses, including enclosed fuses. He started, of course, with those mentioned by the authors, which were enclosed in cylinders of red vulcanite. These were not satisfactory on account of damp; then they tried metal casings. They finally got on to a form similar to Peard's patent, and this type had been evolved into a form which was a fuse in a piece of common steam-pipe. They also sent round to all the different makers of silent fuses and gas-proof fuses, and some were obtained, but one day, whilst a Board meeting was being held in a room overlooking one of their sub-stations, there was a tremendous explosion, and on inquiry it was found to be a mains superintendent testing a silent fuse. They also tried various methods of filling tubes. They had not tried Trent sand or Calais sand; in fact, he would like the authors to say what was the difference between these two. Was one a slag sand, and did the other have rather more alumina in it? [Prof. Schwartz was understood to express assent.] He had tried marble dust and plaster of Paris, and could not find anything better than the latter. It did not matter whether it was poured in wet or put in dry. The authors had referred the question of the power behind the fuse. He had heard experimentalists say that this made no difference; but this was not his opinion from experience. He had tried fuses at 100 volts which acted quite well, and the arc did not carry over. On trying the same fuses on 200 and 400 volts they quite failed. The one difficulty in connection with fuses was to secure blocks to carry different sizes of fuses. At present they only had blocks which would carry a particular fuse. With regard to rating, there were all sorts of ratings; sometimes 100 amperes meant a fuse which would blow at this current, and another time a fuse which would carry 100 amperes to blow at 200 amperes. He would like some definite ruling as to how the fuse should be rated. He thought it was an open secret that a part of Prof. Schwartz's experiments had been carried out at the instigation of the Engineering Standards Committee, and it was a pleasure to get a little ahead of the Standards Committee and be enabled to discuss Prof. Schwartz's Paper. For heavy currents fuses had practically been given up entirely, and automatic switches employed as the only practicable substitute. He had seen heavy fuses for low tension with a shunt fuse in parallel, which was supposed to go last, but he had never tried this arrangement. For high-tension work, when he started at 10,000 volts, he used two fuses in parallel, one in a tube open at each end about a foot long and with the terminals about 12 in. apart. Alongside of it was a *small* tube $\frac{1}{8}$ in. in diameter, and a small fuse was threaded in this; but the big one would not go until the small one went. He then tried oil fuses for 1,000 volts continuous current. For several years he had used the Ferranti fuse, but it was impossible to calibrate this owing to the cooling property of the oil. He then adopted the calibrated oil type fuse, which was illustrated in his Paper on the Bow Works. Although this was called an oil fuse, the fuse was just above the surface of the oil as regards the actual visible portion, in a little inverted cup. As soon as the fuse acted it was drawn down into the oil before really there was any time for a surge to take place. This had the advantage that the visible portion was in action, and it was possible to calibrate without the interference of the cooling effect caused by the oil. He had also tried sparklet fuses for heavy currents, but had not adopted them.

Mr. C. C. PATERSON said that in 1902 some tests on sparking in switches carried out by himself and Mr. Alexander Russell, were published in the Institution Journal. The distance which they called the safe sparking distance came out in the case of switches at 50 per cent. greater than the authors gave as their minimum no-arc length. This was understandable, because in a fuse it did not matter if the contacts got a little damaged, whereas in a switch they wanted to avoid this.

Mr. W. M. MORDEY said the experiments which he had made upon enclosed fuses 17 or 18 years ago—and which he had almost forgotten—induced him to come to the same conclusion as the authors in giving preference to copper or silver as the best metals for fuses. They wanted a metal that had as lean a vapour as possible and as little matter as possible, and most people in these days used copper by preference. But for very small currents it was not possible to get a copper wire small enough to be handled practically, and for this reason metals of more or less higher specific resistance were used. As a filling he had tried a great many substances, but had avoided all forms of sand, glass, or powder, and everything that was at all likely to form, when fused, a conducting liquid. He had tried marble dust and various forms of lime, but finally he had settled down upon a very unscientific material, but one which he had found to be the best, viz., the dust scraped out of the inside of boiler flues. This was a highly infusible material, and it was best when passed through a sieve. He had used that with copper wires in an envelope not too tightly rammed. Reference had also been made to more readily oxidisable metals having tubes formed on them which the authors stated conducted similarly to Nernst filaments. He was certainly in agreement with Mr. Patchell in thinking that these tubes conducted by the molten metal inside. Take, for instance, an aluminium fuse three inches long. When heated carefully at such a temperature, as it would not blow out, it was evident that the inside molten metal was protected by the comparatively thick skin of oxide. The shunting of fuses was also old, and although he did not wish to get up and say, "I did it," nevertheless he had obtained a patent for an enclosed fuse of this character many years ago, and he had often used these fuses. They seemed to work all right. His experience was that the effect of ageing made it very difficult to rate fuses. They might be rated and keep their rating fairly well for a time, but the life of a fuse was a rather unhappy one. It was frequently being heated, and it went through various changes; it was oxidised, expanded and contracted, and he found that with all metals with which he was acquainted the rating changed very much. He thought that this would always be one of the difficulties of rating fuses. One interesting point, perhaps, was that he found that copper wires, when examined under a fairly high magnifying glass—not a microscope—showed, after a long period of use, a multitude of small transverse cracks seeming to go right down into the metal. This reminded him of the fact that at the time Edison was experimenting with platinum lamps, in the early days, he had had to give them up because he found that the life of the platinum filaments was so short, and he had attributed the cause to the gradual growth of these minute transverse cracks in the metal itself. With regard to a magnetic arrangement to help to blow out the fuse he supposed that they had all invented such an arrangement one time or another; in fact, he could give a long list of patents for this particular thing. Perhaps the reason why none of these arrangements had been taken up seriously was the same one which had prompted all of them: namely, that when they found someone else had patented a thing and that it was difficult in consequence to make money out of it, they did not follow it up. A great many people had invented an arrangement of a little spiral inside a porcelain holder or merely a conductor coming up to the fuse itself, arranged spirally, so that the field set up would help to elongate the fuse and blow the arc. It was an interesting arrangement in practice, and he thought it was quite worth while putting the idea into a simple form for house fuses, especially now that higher voltages were being used than formerly. He agreed with Mr. Patchell that for house fuses the best thing was to have plenty of metal; a penny made a very good fuse if they had nothing better.

Mr. A. C. CRAMB, in response to an invitation by the Chairman to speak, said that his experience was generally in accordance with the remarks already made with reference to copper fuses. He was in the fortunate position of hardly ever having his fuses go, and therefore he had no experiences of this kind to relate.

Mr. H. M. SAYERS said he had extensively used copper-wire for street main fuses on secondary networks. He had found copper a most useful and trustworthy material, always provided that it was changed sufficiently often. This he found generally to be twice a year, not at six months intervals, but about the end of August and the end of January, so that the time of heavy load was about fairly divided. Under these conditions copper could be relied upon to blow at a very definite current.

Mr. C. H. WORDINGHAM said that as Chairman of the Sub-Committee of the Engineering Standards Committee which had this question in hand, he would like to acknowledge the great help received from Prof. Schwartz on that committee, and also to thank him for the large amount of help that they were looking forward to having. The thing which had struck the members of the sub-committee most was the extreme difficulty of the problem connected with anything in the nature of standardisation. To begin with, it was difficult to classify fuses. With regard to rating, it was a wonder how very little was known at the present time with regard to fuses, and they arrived at the conclusion that they must get carried out a great deal of experimental work before they could attempt to standardise them. The sub-committee had arranged to divide up fuses into different ranges, and different members of the sub-committee were taking up experiments on these lines. They had laid down a common basis, and had taken steps to secure that the experiments should be carried out on identical lines, so that they hoped when they had standardised fuses their suggested regulations would be founded on experimental data of considerable value. He would like to make one or two remarks on points raised during the discussion. He could not help thinking that those who thought the amount of power behind the fuse had something to do with the matter, and those who thought it had little to do with the matter were really talking about two different things. Prof. Schwartz's experiments all related to a wire between two contacts, which were fixed at what he called "no-arc distance," and he quite agreed that experiments on these lines were necessary as a foundation for any standard conditions for fuses; but the container in which these fuses were carried had a very great deal to do with their action in practice. A good many years ago, when 220 volts were first intro-

Digitized by Google

duced, he made a number of experiments upon existing house-fittings and small fuses to see how they would stand on the higher pressure, and he found that the amount of power behind the short made an enormous difference. At that time he introduced a system of registering fittings, and he had thought that if he tested the fuse at 30, 40, or 50 times the normal fusing current he had sufficiently well imitated a short circuit. Later on he thought it well to repeat the experiment, and he then tried the same fuses by short-circuiting them dead across a large battery, and in many cases he found that those fuses which had passed the first test failed altogether on the second. He had come to the conclusion that if these wires had been supported between two open terminals there would have been no difference, because the oscillograph tests, shown by Prof. Schwartz, indicated that while a certain amount of power in some cases would make no difference the explosive action of the tubes by the sudden development of heat varied very greatly with the amount of power behind. With regard to the rating of fuses, there was certainly a great deal to do and a great deal to consider. The only thing they were all agreed on was that everybody hitherto had rated fuses rather highly. With regard to fillings, he had recently made some experiments to test the amount of caking that might be expected in damp situations. He had taken a large number of tubes and filled them with fine and coarse emery, steatite, fine and coarse sands, chalk, and several others, and had sent them to sea for three months, and then opened them to find if in any case there had been any caking. The result was that there did not appear to be so much caking as many of them would have expected.

Mr. J. J. FASOLA said he was sorry the Paper was confined to low-tension fuses. With the data before them there should not be any difficulty in selecting suitable materials and no-arc lengths for low tension, but he thought they would all be very grateful if the authors could give similar information with regard to high-tension fuses. The conditions in connection with 5,000 and 10,000 volts, for instance, were quite different, and so far there had been a general tendency to resort to the use of oil. He had seen some very large porcelain cartridge-type oil fuses on the Continent about one foot in diameter, but notwithstanding their large size they were not a complete success, and, of course, they were very difficult to handle. They had a fuse wire entirely in air, and arranged so that the lower contact would be drawn under oil at the moment of disruption. The fusing current could be pre-determined fairly accurately, but the metal vapour very often caused sparking over to exposed metal in the neighbourhood. If, on the other hand, the tube was completely immersed, it was conceivable that it was necessary for a film of oil to form about the silver wire before it could blow, and as the conditions of vapour formation and circulation of the oil and thermal conductivity were never the same twice running, it was impossible to depend upon the fuse blowing at predetermined overloads. When the fuse was partly immersed, matters were still worse, because the fusing point depended upon the level of the oil. The best solution of the problem in his opinion was the fuse described by Mr. Patchell in his Paper before the Institution in 1905, and already mentioned by Mr. Patchell in the present discussion.

As time for adjournment had been reached, Prof. Scharwtz was asked to communicate his reply for publication in the *Journal*.

Three written contributions to the discussion have been received:—

Dr. C. C. Garrard (Ferranti, Ltd.) said that the definition of normal fusing current, as given by the method of measurement described in the "Note on Rating Fuses" at the end of the Paper, was no doubt perfectly correct. The time-current curve tends towards an asymptote, and the point where this asymptote cuts the current axis is the normal fusing current. No current below this value, no matter how long it be kept flowing, should blow the fuse. He was under the impression, however, that the authors in their previous Institution Paper on "Low-Tension Thermal Cut-outs" (the I.E.E. *Journal*, March 14th, 1905, p. 364, Vol. 35) had adopted a different definition of "normal fusing current." The oscillograms given in the Paper seemed to show that the so-called "non-arcing" metals of the cadmium or zinc group arced more than any of the others, which confirmed his own opinion, that the so-called "non-arcing" property was more or less a myth. In his experience of fuse testing, the amount of power behind the tests has always been the most important factor determining the severity of the tests. His own tests, however, had generally been with fuses of large sizes (several hundreds of amperes), and had taken place close up to the terminals of the source of supply of current. The most severe conditions seemed to be close up to the terminals of a large battery. He did not agree with the authors' definition of the time element of a fuse, the object of which, he understood, was to arrive at some time element which could be marked on the fuse. The ordinary user, however, seeing the time marked on the fuse, would think that this is the time taken to blow the fuse. He would not realise that it is the time corresponding to some particular current, and that if the current be a little different from the proper current, say 45 per cent. overload, or 55 per cent. overload, the time element would be altogether different. He had had exactly the same experience with inverse time element relays. Of course, the time element of a fuse was also inversely proportional to the extent of the overload, similarly to such relays. It had been at first endeavoured to mark these relays with certain specified numbers of seconds, but it was found extremely difficult to make even electrical engineers understand these markings. The user saw, for example, the relay marked 5 seconds, and assuming the apparatus to be a kind of clock, proceeded to test it with a stop-watch. Generally speaking, no particular regard was paid to the current flowing through the relay, and the result was that the relay was said to be out of order. He had come to the conclusion that the inverse time element of any circuit-breaking apparatus should only be defined in terms of a curve. If the full curve cannot be given, it was better not to mark the time element at all. To illustrate this he took the curves given in Fig. 9, for two fuses of the same normal fusing current. Defining the time element in accordance with the author's definition, that of the free fuse is about four seconds, that of the enclosed fuse about one second. I think now it would be an assumption legitimately made by 99 persons out of 100, that if these two fuses were placed in series with each other, and the same overload current passed through them, the one-second time element fuse should blow before the four-second time element fuse. This, however, did not follow. If the overload was but small, just above the normal fusing current (say 15 per cent.), then the four-second time element fuse would blow before the one-second time element fuse. If, on the other hand, the overload were very large, as, for example, several hundred per cent. above full load, it would be a matter of chance which one would blow first, as if the curves are prolonged the time element disappears altogether in both cases. The matter of time elements of fuses was also of great importance in connection with another subject, viz., to the fuse-shunted trip coils used very greatly at the present day to impart a time element to automatic alternating-current circuit-breakers. Of course, an ordinary trip coil operates practically instantaneously, and the idea is, by shunting the current through the fuse, that the time taken by the fuse to blow will impart the necessary time element to the apparatus. The main object of a time element circuit-breaker was to attain the possibility of having two or more circuit-breakers in series, so arranged that with a definite overload through them they would open in a predetermined order. In the Paper he had submitted to the Institution, but which had not yet been read, he had shown that it is not possible to attain this end by simply altering the size of the fuse wire. Prof. Schwartz and Mr. James' Paper also showed that it is quite impossible to arrive at this end by altering the materials of the fuses or their surroundings. Under conditions of short circuit, therefore, it was impossible to arrange switches in series one with another, controlled by fuse-shunted trip coils such that a discriminating action between the switches would be attained.

Mr. E. B. SCHATTNER gives it as his experience that fibre is the only material which will answer satisfactorily as a casing for enclosed fuses. Neither glass nor porcelain, he says, have the necessary elasticity and strength to withstand the shock of a bad short circuit. An insulated metal tube would, in his opinion, be dangerous. He endorses the remarks made as to the "Nernst effect," and recommends that most, if not every kind, of sand should be avoided as a filling. He has watched sand-filled fuses re-establishing a short circuit after about 60 seconds. Shunted fuses, he found, worked badly on power circuits. The main and shunt fuses fuse at the same instant when sufficient power is behind, and his conclusion is that the essential requirement in a good enclosed fuse is the immediate cooling of the arc and vapours. Both the "Koolark" and the sparklet fuse, he added, work on this principle.

Mr. J. H. M. WAKEFIELD writes:—I recognise that the Paper does not deal with fuses of so low a nominal fusing current as three amperes, but as a considerable number of these are used by the Post Office for protecting telegraph and telephone wires against lighting and power circuits, it may not be considered out of place to put on record that all such fuses outside a building are made of soft drawn platinum wire 5 mils in diameter, connected to copper caps, and enclosed in a glass tube, 3 in. diameter and 2 in. long. Platinoid wire was used in the first instance, but weather effects soon showed that disconnections in the fuses were very frequent, especially after a frost. The effect of contraction and expansion, as mentioned by Mr. Mordey, no doubt applies to a case of this kind. Platinum wire was therefore substituted, and up to the present has been found to meet requirements satisfactorily.

DISCUSSION AT MANCHESTER, MARCH 3RD.

Mr. W. CRAMP, after remarking on the large amount of work which the preparation of the Paper must have involved (for one set of curves alone over 800 experiments had been necessary), said that he was particularly interested in the section on the temperature rise of the jackets of enclosed fuses, upon which very little work had previously been done. Unfortunately, however, it would be difficult for designers to deduce immediately from the results the best form for a fuse intended for any special purpose. He suggested the possibility of attacking the

Digitized by Google

whole subject from a more theoretical point of view. Preece's original fuse formula was derived from the equation :—

$$C^2 = K \frac{JTE}{P} D^3$$

where K is a constant.
D is the diameter of the wire.
C is the fusing current in amps.
J is Joule's equivalent (gramme-calories)
T is the elevation of the temperature of the wire at fusion.
P is the specific resistance of the wire at temperature of fusion.
E is the emissivity in gr. cals. per sec. per deg. at temperature of fusion.

Now Preece introduced inaccuracies by assuming everything constant but C and D, and writing the formula :—

$$C = K_1 D^{\frac{3}{2}}$$

where K_1 is a constant and has a value of about 40 when D is in inches. In 1892 Ayrton and Kilgour (*Phil. Trans.*, R.S. 183A, 1892, p. 371), found the values of E for platinum wires up to 0·014 dia., and pointed out that taking E as constant would make an error of "hundreds per cent." in some cases. Indeed, their curve plotted on a diameter base shows that E varies from 0·002 to 0·005, or more for wires of diameter varying from 14 mils to 3 mils. E. G. Brown showed in 1900 (*Trans., N.Z.Inst.*, Vol 33, p. 364, *et seq*), that tin wires have emissivity values almost similar to these of platinum, and not incompatible with the values well known for steam pipes. What was now wanted was the values of E and K for the following variables: Different metals exposed in air, and also for different metals enclosed, both to be taken with terminals of large and small mass and of various materials. Referring to other points in the Paper, Mr. Cramp contended that no distinction could be drawn between inductive and non-inductive circuits, for the oscillograms showed that, for the purpose of the Paper, the circuit might always be considered as inductive. He estimated that the explosive force of a fuse calculated in the manner shown by Prof. J. J. Thomson for a disruptive discharge, was probably of the order of 600 atmospheres. The terms no magnetic field, lateral magnetic field, and longitudinal magnetic field, referred to in connection with Fig. 2, were, he thought, misleading, inasmuch as with the particular arrangements adopted the distribution of flux would be such as not properly to be characterised by either term. In either case part of the field would be "lateral," part "longitudinal." The results, however attained with the arrangement shown in Fig. 1 were very remarkable. The authors had not called attention to a marked effect visible in curves *A* and *B*, Fig. 5. In virtue of the fact that in *B* there are more turns on the blow-out coil, the blow-out should be much more marked than in *A*. The reverse was the case, however, showing that the inductance added by the blow-out coil more than compensated for the blow-out effect. Finally, Mr. Cramp called attention to a number of enclosed fuse samples which he tested for Prof. Ayrton some years ago, on behalf of the Admiralty. It was found that by far the best enclosed fuse was Siemens & Halske's silver wire embedded in plaster of Paris, which never failed to act. On the other hand, Dorman & Smith's damper procelain holders smashed frequently on short circuit, and on limited overload the "no-arc" fuses were very unsatisfactory, for they would blow and yet still continue to carry almost full-load current with a slightly higher resistance.

Mr. C. F. SMITH took exception to the authors basing their tests on the assumption of a drop in the circuit of 3 per cent. with the normal fusing current of the fuse, as representative of the conditions likely to be met with in house services for mains and distribution fuse-boards He had calculated roughly the value of the self-induction in an ordinary two-wire circuit, and took as an example the case of two parallel conductors separated by a distance equal to ten times the radius of the conductor. On this basis, the self-induction came out at about 0·1 millihenry per 100 yards of circuit. Assuming a length of 100 yards, and taking the rate of fall of the current after its maximum value is reached (from the oscillograms in the Paper) to be 33,000 amps. per sec., the drop in the leads due to self-induction during the blowing of the fuses would appear to be :—

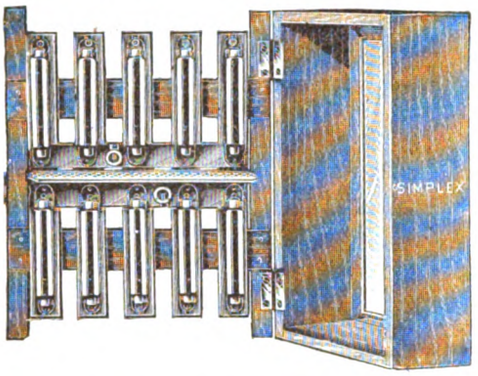
$$\frac{dc}{dt} = \frac{33000 \times 0{\cdot}1}{1000} = 3{\cdot}3 \text{ volts},$$

i.e., the drop in the conductor due to self-induction would be greater than the drop due to resistance. This, however, was not a fair measure of the effect of the circuit inductance, because the value of dc/dt was taken from the authors' curves obtained with a choking coil in the circuit, of which the self-induction was given as 25 millihenries. The rate of fall of the current in a circuit without artificial inductance should be about 250 times as great as that just found, *i.e.*, there ought to be a reverse E.M.F. in the circuit, or breaking, having a value of $3{\cdot}3 \times 250 = 760$ volts. What he wished to emphasise was that an E.M.F. of self-induction of large value compared with the total voltage applied to the circuit would certainly be formed in a circuit which would be termed by the authors "non-inductive." He also pointed out that a circuit having a true self-induction of 25 millihenries would show a very much higher rise in voltage than anything shown on the oscillograms. Doubtless iron saturation and capacity effects in the winding of the coil had actually had a great influence at the moment of fusion, and the value given for the inductance of the coil could not be taken as any guide of the actual inductance of the circuit. On looking at some curves given by Oelschlæger in the *E.T.Z.* for 1904, he found that on a short circuit made as nearly "dead" as possible the value of the rate of change of current was practically 9×10^6 amps. per sec. The reason the effects obtained by the authors appeared to be independent of the capacity of the generators was, in his opinion, the relatively large drop in the circuit compared with the drop due to armature resistance of the generator's armature.

Mr. S. J. WATSON (Borough Electrical Engineer, Bury) said that he had found aluminium of considerable use in connection with feeder and distribution section boxes placed in different parts of Bury. These fuses are about 200 ampere normal carrying capacity, and, even with exceedingly bad short-circuits close up to the boxes, they seemed to cause no trouble and made very little mess. He objected to the semi-enclosed type of fuse, and preferred one entirely sealed up at the ends. In a particular case, a fuse, carrying a normal current of about 100 amperes, on one of the Bury traction boards, was at a distance of some three or four feet from a four-pole changeover switch, the top connections of the switch being for lighting and the lower portions for traction. This fuse blew, and the metal blew across to this changeover switch and caused a short-circuit across the terminals of this switch, and practically shut the machine down, and that was with a tin fuse. The amount of the metal for the 100 amperes was possibly three or four strands of 14 gauge tin, and at that distance it caused an arc to be set up between a difference of potential of about 400 volts. There would be at least 1½ in. distance between the two terminals. Of course, had that fuse been entirely sealed at both ends, such a thing would not have happened. It also had an important bearing on the risk of fire. Another very important point was on the mixture, or the purity, of the tin and the lead. He had at different times had a number of tests carried out on the ordinary tin fuse wire, and found that with a given diameter of wire, supposed to be of exactly the same quality, very different results were obtained. He thought that the makers of wire of that kind should pay a good deal more attention to that point.

Dr. C. C. GARRARD also spoke. His remarks were substantially the same as in the written communication already quoted.

Prof. SCHWARTZ, replying to Mr. Cramp, said that as the Paper dealt with experimental work they had been doing over the last two years for the Engineering Standards Committee, they had purposely avoided making any very definite statements, or drawing up any conclusions, because the matter was in the hands of the Standards Committee. Referring to the use of aluminium, he said that about two years ago some aluminium fuses from section pillars were brought to his notice, which were corroded where the aluminium strip made contact with the copper jaws, owing to the aluminium being highly electro-positive to the copper; this might be reduced by coating the surfaces with blacklead or tinning the contacts. For small circular wires the action of the oxide sheath was prejudicial; it holds up the molten metal until it is vapourised. Aluminium also necessitated a larger mass being used, and this should be avoided. Silver had not been used very largely in this country. Up to about a year ago it was used very largely in Germany, but the Germans had recently congratulated themselves on the discovery that copper was better than silver.



Mr. W. H. N. JAMES said that Mr. Cramp's suggestion that the longer duration of arc with 20 turns as compared with 10 in Fig. 3 was possibly due to the increased inductance obtained, would not hold, as in each case there was extra inductance in the circuit which was large in comparison to that due to the turns round the fuse.

The Berlin Suspended Railway.—The traffic authorities of Berlin, before deciding whether to permit the erection in the east portion of the city of an electric mono-rail suspended railway, required that a short portion of the constructional ironwork of the same should be erected in the narrowest street through which the railway will pass, in order to test the effect on the street traffic and the general effect as regards unsightliness, &c., of the central steel supporting pillars. A portion of the steel construction, about 150 ft. in length, has consequently been put up in the Brunnenstrasse, which has a breadth of only 72 ft., and is described in *Electrische Kraftbetriebe & Bahnen*. Three pillars, each of a different design, have been put up in order that the most suitable design may be chosen. The track and other constructional work supported by the pillars has also been added in order to see if the light is much cut off. The pillars are spaced about 50 ft. apart, and occupy some 10 or 12 sq. ft. each of the road surface. The height of the pillars is about 32 ft., and the total width of the structure at the top some 18 ft. The cars will be suspended from a single rail on either side of the structure, and to ensure the stability of the whole, the central pillars are supported on girders placed crosswise under the street, the girders themselves being supported at each end on concrete foundations. Shorter girders are placed lengthwise under the street, to ensure stability in the other direction. The bottom of a car will be about 20 ft. above the surface of the road.

A NEW FUSEBOARD

THE accompanying illustration shows a new pattern of fuse-board for the ordinary class of house work, which is being put on the market at a very reasonable price by Simplex Conduits, Ltd. The board illustrated is of the five-way pattern. Three different types of fuses can be provided, type A being the ordinary grooved china fuse bridge; type B, a tubular fuse carrier for 15 ampere circuits, and type C, a magazine replacement fuse. The latter allows non-technical persons to easily replace a fuse, and the bobbin on the five-ampere size carries

50 replacements. These fuses are mounted on two battens, and when in position divided by a fillet of asbestos. The case itself is strongly made of teak, with dove-tailed joints throughout, and a glass front. It is not provided with lock and key, but this can be arranged for at a slight extra charge. All the brass connections are of ample size, to give the necessary capacity, and the finish of the whole article is as good as is in keeping with the low price at which it is sold.

The Charing Cross, West End, and City Electricity Supply Company.—In our analysis of the accounts of this company, on page 347 of our last issue, at the bottom of the first column, the words "load factor" were by a clerical error included in the same line as maximum demand, and the figures for the load factor were omitted. These should have been 21·9 per cent. for the West End undertaking, and 19·1 per cent. for the City undertaking.

Glasgow Local Section of the Institution of Electrical Engineers.—We understand from the secretary of the Glasgow Local Section of the Institution of Electrical Engineers that the Paper proposed for reading at the ordinary meeting last Tuesday was not available on that date owing to the inability of the "Papers Editing Committee" to deal with it sufficiently early to allow of timely printing and distribution. In view of these circumstances, the Committee were obliged to postpone the meeting announced in our last issue.

"The Journal."—The February number of the Journal of the Institution of Electrical Engineers, which had just been published, contains the following Papers, with reports of the discussions thereon at the London meetings:—"The Dielectric Strength of Insulating Materials and the Grading of Cables," by A. Russell; "Automatic Cab-Signalling on Locomotives," by J. Pigg. The Inaugural Addresses of the chairmen of five of the local sections are included, and the following Papers discussed before the local sections:—"The Magnetic Testing of Iron," by W. H. F. Murdoch (Leeds); "Further Notes on the Electrical Driving of Textile Factories," by H. W. Wilson (Manchester); "The Torque Conditions in Alternate-Current Motors," by V. A. Fynn (Birmingham). An original communication, by P. H. Powell, on the air-gap correction coefficient, is also published. The next number of the Journal will contain a portrait of the late Lord Kelvin, and a memoir specially written for the Journal by Dr. Silvanus P. Thompson, F.R.S.

The Siemens Engineering Society, Stafford.—An engineering society has been started in connection with the Stafford works of Messrs. Siemens Bros. Dynamo Works, Ltd., under the presidency of Mr. Lee Murray. The following Papers have been read before the society since its inauguration:—December 8th, 1907.—Presidential address. Mr. Lee Murray on "Coal and its Application to the Production of Power Gas." December 2nd, 1907.—"The Siemens-Schuckertwerke Single-phase Commutator Motor," by Mr. Schenkel. December 20th, 1907.—"Commutation Troubles: their Cause and Cure," by Mr. S. P. Smith. January 23rd, 1907.—"The Economical Life of an Electric Lamp," by Mr. H. G. Williams. On Tuesday, March 10th, a lecture will be given under the auspices of the Society, at 8 o'clock, at the Oddfellows' Hall, Stafford, by Professor Gisbert Kapp, on "The Electrification of Railways." All the Papers read before the society, besides being published in the official magazine, *The Electron*, are being published in pamphlet form for the convenience of the members. A conversazione held towards the end of April will conclude the present session.

CATALOGUES AND PAMPHLETS RECEIVED

SINGLE-PHASE MOTORS.—A leaflet from E. Brook, Ltd., of Huddersfield, gives a list of single-phase motors in sizes from ⅛ to 20 h.p., which are in stock for immediate delivery.

SINGLE-PHASE MOTORS.—A leaflet from the Union Electric Co. gives prices of a complete series of single-phase induction motors ranging from ¼ to 60 h.p. for 50, 60, 83, and 100 cycles. Under 1 h.p. they are listed for the squirrel-cage type, and over 30 h.p. in the slip-ring type only, but the intermediate sizes are standardised in both forms. The list is conveniently arranged, and a complete code facilitates ordering.

SWITCHGEAR.—A new catalogue is to hand from Messrs. Parmiter, Hope & Sugden, of Manchester, which gives particulars of this firm's well-known "Ajax" iron-clad switches, knife switches, and a very complete range of iron-clad fuses, distributing boards, and motor starters. Some illustrations of complete main switch boards of the firm's manufacture are given, and appended to the catalogue is a "progress sheet" which illustrates certain new patterns which are on hand at the works, and will be put on the market in a few weeks. These include a new form of enclosed three-pole switch and fuse, in which a separate lid is provided for both the switch and fuses, arranged so that if required they can be interlocked so that they cannot be opened at the same time, and neither can be opened except when the switch is off. Two smaller new patterns of combined ironclad switches and fuses are also shortly to be introduced. We understand that all the standard gap switches, fuses, knife switches, and distribution boards are kept in stock and can be despatched the same day as ordered.

THREE-PHASE MOTORS.—A leaflet from T. W. Broadbent, Ltd., of Huddersfield, contains a specification and price list of three-phase protected type induction motors, in sizes ranging from ¼ to 50 b.h.p. of the squirrel cage type. A series of starters of the auto-transformer type are also included.

Tramways and Light Railways Association.—The March Circular of the Tramways and Light Railways Association states that it has been decided in future to hold annual conferences in various parts of the kingdom. In view of the fact that the Franco-British Exhibition is to be held in London during the current year, it is thought that it might meet the convenience of the out-of-town members if the first Congress were held in London, in connection with such exhibition, and the first week in July has been fixed as a suitable date. A small committee has been formed to arrange details, and full particulars will be published at a later date. Members wishing to read Papers should communicate with the secretary.

A sub-committee of the Tramways and Light Railways Association is engaged upon the preparation of a standard form of accounts, and of a recognised system to be adopted by tramway companies to facilitate the assessment of their property for income-tax purposes. Communications have been carried on for some time past with the authorities at Somerset House, and it has been intimated to the association that in order to give effect to the recommendations contained in their committee's report, the Commissioners must first be satisfied that all tramway companies shall present their accounts in similar form. A standard form is already in use by municipal tramway undertakings, and this committee intend to submit to the various companies a draft form for their approval. Once this matter is settled there is every reason to believe that the Commissioners will favourably consider and give effect to the proposal to include, if not permanent way, at any rate rails and setts, in the term "Plant and Machinery," and that they will also be prepared to entertain proposals in regard to fixed overall rates of allowance for depreciation on the various portions of tramway undertakings. The importance of any such concessions would be of the greatest value, and it is earnestly hoped that all the constituent companies will give their serious consideration to the proposals to be submitted to them by this committee.

Wireless Telegraphy.—The following announcement appeared in the *London Gazette* for Friday:—1. The Wireless Telegraphy Act, 1904, shall apply to British Ships whilst on the high seas Provided that a person on board a British Ship which is registered in any British Possession (other than the Channel Islands and the Isle of Man) or in any British Protectorate shall not be deemed to commit an offence against the Wireless Telegraphy Act, 1904, by reason of the installation or working of wireless telegraphy on such ship if the authority in such Possession or Protectorate having power by law so to do shall have granted a licence for the installation and working of apparatus for wireless telegraphy on that ship and if such person is acting in accordance with the provisions of such licence. 2. The Interpretation Act, 1889, shall apply for the purpose of the interpretation of this Order as it applies for the purpose of the interpretation of an Act of Parliament. 3. This Order shall be published in the *London Gazette* and shall come into operation immediately from and after the expiration of three months after this Order is so published.

ELECTRIC PROPULSION OF SHIPS

MR. HENRY A. MAVOR read a Paper recently on the above subject at a meeting of the Institution of Engineers and Shipbuilders in Scotland.

The use of steam in a turbine, he said, involves essentially a speed of rotation far above what is customary in reciprocating engines. It is not surprising, therefore, that the steam turbine, when applied to marine propulsion, should be materially modified, and that the marine steam turbine is a compromise in which some sacrifice of economy has been made for the sake of avoiding a greater loss due to the characteristics of the propelling apparatus. Within the limits of practice, the efficiency of the steam turbine is increased by increased speed of revolution; while the efficiency of the propeller is decreased by a corresponding change. Fast-running turbines and slow-running propellers are respectively highly efficient instruments, but hitherto there has been no proper method of coupling them together. The underlying principle of the proposals here made is the use of a high-speed turbine running at a uniform velocity for all speeds of the ship, and driving a dynamo from which electric power is taken to a variable speed motor or motors coupled direct to the shafts of propellers of maximum efficiency. The dynamo and motor here occupy an intermediate position, as indeed they do in all cases, between the power and the work, and in effect constitute a gearing which can submit to modifications of its own characteristics, to meet the characteristics on the one hand of the prime mover, and on the other hand of the machinery to be operated.

The author then dealt in a general way with some of the differences in the behaviour of continuous-current and alternating motors, pointing out the inferiority of the latter as regards starting torque. The ordinary multiphase induction motor, he continued, also compares unfavourably with the continuous-current motor in respect of its availability for changes in speed. The continuous-current motor can now be made to give varying speeds through any necessary range without much loss of efficiency, the only consideration being cost. Hitherto the induction motor has not been able to meet this requirement. Where very frequent starting and stopping have to be combined, as they often are, with gradually varying speed, something new must be attempted if the alternating motor is to take the field. The author has been at work on this problem for some years, with the result that he claims to have solved the problem, and that he can meet most of the demands which are likely to arise in practice and deal with some new fields of enterprise which have hitherto for various reasons remained closed to the electrical engineer.

Hitherto the use of electric motors for marine propulsion has been confined to small craft, such as submarines, and one or two small barges and other craft on the Russian rivers and canals. A small electrically operated and propelled dredger has also been constructed in Germany. The motors in these cases are continuous-current machines.

The continuous-current motor, which is so convenient for small applications of power up to 100 horse power, becomes less convenient over this size. Above 1,000 horse power it is not a very practical machine for power purposes where starting and stopping have to be frequently accomplished, and it is not specially suitable for marine work. The multiphase induction motor, on the other hand, has all the properties to be desired in a marine motor except hitherto the facility of speed control. This problem may now be said to be solved.

Some years ago the idea of rotating the outer member of the motor, usually called the stator, occurred to the author, and appeared to offer a solution of the starting difficulty, and this suggestion was made at a meeting of the Institution of Civil Engineers in 1904. The proposal was that the external member should be mounted so as to be free to revolve concentrically with the rotor or armature of the motor. The armature being connected to the load and the outer member being free to rotate, the outer member starts to revolve in a direction opposite to the working direction of the rotor, and having only its own inertia and friction to overcome, it quickly reaches synchronous speed. The motor is now in a position to develop its full load torque with full load current, and all that is necessary is to apply a mechanical or other brake to the external member, bringing it to rest gradually while the rotor starts and accelerates as the outer member or "spinner" comes to rest. The start can thus be made without excessive call for current and without jerk.

This idea soon developed into a proposal to modify the ordinary working speed of the motor by so arranging the external member that it could be driven at any desired speed by gearing interconnecting both members, and an arrangement was worked out and patented for putting this idea into practical shape. It will be seen that by the use of a fast and loose pulley or friction clutch to transmit a part only of the power of the motor the starting can be accomplished with a very small loss of energy. This method, although serving the purpose for which it was designed and giving a useful solution of the difficulty, did not appear to be the final stage. The idea of rotating the outer member and controlling its speed suggested the idea of controlling its motion independently of gearing or other arrangements which involved disadvantageous complications, and a simple apparatus was evolved, which entirely gets over the difficulty of starting, and gives a change of speed in either direction. In this machine the outer member or spinner is made to act as the inner member or rotor of a second motor, the stator of which embraces the spinner. The machine is thus two motors concentrically arranged round the common axis. The three speeds, which may be described as prime, secondary, and tertiary, are attained without loss of efficiency, but if intermediate speeds are desired they are obtained by a slipping brake or external resistance in each case equally with a consequent loss of efficiency. This loss of efficiency is very small, and is less than the loss involved where series wound continuous-current motors are used for speed variations, or intermediate speeds may be obtained by providing a separate supply of current to the external motor and changing its speed by change of periodicity of the supply.

The attainment of three speeds without any loss of efficiency in this class of motor is a very important improvement, because it at once renders it available for such work as steel rolling mills, haulages, hoists, calendering and printing machines, lathes and boring mills, and last, and perhaps the most important of all, driving vehicles either on or off rails, including vessels on the sea.

A proposition to apply electric motors to drive a ship involves primarily a consideration of the conditions with respect to the propeller and the prime mover. Naturally, the propeller with its shaft comes first, as upon its efficiency of transformation of energy depends the size of the prime mover. It is necessary to institute a comparison for any given ship of the normal propeller as used with existing machinery, and see what are the prospects of economy by the substitution of electric transmission for the direct connection between the engine and the screw.

At first sight it does not appear that any economy could be made by the introduction of two successive energy transformations in the dynamo and motor respectively to take the place of a direct transmission.

The maximum possible efficiency of these two transformations with the transmission shaft is not more than about 88 per cent.; while the efficiency of the direct transmission shafting is probably not less than 95 per cent. We thus have a loss of at least 7 per cent. as a primary handicap against the proposal. This consideration may be taken as disposing of the possibility by change of transmission of any economy in ships of moderate size with slow-running propellers of upwards of 70 per cent. efficiency. If electric driving is to be introduced into such ships it must be on other grounds than propeller economy. The case is different when we come to deal with ships in which the power is large and the propellers are run at a high speed. Such cases are becoming common in vessels driven by steam turbines. A very short incursion into the study of propellers is sufficient to show the trend of the conditions which here emerge.

For any given ship, the designer who is at liberty to choose a large propeller for any given power has considerable advantage, as the efficiency may be as high as 70 per cent., and as low as 45 per cent. To say what improvement is possible in any case is by no means an easy matter, because the actual efficiency of any given propeller is often unknown; but the difference in efficiency between the probable bests, when the diameter can be changed, may be found approximately, and it is this which has been attempted. The introduction of electric drive enables one to include in the consideration all speeds of revolution of the propeller, both low and high. The revolutions at which the propeller may be efficiently used are fixed by the diameter and pitch. While, therefore, one may have ascertained what is the possible improvement in efficiency, one must, before claiming the possibility of such improvement, deal with the problem with the limiting diameter of the propeller as a first element in the calculation. It is this consideration which makes any saving in propeller efficiency difficult in high-speed passenger steamers of shallow draught. The difficulty of improving the efficiency of ships of moderate size with slow-running propellers has been shown, so that the most attractive field of enterprise, from the propeller point of view, is in large ships of deep draught and high speed.

If the ship is to be electrically driven, it will probably be found that the most convenient steam prime mover will in all

Digitized by Google

cases be a turbine. The limit of speed of rotation, when the turbine is to be used for driving a dynamo or alternator, is of a different order altogether from the limit of speed imposed upon the turbine by its direct connection to the propeller. In some cases it will be easy to adopt an increase of ten times in the speed of revolution. The turbo-electric generator with its motors compares favourably in economy, cost, and weight with the marine steam turbine directly connected to the propeller shaft, and therefore running at a speed lower than that called for by considerations of steam economy in the turbine. The reversibility and speed variability of the electric motor driven by the turbo-generator run unidirectionally at constant speed dispenses entirely with the objectionable heavy and costly go-astern turbines mounted on the propeller shaft.

The case of a ship which had in the first case a total of 17,000 horse power delivered to the three propellers, and a speed of 20¾ knots, was considered. The propellers were 8 ft. 1½ in. diameter, and the speed of revolutions was 377 per minute. This example was worked out in detail in an appendix to the Paper, and it was shown that the maximum probable efficiency of these propellers was 62 per cent. An electric equipment would permit of the use of propellers of about 14 ft. diameter at 140 revolutions per minute, and an efficiency not less than 70 per cent.—an improvement more than sufficient to cover the loss in the electric motors.

Turning now to the generators, it will be found that the steam turbo-alternator, as used on land in sizes corresponding to those now under discussion, can deliver one electrical horse power to the motors for 12·2 lb. of steam per horse power hour, allowance having been made for all intermediate losses, and for 4 per cent. for driving auxiliaries, no superheat being used, so as to make the comparison with normal marine practice. This figure is startlingly lower than anything which has been touched at sea. It is for full speed and power, but the comparison must also be made at low speeds and powers, and more particularly at the normal working speed of the ship. It will be found that there is certainty of economy in this comparison, again because of the higher speed of revolution of the turbine, which in the electric case runs at the same speed for all powers, while, of course, the direct connected turbine must vary its speed of revolution with the speed of the ship. It is not possible to base any generally conclusive argument on these data, but there is evident encouragement to give detailed study from this standpoint to any particular case which may arise. The same limitation applies to weight and cost. In the example referred to an estimate has been made of the weight, with the result that it appears probable that the decrease in the weight of the steam equipment will more than compensate for the heavy slow-running motors and propellers so that the weight will not be greatly changed. The cost will probably closely follow the weight.

CORRESPONDENCE

THE FUTURE OF THE TELEPHONE SERVICE.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There has recently been much discussion of "the telephone question" at Chamber of Commerce meetings and in the Press, but several of the most important points are lost sight of. Perhaps you will allow me space to state a few broad propositions based on long experience and observation of the working of the telephone service in America, and in the principal countries of Europe.

The telephone service we shall have always with us. It is the quickest, the most direct, and the most perfect means of communication; and it is the cheapest. Since all business depends on communication, and communication is also largely required in social and domestic affairs, the telephone service is certain, if conducted on sound lines, to have an enormous development in this country. In spite of all the difficulties (for a clear view of these difficulties the student of the subject may read *Public Ownership and the Telephone in Great Britain*, by Hugo R. Meyer, Macmillan and Co.), the telephone system of the country doubles itself about every six years. But I hope in my lifetime, and I am not so young as I should like to be, to see at least ten times as many telephones working in the United Kingdom as there are now. Such a development can only be brought about, however, by an enterprising administration, a highly efficient service, and a practical tariff.

The present quarrel of the Chambers of Commerce with the telephone administration is actuated solely by the large user of the telephone service fearing that he is about to lose a bargain—which he thinks the flat rate for unlimited service gives him. This fear drives him to strange statements. The measured rate—payment for service in proportion to service rendered, a principle which is accepted in all other services and all other businesses—is described as "a tax on trade and commerce," and as likely to check the development of the telephone.

To describe a change in the method of charging for telephone service which offers low rates to the majority of users as a "tax on trade and commerce," is manifestly an exaggeration, for the amount spent on local telephone service in the average business establishment is a very small percentage of the total working expenses of that establishment. In the largest concerns, who are the chief opponents of the measured rate principle, the cost of local telephone service is probably only a fraction of one per cent. of the total expenses. So much for the "tax on trade."

But the most vital point, and strangely enough it is one that is largely neglected by both parties to the discussion, is that the measured rate makes for efficiency of service, whereas the flat rate directly encourages the large users to spoil the service for themselves and for others. It is a most difficult thing to make the telephone subscriber realise that he is largely responsible for the general efficiency of the service. Over the actual manipulation of the telephone instrument, over the attention and efficiency with which inquiries and messages by telephone are received and dealt with, and over the facilities provided for handling the telephone traffic flowing in and out of his establishment, the subscriber has full control. It should be clear to every telephone user that the quality of service other users get largely depends upon him. Yet what is one's daily experience? That the telephone is all too frequently left to the office boy or to other junior employees who show a marked disinclination to handle the instrument and the service properly or to deal with inquiries and messages promptly and intelligently. Again, the largest concerns, the very establishments with which prompt communication is most in demand by the business community, are so continuously "engaged," owing to their telephone lines being constantly blocked with outward calls, that one is often obliged to abandon the attempt to communicate with them, after having spent much more time on several ineffective calls than one effective call promptly completed would have occupied. In all large towns there are subscribers who are "engaged" to attempted calls hundreds of times daily—to the exasperation of their correspondents, and to the general detriment of the service; in many cases, also, the lost call must mean loss of business to the firm for which it was intended.

Now, what is really the prime requirement of the business man—the essence of "the telephone question" from a practical and commercial point of view? I say unhesitatingly it is efficient service—the maximum of effective calls, promptly and effectively dealt with at the incoming end. There is no difficulty to-day in equipping and organising a telephone service so that the average call shall be put through within 30 seconds. But it is essential for real efficiency that the subscriber on his part shall provide facilities for receiving the call and organised attention for handling it effectively. This the measured rate tariff directly encourages him to do, whereas the flat rate tariff operates in exactly the opposite way. Under flat rates the charge for extra lines is relatively high, so the subscriber refuses to take them. The measured rate tariff makes low charges for lines and instruments, and low wholesale rates for calls. The large user is thus encouraged to provide, instead of one or two individual lines and telephones, a group of lines and telephones, made interchangeable by means of a switchboard. This arrangement, technically known as a "private branch exchange," is extremely flexible. It can be designed to fit any establishment. Every department has its telephone, and every call goes straight to its billet with the minimum of delay. As the lines are worked in a group it is seldom that all are "engaged" simultaneously, and by watching the traffic the equipment can be so kept up to the requirements that the "engaged" call is eliminated. Thus, the big user gets a thoroughly effective service, which is what he needs far more acutely than an apparently cheap rate—for a rate which causes inefficient service is only apparently cheap. I venture to say that the large user has no real conception of what adequate telephone service means until he organises his telephone equipment on the "private branch exchange" basis.

What the measured rate principle will do for the development of the telephone in Great Britain and for the efficiency of the service is amply demonstrated by results in America. Thirteen years ago there were in Greater New York about 18,000 telephones under flat rates, and development was almost stagnant. Measured rates were introduced and the private branch exchange scheme was devised to provide adequate service for large users. To-day there are over 300,000 telephones in New York. A third of those are connected to private branch exchanges, and the ineffective call, which was formerly as great an evil in New York as it is in English cities to-day, has been nearly wiped out. The telephone in New York, besides being used in an efficient way by the large concern, has spread to all sorts of small establishments and to a very large proportion of private residences—for the measured rate tariff makes equitable terms to all classes of telephone users.

Did the Chambers of Commerce but thoroughly study the subject and realise that the measured rate principle of telephone tariff makes both for general efficiency of service and for wide development of the telephone, they would undoubtedly petition the telephone authorities to abolish the flat rate forthwith instead of arguing for its retention. I am, &c.,

REVIEWS OF BOOKS

Thomas Alva Edison: Sixty Years of an Inventor's Life. By F. A. Jones. 375 pp. 7¾ in. by 5½ in. Several illustrations. (London: Hodder & Stoughton.) 6s.

More exaggerated statements have appeared in the less responsible sections of the Press about Edison than about any other man living, so that many readers will take up a book such as this with the hope of seeing the great man depicted as he is, and not as he is imagined to be, as well as to get some idea of the relative place of his work in the development of electrical engineering amongst that of others. It would be unkind to say that the reader will be disappointed in these respects, for not only is there much evidence of authenticity in the writer's statements, but there is a pleasant feeling all through that the pages are written by one who knows and understands as a friend the man about whom he is writing. As to Edison's life work, however, the author is at a disadvantage, for an account of the inventor's work of much more interest could have been written by one whose technical knowledge enabled him better to understand the inventor's aims and objects. The general impression apt to be caused is that Edison was the one and only worker in the subjects to which he devoted his activities, and an untechnical reader will lay down the volume with a hazy notion that Edison originated, rather than perfected, the quadruplex system of telegraphy, that he alone "invented" the microphone, and that no one else succeeded in producing a practicable incandescent lamp. It might also almost be inferred that the versatile experimenter was, at the time of the equipment of the first Edison supply station, the only dynamo builder in the world. It must not be thought that we wish in any way to belittle Edison's work. There is not one of the many subjects that came into his hands that he has not left his mark upon, and it is difficult to realise how many industries in the United States are the direct outcome of his persistent endeavours.

We have not space to recapitulate the many branches of Edison's work through which the author leads us. An interesting account is given of his boyhood and youth as newsboy and telegraph operator, and his experimental work on telegraphy, telephony, the incandescent lamp, the phonograph, and other subjects, and of particular fascination is the story of the establishment of the first Edison supply station in New York.

Edison's greatness seems to lie as much in his extraordinary perseverance and his almost unparalleled capacity for long and continuous work as in his remarkable ingenuity and powers of perception. He has never posed as a man of science or a mathematician; indeed, to use his own words, referring to mathematicians, he "soon found he could guess a good deal closer than they could figure," so he went on guessing. His perseverance is shown by the fact that in the search for a suitable material for lamp filaments, he experimented on about 6,000 specimens of different kinds of bamboo, and only found three species which gave good results.

We naturally turn to the chapter on the storage battery for information as to how much of the obviously exaggerated statements made about the principal object of Edison's latest work is true, but we soon find that the author knows little more about the matter than ourselves, as is shown by the following quotation:—"It will be readily understood that in the manufacture of a perfect storage battery, one of the hardest nuts to crack was the invention of an ideal accumulator or condenser—that portion of the battery capable of containing large quantities of electricity." Again, in one place it is definitely stated that cobalt is used in the latest form of the battery, although further on the active material is spoken of as nickel. The usual extravagant claims are made as to its suitability for automobile work. Two facts, however, are significant, first, that so little is known about the battery, which quite accords with Edison's characteristic of not allowing information to leak out until he sees success in sight, and secondly, the fact that large factories are being put up for its manufacture, a thing which a man of Edison's great business ability would not permit unless the experimental stages were passed.

Universal Electrical Directory (J. A. Berly's), 1908. Pp. 1508, 10 in. by 6 in. (London: H. Alabaster, Gatehouse, and Co.) Price 14s.

No special alterations have been made in the arrangement of this indispensable work, which makes its appearance for the 26th time, but this may be taken as sufficient testimony to the degree of perfection which the compilation and arrangement of the contents has reached. There are still the four sections, viz., British, Colonial and General, Continental, and U.S.A., and, despite the elimination of unimportant entries, the total number of names now exceeds 35,000. Lists of all electricity undertakings in the United Kingdom, British Colonies, and some other countries are given, showing the nature of the supply, system of distribution, capacity of plant, voltage, and chief engineers' names, and in the case of alternating current the phase and periodicity also appear.

Local Government Board Annual and Official Directory for 1908. Pp. 282, 7 in. by 5 in. (London: "Local Government Journal" Office.) Price 1s. 6d.

The seventeenth edition of this valuable work to all interested in municipal affairs has been published; it contains information regarding municipal electric supply undertakings in the metropolis.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

The *Times Engineering Supplement* recently contained an interesting article upon "Bullion Refining by Aid of Electricity." As is well known, large quantities of gold and silver are obtained from the slimes produced in the electrolytic refining of copper, and it is estimated that in the United States alone at least £3,500,000 worth of these metals is annually obtained. In the deposition of the copper, the conditions are such that the gold is precipitated in the metallic form, and the silver is produced as the sparingly soluble sulphate, and through an addition of a small quantity of sodium chloride to the bath as the insoluble chloride. The first attempt to electrolytically fine bullion appears to have been made in 1881 by the Norddeutsche Affinerie at Hamburg, the method employed being that of Wohlwill, but exactly what it consists in is kept secret. By the refining of silver containing lead, they are said to produce more than 100,000 kilos. of silver per annum.

The Moebius cell, patented in 1885, and first worked in Kansas in 1886, is largely employed in the copper refining districts, although the refining is often done by ordinary metallurgical methods. It would appear, however, that gradually the metallurgical parting processes are being superseded by the purely electrochemical. The advantages of electrical refining are (1) greater simplicity, (2) greater cleanliness, and (3) reduced losses. The main disadvantage is the large amount of metal locked up, upon the value of which interest charges have to be met.

The silver to be refined is usually refined metallurgically to 950 fine, and this is employed as anode material in a bath containing silver nitrate and a little nitric acid or sulphuric acid and nitre. As the anode goes into solution, considerable slimes are produced, and, to prevent these falling into the bath and contaminating it, the anodes are enclosed in linen bags. The cathodes consist of thin sheets of pure silver. The silver is deposited in a crystalline form on the cathode, and the slimes containing gold remain in the linen bags. If the silver being refined contains much copper, there is a danger of the copper being deposited out, especially if the voltage used is at all high. In some cases where the bullion employed is very rich in copper, the anode solution is caused to flow into a receptacle containing strips of copper. This causes the copper to react with the silver solution and silver to be deposited,

$$2AgNO_3 + Cu = 2Ag + Cu(NO_3)_2.$$

In such a case the cathodes are of copper, and copper is the metal deposited out electrolytically. Several types of Moebius cell are employed, the older ones being very similar to copper depositing vats. More recently, however, the cathode has been made of a revolving band of silver, the anodes being placed above it in shallow porous porcelain troughs. As the band travels to the end of the bath, it meets another band which works outside the bath and carries off the crystals of silver from the cathode. This in turn passes against a scraper, which effectually removes all the crystals, and causes them to fall into a receptacle placed outside the vat.

A plant at Perth, Amboy, owned by Guggenheim Bros., is worked on this principal. It consists of 48 vats, each 14 ft. by 16 ft. by 7 ft. deep. The electric plant produces 220 amperes at 90 volts, and is capable of depositing 24,000 oz. per day. The American Smelting & Refining Co. also operates a similar plant. This installation has 144 vats, and the electrical generating plant has a capacity of 62 kw.

Gold in silver bullion containing only 2·10 parts of gold per 1,000 of bullion can be recovered by the Moebius process, the cost of separation being stated to be 0·062d. per oz. of bullion. The silver produced tests 999·5 to 1,000. In Europe the most important installation of this process is that of the Deutsche Gold und Silber-Scheide-Anstalt at Frankfurt.

The Balbach Smelting & Refining Co., of Newark, U.S.A., employ a vat which differs considerably from the Moebius vat. The anodes are cast into thin slabs, and are encased in cloth. They are then placed in a wooden frame, which hangs just

Digitized by Google

below the surface of the electrolyte. The cathodes consist of slabs of Acheson graphite, which cover the floor of the vats, and have an effective surface of eight square feet. A current density of 20 to 25 amperes per square foot of cathode surface is employed, the E.M.F. being 3·8 volts to each vat. The silver is deposited in the crystalline condition, and is removed from time to time. The current efficiency is said to be 93 per cent. The chief disadvantage in the electrolytic deposition of silver is the crystalline form in which it is deposited. Easterbrooks claims to have overcome the difficulty by using gelatine in the electrolyte, and by an improved method of circulation. Under these conditions, a smooth, coherent deposit of silver is said to be formed with a current density of 10 amperes per square foot.

For the refining of gold there appears to be only one method – that of Dr. E. Wohlwill, the chemist to the Nord-Deutsche Affinerie, at Hamburg. The process is in operation at Frankfurt, Hamburg, Paris, New York, Philadelphia, and San Francisco. It is shortly to be introduced into one of the principal London refineries. In this process the impure gold anode, 1/6 in. thick, containing 15 per cent. of silver, is placed in a cell containing an acidified solution of gold chloride, thin sheets of pure gold being used as cathodes. The electrolyte contains from 25 to 30 grams of chloride of gold, and 40 c.c. of strong hydrochloric acid per litre. During electrolysis the temperature of the bath is kept at 65° C.

In 24 hours 80 per cent. of the gold will be dissolved and redeposited at the cathode. Another 10 per cent. will be found mixed with silver chloride in the anode slimes, and 10 per cent. will hang together as anode. The anode and cathode are placed 1·25 in. apart, and the gold is deposited in a crystalline condition. Small quantities of platinum and paladium are usually present in the anode, and these are recovered by chemical treatment of the electrolyte. One important point is the very small amount of space which the plant takes up. The vats at Hamburg are sufficient to produce 75 kilos. pure gold in 24 hours, but they only cover a space of 24 sq. ft. The Wohlwill method is also worked at the United States Mint in Philadelphia, where seven cells are in use, capable of producing 5,000 oz. fine gold per week.

ELECTRICAL SCIENCE

British and American

Electric Discharges through Gases.—On Saturday last, at the Royal Institution, Prof. J. J. Thomson delivered the first of a course of six lectures on electric discharges through gases. The lecturer said that he would deal first of all with the most inconspicuous and only recently investigated branch of the subject, that is, the discharge of electricity through the atmosphere at ordinary temperatures and pressures. Coulomb had attributed the loss of charge, which took place when a charged body was suspended in the air, to the conductivity of the air; but this fact was not accepted until after Prof. Boys' experiments, with electroscopes with quartz-fibre suspension and supporting pillars of various lengths. This loss of charge has been found to be proportional to the volume of gas surrounding the charged body, and also proportional to the mass of the gas, except in the case of hydrogen. The loss of charge or the conductivity of the air was due to the charged particles in the air. To demonstrate the existence of these charged particles, Prof. Thomson showed an experiment in which a volume of dust-free air was suddenly expanded; the moisture in the resultant supersaturated air was deposited in the form of a cloud, the charged particles forming the nuclei for the drops of water. There were, he said, normally some 1,000 of these particles per cubic cm. of air. If a little radium were brought near the vessel containing the supersaturated air, the condensation was more complete, as the presence of the radium increased the number of charged particles in the air. It was found by experiment that the rate at which a charged body lost its charge was decreased 30 to 40 per cent. if the body was enclosed in a thick lead vessel, also that the rate at which a body exposed to the atmosphere lost its charge varied from day to day. A series of observations made by Mr. Dykes showed that the fluctuations in the rate at which some electroscopes lost their charge corresponded with the fluctuations in the amount of radium emanation present in the atmosphere. Thus the conductivity of the air is due to and is a measure of the amount of radium emanation in the air. Prof. Thomson showed a table in which the amount of radium in rocks of various kinds was given. This amount varied from 5×10^{-12} grams per gram for oolite to less than 1×10^{-12} grams per gram for chalk. In close connection with this was the amount of emanation present in the air. Sea-water was peculiarly free from traces of radium, and it would be interesting to have some figures for the conductivity of air in mid-Atlantic. It might be asked, Prof. Thomson added, how the earth could retain its charge of negative electricity if the air conducts? If there were not some means of re-charging the earth, the charge would be lost in an hour. A few hundred amperes would suffice for the whole of the surface of the earth, but the difference of potential amounted to several millions of volts. In Prof. Thomson's own opinion, this re-charging was effected by rain as follows:—With a drop of temperature, the moisture in the air condenses with dust particles for the nuclei of the drops, and thus the air is being continually filtered from dust particles until at the higher altitudes the air is dust-free, and condensation with the negative particles as nuclei takes place. The drops of rain from the higher altitudes have therefore a charge of negative electricity. Only recently has it been definitely proved that drops of rain are negatively electrified. These drops fall at a slower speed than non electrified drops, as they have to be drawn to the earth by gravity against the potential of the earth. The charge thus brought down by rain is spread all over the surface of the earth and the charge thus continually renewed. With regard to the theory that the negative charge of the earth was renewed by a bombardment of negative particles from the sun, Prof. Thomson said that in his opinion the particles would not arrive with sufficient energy to enable them to overcome the difference of potential existing between the outer layers of the atmosphere and the earth's surface.

Continental

A New Kind of Rays.—The well-known Italian physicist, Augusto Righi, announces, in the *Rendiconti dei Lincei* for February 2nd, that he has discovered a new kind of radiation consisting of what he terms "magnetic rays." It consists of a projection of molecular magnets from the cathode when immersed in a strong magnetic field. The molecular magnets follow the magnetic lines of force, and trace them out visibly. That cathode rays are projected along the magnetic lines of force when the field is very strong was proved as long ago as 1858, by Plücker, and Villard studied this phenomenon in detail two years ago. Now a cathode particle or electron, projected along a magnetic line of force, describes a spiral whose generating circle is the smaller the stronger the field. The axis of the spiral coincides with the magnetic lines of force, and when the generating circle is very small, the path of the cathode particle cannot be distinguished from the line of force. But these magnetic rays do not, as a rule, convey a charge. Righi concludes that they really consist of binary systems, an electron revolving round a positive atom, with the plane of its orbit normal to the direction of propagation. Such a system would constitute a very flexible molecular solenoid, and would have considerable stability. A divergent field would produce a retardation of the system, and eventually a return to the cathode.

Dispersion in Interstellar Space.—An important discovery appears to have been made by C. Nordmann. It has hitherto been considered as certain that light of all wave-lengths is propagated with the same speed through the ether, whatever may happen in ordinary matter. An obvious instance of this is the disappearance and reappearance of Jupiter's satellites, which should be coloured if interstellar dispersion existed. But if Jupiter were removed a million times further, some perceptible difference might arise. Now the author has practically obtained such conditions in the case of Algol and λ Tauri. These are both "occultation binaries." The method, which is described in the *Comptes rendus* for February 24th, consisted in obtaining monochromatic colour curves for these two stars, and looking for any lag of one curve behind the curve of another colour. Such a lag was actually observed. In Algol red light was 16 minutes ahead of blue light, and in λ Tauri this difference amounted to a whole hour. If the dispersion is the same in all space, it means that λ Tauri is three or four times as far away as Algol. In any case, the lag of the blue behind the red does not exceed one part in two million.

Electrolytic detectors.—In the Ferrié electrolytic detector a very fine platinum point is immersed in sulphuric acid, and the opposite electrode has a large surface. The impinging wave, gathered up by the antenna, is brought to a high potential by a suitable transformer. The detector is contained in the secondary circuit, together with a condenser adjusted to resonance. The platinum point is permanently charged to a positive potential closely approaching the point of electrolysis, by means of an auxiliary battery, and the telephone is placed in the polarising circuit. If this circuit has a low resistance, the degree of syntony obtainable is very high. Ordinarily, the resistance is several thousand ohms, but it may be reduced by heating the detector to 120° C. It then falls to a few hundred ohms. At the same time, the capacity increases from a hundredth of a microfarad to 0·5 mf., but this has no perceptible effect upon the sensitiveness, and is easily compensated. As regards the mode of action of the detector, it appears that the positive limb of the primary current curve increases the polarisation and the current in the secondary, but the energy required for this increase is furnished by the oscillatory circuit itself. A detailed study of these processes is contributed by H. Abraham to the *Comptes rendus* for February 24th.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 5th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.
Names in brackets indicate communicators of inventions from abroad.

1907 Patents

3,982, S. O. COWPER-COLES. Vessels for containing fused salts during electrolysis. As only some liquid metals, such as tin, lead, or mercury, can withstand the action of the fused salts, the inner retaining vessel is formed by such a liquid. The outer vessel, which is heated externally, is constructed of iron, or other suitable conducting material, and is spherical or parabolical in shape. This vessel is rotated at a sufficiently high speed to cause the liquid metal within it to distribute itself by centrifugal force over the inner surface. There is a continuous flow of the liquid metal through the apparatus, and the reduced metal is carried away wth the said liquid metal. A carbon electrode is introduced into the vessel from above, and the vessel itself forms the other electrode. Four claims, two figures.

4,152, J. S. PECK. An arrangement for equalising the load on alternating-current systems, and for supplying slow speed induction motors with low-frequency currents from high-frequency circuits. The stator winding of the induction motor of a motor-converter set is connected to the supply mains, the rotor winding being connected across to the suitable points on the armature winding of the direct-current generator. This generator has a shunt field system of the usual type, and the current generated is supplied to a direct-current motor coupled to a flywheel. The working motor is fed with current taken off by means of slip-rings connected to the cross-connections between the two rotors of the motor-converter set. The working motor thus normally receives its current direct from the rotor of the induction motor, and in cases of overload, also from the armature of the direct-current machine, which acts as a rotary-converter, taking in current from the flywheel motor, which then acts as a generator, and converting it to alternating current for driving the working induction motor. When the induction motor is not working, the converter set supplies power to the flywheel motor, accelerating and storing up energy in the flywheel. One claim, one figure.

7,048, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) Wedges for retaining armature conductors in slots, particularly in the case of induction motors, where the surface of the iron core should be, as nearly as possible, an unbroken area of magnetic material. The wedges can consist either of a series of longitudinal or transverse strips of magnetic material connected together, but electrically insulated from one another. For instance, a pile consisting of alternate strips of iron and fibre, riveted together; or, again, they can be moulded in a material consisting of iron-filings or iron-wool, and a suitable binding material, as sodium silicate. In the latter case a backing of some strong fibrous material is provided to strengthen the magnetic wedge. Five claims, four figures.

9,572, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*). A method of fusing metallic filaments to the leading in or supporting wires. The welding of the wire to the filament is performed by means of an electric arc, in a protecting jet of some reducing gas, such as hydrogen, surrounded by an envelope of an inert gas, such as carbon dioxide. A special nozzle for the gas jet is described. Five claims, four figures.

10,861, FRANKLIN PUNGA. A multiple circuit multiple winding for direct-current armatures. Equalising connections between the different individual windings are provided, so that the potential of each commutator segment is as nearly as possible mid-way between the potentials of the two adjacent segments. (A description and a diagram of this winding will be found in ELECTRICAL ENGINEERING Vol. II., page 884). Two claims, three figures.

14,955. T. TORDA & L. TORDA. An arrangement of boosters in multiple wire distribution circuits. Each booster is provided with two series windings, one in series with the outer wire, with which, also, the armature is in series, and one in series with the neutral or inner wire. These windings are so arranged that if the two windings of one booster are assisting each other, the windings of the other booster are opposing each other. As a result, the pressure between the inner and the two outer conductors remains constant with unbalanced and varying load. Three claims, two figures.

24,751, SIEMENS-SCHUCKERTWERKE GES. Means of artificially cooling commutators of high-speed machines. The cooling medium, for instance, oil, is fed or pumped in through a central inlet passage in the shaft, and is discharged out of this passage through radial ducts in the shaft on to the inside surface of the commutator segments. It leaves the commutator at the same end as that at which it enters. Four claims, two figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.
Summaries of the more important of these patents will appear in our next issue.

1906 Patents

28,600, BECK & DEUTSCHE BECK-BOGENLAMPEN GES. Arc lamps.
28,601, BECK & DEUTSCHE BECK-BOGENLAMPEN GES. Arc lamps.
28,638, GIN. Induction furnaces.

1907 Patents

3,783, LEVY. Wireless Telegraphy.
3,962, RICHMOND. Electric batteries.
3,981, COWPER-COLES. Zinc and aluminium alloys.
4,026, VOSMAER. Resistance coils for rheostats.
4,031, FYNN. Alternate current motors.
4,085, COLEMAN. Electric alarm apparatus.
4,137, CABOT. Wireless signalling systems.
4,181, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) Prevention of electrolysis.
4,211, CROMPTON & CO., MACFARLANE, & BURGE. Rotary transformers and motor generators.
4,593, MARCONI & MARCONI'S WIRELESS TELEGRAPH CO. Transmitting apparatus.
4,832, CHRISTENSEN. Voltaic cells.
5,100, CÔTE & PIERRON. Electric furnace.
5,506, LAMME. Alternating-current commutator machines.
6,289, WALTER. Methods of electrical control.
7,180, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) Electrical resistances.
8,984, HOOKHAM & HOLDEN. Electricity meter.
9,591, GROSS. Supports for arc lamp carbons.
9,923, ROBERTS. Electric switching mechanism.
11,177, HADDAN (*Polyphos Elektrizitäts-Ges.*). Röntgen ray apparatus.
13,072, WHITE. Electric controllers.
13,195, BRITISH THOMSON-HOUSTON CO. (*Allgemeine Electricitäts Ges.*) Railway signalling systems.
16,087, MACKENZIE (*Lorenz*). Telephone alarm.
16,952, KJELLBERG. Electric welding or soldering.
20,201, SIEMENS BROS. DYNAMO WORKS, LTD., & HOLMES. Searchlight projectors.
20,949, SIEMENS BROS. DYNAMO WORKS, LTD. (*Siemens Schuckertwerke Ges.*) Control of electric vehicles.
23,317, HARTMANN & BRAUN AKT.-GES. Frequency indicators.
24,288, BOSCH. Contact breakers for electrical ignition.
24,874, RICHARDSON. Electric conductors.
25,118, ARCIONI. Alternating current thermal wattmeters.

Complete Specifications open to Public Inspection before Acceptance.

1908 Patents

3,056, STRUBLE. Relays.
3,251, IVERSEN. Regulation of hoisting plants.
3,242, GROUVELLE, ARQUEMBOURG, & JORET. Use of the motors of automobiles as brakes.
3,283, ALLGEMEINE ELEKTRICITÄTS-GES. Arc lamps.
3,285. ALLGEMEINE ELEKTRICITÄTS-GES. Rock-drills.
3,401, JENNEY. Automatic switches.
3,464. ANDERSSON. Electric arc lamp.
3,465. ANDERSSON. Carbon holder for arc lamps.
3,492. MÄHL. Meters.
3,505. MERTENS. Current-collector for electric cars.

Expiring Patents

The following Patents expire during the current week, after a life of fourteen years:—

5,508, of March 16th, 1894. ALEXANDER MUIRHEAD. Improvements in the apparatus for automatic transmission on submarine cable circuits. The improvements consist in a special shaping of the contact-making levers, and in the employment of grooved rollers mounted on the same axis as the spur-wheel, for controlling the movement of the levers. Six claims, eleven figures.

5,651, of March 17th, 1894. E. J. PRESTON & A. B. GILL. A method of suspending a belt-driven train-lighting dynamo. The tension in the belt is such that after a certain predetermined speed has been attained, the belt slips and no further increase in the speed of the dynamo takes place. Also, a rocking switch, mounted freely on the dynamo shaft, which reverses the direction of the current when the direction of rotation of the dynamo is reversed. The switch is controlled by a governor, which causes it to be closed as soon as a certain speed is reached. Six claims, nine figures.

LOCAL NOTES

ABERDEEN: *Electricity Supply in Cults.*—A report has been received from the Electrical Engineer, giving two schemes to cope with the immediate wants of the Cults district. The first one involves the transmission of high-tension current to a sub-station, where it will be transformed to low pressure at an expenditure of £2,724. The second scheme provides for the laying of three high-tension cables instead of one as far as the city boundary, with a view to providing for the increasing demand within the city. This, the Engineer estimates, would cost £6,660. The Electricity Committee recommend that the second scheme be adopted.

Supply to Suburban Tramway Co.—A letter has been received from the secretary of the Aberdeen Suburban Tramways Co. asking what terms the Council will propose in the event of the company requiring a supply of electrical energy for their undertaking, after the expiration of the present agreement, which will shortly terminate. It may be pointed out that for some time past the Tramways Company have openly stated their opinion that the present rate is too prohibitive for them to continue, and the erection of their own power station has been hinted at.

ABERSYCHAN: *Order Revoked.*—The Board of Trade have revoked the Electric Lighting Order of 1905, as from February 25th, 1908, regarding the whole area of supply.

ACCRINGTON: *Power Supply.*—It is stated that the contract which the Corporation have just renewed for the supply of electricity to Messrs. Howard & Bullough for another five years represents the largest supply given by any municipality in the county to a single business concern.

AVONMOUTH: *Supply from Bristol.*—The laying of the feeder cable, by which the supply to the Avonmouth dock is to be obtained from the Bristol Corporation station, is being carried out by Messrs. Siemens Bros. & Co. The transmission pressure is 6,600 volts, and the cable is lead-covered and laid in stoneware troughs filled with bitumen. Transformers at the docks will reduce the pressure to 250 volts in the case of the old dock and 600 volts in the case of the new dock.

BARROW: *Electricity Charges.*—A letter has been received from the Barrow-in-Furness Traders' Association, asking the Electricity Committee to appoint a sub-committee to meet a similar sub-committee of the association to discuss the question of electricity charges. The Electricity Committee has refused to accede to this request, but the association has been informed that the chairman of the committee and the Borough Electrical Engineer will be pleased to meet members of the association at the electricity works for an informal discussion of the whole question.

BIRMINGHAM: *Expenditure on Tramway Cables.*—At the meeting on Wednesday last week, the chairman of the Tramways Committee moved that the sum of £12,293 expended in laying cables, and £1,021, the cost of laying the cables for the Aston tramway route, should be assigned, under the provisions of the Birmingham Corporation Act, 1905, to the electric lighting undertaking. The resolution was carried.

BOLTON: *Tramways Parcel Traffic.*—After much discussion the Bolton Town Council have finally decided to inaugurate an elaborate system of parcel carrying by tramcar, in accordance with terms and conditions arranged with the Bolton Combined Tramways Association.

BRIDLINGTON: *Revised Tariff.*—The Electricity Committee have resolved that the price to consumers of from 500 to 749 units per quarter be at the rate of 4½d. per unit, and to consumers of 750 units and upwards per quarter, 4d. per unit.

BRIGHOUSE: *Breakdown.*—A rather serious breakage occurred last week to one of the gas engines at the electricity works, when the piston and a portion of the cylinder were hurled a considerable distance, owing to the bursting of the latter. No one was injured. There is considerable trouble in maintaining the supply.

BRIGHTON: *Electric Omnibuses.*—At the meeting of the Corporation on Thursday, the Watch Committee reported that the Brighton, Hove & Preston United Omnibus Co., and a Mr. Thornton, representing a London company, had written regarding the substitution of electric omnibuses for some of the seven petrol omnibuses now in use in the first case, and for the introduction of a new service in the second case. The committee had replied to Mr. Thornton that, provided such electric omnibuses were approved by the committee and the Chief Constable, no objection would be made, on the understanding that he agreed to run a service of electric omnibuses from Preston Circus to the northern boundary of the borough. An amendment was moved to omit the portion of the minutes relating to Mr. Thornton's application on the ground that it showed favouritism and was detrimental to the interests of the existing company. After some discussion this was carried by 25 votes to 23.

BUENOS AIRES: *Underground Electric Railways.*—H.M. Consul reports that since the proposal made last year to construct electric tube railways in Buenos Aires, both the Mayor and Municipal Council have been changed, and it is impossible to say with any degree of certainty whether or when the work will be carried out.

BURNLEY: *Electricity Statistics.*—The annual financial report of the Burnley Corporation, just issued, shows profits on the electricity undertaking of about £6,000. For the coming year the profits are estimated at £4,900, the chief reasons being an extraordinary increase in the assessment of the department from £1,300 to £4,000. In the tramways department there is a balance of £10,000, which it is proposed to place to depreciation and reserve—the largest surplus the department has reported.

New Tramcars.—The Council has referred back for further consideration a resolution by the Tramways Committee, relating to the purchase of five tramcars at an estimated cost of £800 each.

CALCUTTA: *Electricity Supply.*—The increase in the business of the Calcutta Electric Supply Corporation is shown by the fact that the number of units delivered to consumers during the five weeks ended January 31st was 401,412, compared with 366,569 units in the corresponding five weeks of 1907.

CARLISLE: *Electricity Employees Dinner.*—The fifth annual dinner of the employees of the Corporation Electricity Works was held on Friday. In proposing "The Carlisle Electricity Undertaking," the chairman, Mr. C. D. Burnet, Chief Electrical Engineer, stated that for the eleven weeks ended February 15th, 1908, 29,850 additional units had been sold, compared with the same period of 1907, but the revenue was less by £170.

CEYLON: *Import Tariff.*—A notice has been issued that electric motors shall in future be admitted into Ceylon free of duty.

CHELMSFORD: *Street Lighting.*—The Electric Supply Corporation and the Chelmsford Gas Co. are to quote in competition for the erection, lighting, cleaning, and maintenance of certain additional street lamps which are required.

DOVER: *Supply to Admiralty Harbour.*—The following particulars of the scheme in accordance with which the Electricity Department propose to supply electricity to the Admiralty Harbour have been approved by the Corporation:—The charge for lighting to be 2⅞d. per unit up to 200,000 units per annum, with a guaranteed minimum annual consumption of 100,000 units; units in excess of 200,000 per annum to be charged at 2⅜d. The maximum demand for lighting not to exceed 100 kw. in event of this demand being exceeded, the 2⅞d. rate shall be payable on an additional 10,000 units beyond the 200,000 units for each additional 10 kw. demanded, and the guaranteed minimum annual consumption shall be increased by 100,000 units for each additional 10 kw. demanded. The power rate proposed is 2¼d. per unit up to 200,000 per annum, with a minimum of 100,000 units, 2d. per unit up to 300,000 units, and 1¾d. beyond. If the maximum power demand exceed 250 kw., the 2¼d. rate shall be payable on an additional 8,000 units beyond the 200,000 units per annum for each additional 10 kw. demanded, and the guaranteed minimum shall be increased by 4,000 units for each additional 10 kw. demanded.

DUNDEE: *Coal Supplies.*—The Special Committee of the Council which was appointed to inquire into the system of coal supply to the electricity department, in consequence of a report on the matter by Mr. Richardson, the engineer, have now submitted a report in which the whole question is gone into very fully, and confirmed the statement that money could have been saved had the advice of the engineer been more closely followed.

EAST HAM: *Broken Trolley Wire.*—On Saturday one of the overhead wires on the tramway system in Station Road, Manor Park, snapped, but nobody was injured.

Tramways.—At a meeting of the Town Council on Tuesday, the Electric Lighting and Tramways Committee reported the acceptance by the North Metropolitan Tramway Co. of the Council's offer for acquisition of the section of track owned by them in Romford Road. The Borough Engineer and the Engineer and Manager were directed to prepare plans and estimates for the construction of the track and overhead equipment along this section of road. A report is also to be presented on the question of inter-running with West Ham along the Romford Road.

ELLAND: *Projected Tramways.*—It is reported that a company is being promoted to construct tramways connecting Elland, Rastrick, and Huddersfield. The carrying out of the scheme will mean the construction of lines from West Vale, the extreme point of the Halifax service, to Fartown, the nearest point of the Huddersfield service. The gauges of the two services are different, but this difficulty is to be met by the laying down of a third rail. Parliamentary sanction to the scheme has already been obtained.

ERDINGTON: *Tramways.*—The report on the working of the tramways from the date of their inauguration on April 22nd, 1907, to January 31st, 1908, shows total receipts £9,970, or an average of 10·67d. per car mile. The expenditure has been £8,562, leaving a balance of £1,408, out of which provision for a reserve would have to be made.

FOLKESTONE: *Electricity Works Rifle Club.*—At the annual general meeting of the Rifle Club formed of the employees of the Folkestone Electricity Supply Company, last week, Mr. T. Hesketh, Chief Engineer of the company, was re-elected captain as well as hon. secretary and treasurer.

GUILDFORD: *Electrical Exhibition.*—The Guildford Electricity Supply Co. have been awarded a gold medal for their

Digitized by Google

exhibit of applications of electricity at the Trades Exhibition at the Guildford Drill Hall, last December.

LEEDS: *Electric Power Charges.*—A deputation of electric power users in Leeds waited upon the Council last week to ask for a reduction in the charges for energy for lighting, where this was used to a large extent on the premises of consumers taking considerable quantities for power purposes. It was suggested that a reasonable proportion should be given at power rates for lighting purposes, and, as instances, were mentioned Bradford, where 5 per cent. of the energy for power purposes could be used for lighting, and West Ham, where 10 per cent. could be so used. It was further pointed out that the tariff for power at Huddersfield was 1d. with discounts, which reduced this to ¾d. per unit in the case of large consumers, whilst in Bradford the minimum rate was ¾d. with discount, which reduced it to ½d. per unit.

Price of Electrical Energy.—A deputation representing some of the leading local manufacturing firms waited last week upon the City Council in order to urge that the price charged for electrical power should be lowered to a scale more nearly corresponding with that charged to large consumers in neighbouring towns, such as Bradford, where the minimum rate was stated to be ¾d. per unit, with discount, which brought it practically down to ½d.

LONDON: *London County Council: Hammersmith-Harlesden Tramways.*—The Board of Trade has consented to the use of the overhead trolley system for the portion of the tramways from Hammersmith Broadway to Uxbridge Road. Communications are taking place between the Board and the London County Council with regard to the similar consent concerning the Uxbridge Road to Harlesden Road tramway.

The Highways Committee recommend that arrangements should be made with Messrs. Reid Bros., who have the contract for laying the cable ducts along the road of the Hammersmith-Harlesden tramways, to undertake similar work simultaneously for the Postmaster-General, at an extra cost not exceeding £1,500, the Post Office paying a proportion of the cost.

Deptford: Opening of Roads.—The Works Committee of Deptford Borough Council call attention to the abnormal number of openings made by the L.C.C. in that portion of the roads which they are under obligation to repair as tramway authority. The L.C.C. is to be asked to minimise as much as possible the breaking up of streets consistent with the discharge of its statutory obligations.

Hammersmith: Franco-British Exhibition.—The Law and Parliamentary Committee report that the agreements with the Franco-British Exhibition Committee, and with the Kensington and Knightsbridge and the Notting Hill Electric Lighting Companies, regarding the supply of electrical energy to the Franco-British Exhibition, have been exchanged, and that the Exhibition Committee have paid the deposit of £1,000 as arranged. The Electricity and Lighting Committee, having had under consideration the question of improving the lighting of Wood Lane, has resolved upon the substitution of incandescent electric lights for the present gas lamps, of which there are at present 13, having a total candle-power of 295, the annual cost being £59 9s. 9d. The estimated cost of conversion (the present gas standards being used and fitted with the Osram metallic filament lamp) is £78 6s. 8d., the annual cost of lighting will be increased to £52, and the total candle-power increased to 1,144.

Hackney.—The London County Council have agreed to contribute one-third of the cost of street widenings in Mare Street and Lower Clapton Road for reconstruction of tramways, provided that the cost does not exceed £170,000. As, however, later estimates put the cost at £54,465, the Borough Council hope that the London County Council will agree to pay two-thirds of the cost.

Highgate Hill Tramways.—The Highways Committee of the London County Council report having had under consideration for some time past the question of the purchase of the undertaking of the Highgate Hill tramways. The tramways, which are worked by cable traction, consist of about ¾ route mile of partly double and partly single track, situated in London and Hornsey. The Council was in a position in 1903 to serve notice to acquire compulsorily, under section 43 of the Tramways Act, 1870, the portion of the undertaking situated in London, but the Council decided on October 20th, 1903, not to exercise its powers of purchase at that time. These powers of compulsory purchase will, in the ordinary course, recur in 1910. The company has introduced a Bill into Parliament in the present session (i) to authorise the company to reconstruct its tramways for electric traction on the standard gauge, (ii) to postpone the date of compulsory purchase of the lines by the local authorities, of which the Council is one, under the Tramways Act, and (iii) to confer on the company running powers over portions of the Council's tramways. The Council on January 28th, 1908, decided to petition against the Bill, and steps are being taken to oppose it accordingly. The company has, however, approached the Council with a view to the purchase by the Council at an early date of the whole of the company's undertaking by agreement under section 44 of the Tramways Act, 1870, in which event the company would not proceed further with its Bill. As the result of negotiation, the company has now expressed its willingness to sell its lines, &c., upon terms which the Committee feel justified in recommending the Council to accept. They accordingly suggest that a special meeting of the Council, of which one month's notice must be given, should be held under the provisions of the Tramways Act, 1870, to consider the matter as soon as practicable.

Islington: Electric Light Tariff.—The Lighting Committee have been empowered by the Council to modify, should they deem it desirable, the scale of charges to large consumers of electricity possessing high-load factors, provided always that such modification apply to all consumers taking current under the same conditions, and that every such modification be reported to the Finance Committee for their sanction.

London Electric Power Bills.—The Electric Lighting Committee reported at the last meeting that an informal conference of representatives of metropolitan borough councils owning electricity works, held at the Islington Town Hall on February 20th, the following resolutions were adopted:—(*a*) That those Metropolitan Borough Councils who are electric lighting undertakers be recommended to strenuously oppose the London Electric Supply and the London and District Electricity Supply Bills now before Parliament. (*b*) That in the opinion of this conference the development of the electricity supply of London can best be carried out by a combination of the existing undertakers. (*c*) That all the Metropolitan Borough Councils be recommended to authorise their electrical or consulting engineers to confer with a view to the drafting of a scheme on the basis referred to in the preceding resolution, and to the submission of such scheme for consideration by the representatives of such Borough Councils at a meeting to be called for the purpose. (*d*) That the Islington Borough Council be requested to convene such further meetings as may be necessary. It was resolved that the resolutions be approved.

Lambeth.—An agreement has been sealed between the South London Electric Light Corporation and the Borough Council whereby the old-standing dispute with regard to the destructor is to be settled by the lighting of the Brixton Town Hall free of charge.

Marylebone.—The Borough Council Electric Supply Committee issued a report on Tuesday on the results of the last six months' working, which, though not covering a period equal as to revenue earning to half of a complete year, affords a fair guide as to the costs of working and probable gross revenue for the year. The average yield per unit sold to private consumers was 4·42d., compared with the average estimated last March of 4·65d. This diminution is brought about by the large proportion of new businesses at the cheaper rates of supply, and the fact that the more profitable among the old consumers have elected to be charged on the maximum demand rates, which give a low average price in proportion to the number of hours of burning in each individual case. During the year ended March, 1906, the average attained was 5·15d. per unit, and during the year following, 4·7d. During the current year it will probably be 4·42d. With regard to the working costs for the six months, the report states that they are at a higher rate than the Committee estimated, owing largely to the increased price of coal, and abnormal repairs both at the works and on the distributing system. There was a special charge of £1,734 in respect of the cost of rendering effective for its present work the accumulator charging set at a sub-station, purchased from the company, which was not included in the year's estimates. The management costs have been steadily reduced, and during the six months work out at 0·243d. against 0·270d. estimated for the year. The repairs charges have been considerably reduced during the current quarter, and this, together with further economies effected in the standing charges, should result in a more favourable return for the March quarter. For the reasons named, the Committee explain, the estimate of March last as to the year's working will not be realised, and the complete year's accounts may show a small deficit. The question of more economical costs of production is receiving the Committee's careful attention, and the Consulting Engineer is advising them on this as well as on the revision of the tariff of charges to consumers. The necessity for adopting active measures tending to a large increase in sales, in order to spread the very heavy standing charges for loan service, management, and distribution expenses over a large number of consumers, the Committee say they are fully alive to.

Poplar.—The second annual dinner and smoking concert of the electricity department was held at the Eastern Hotel, Limehouse, on Saturday, Mr. J. H. Bowden, Borough Electrical Engineer and Manager, presiding.

At the last meeting of the Borough Council, the report of the Electricity Committee, embracing the result of the inquiry of the Board of Trade Commissioner on the recent boiler explosion, was submitted. (The Commissioner's conclusions were given in Electrical Engineering, January 23rd, p. 115.) The committee, after full and careful consideration of the evidence at the inquiry, came to the conclusion that they were not satisfied with the organisation and qualifications of the present works staff, and said they had directed the engineer to report as to the qualifications of the staff, together with a scheme of re-organisation. The committee's action was approved.

Digitized by Google

A joint committee of the Works and Electricity Committees reported as to the installation of a new refuse destructor capable of supplying steam to the electricity undertaking. The committee agreed upon a scheme put forward by the Horsfall Destructor Company, of which the capital cost would be £17,700. The amount of loan on present destructor required to be paid off is £3,694. The annual cost was estimated at £5,345. Last year the disposal of refuse cost £5,293, but under the proposed scheme the receipts from by-products would be £3,608, reducing the net annual cost (on an average) of the last three years to £1,968. The joint committee propose that the Electrical Engineer should supervise and maintain the steam-raising plant, and that all repairs, cleaning, &c., should be carried out by his department. The committee's proposals were referred to the Finance Committee.

Stepney: Blyth's Wharf Scheme.—The Board of Trade has consented to the adoption of a 6,000 volt transmission system from the proposed generating station at Blyth's Wharf, subject to the usual conditions.

Woolwich: Hiring of Fittings.—The Borough Council has accepted the London County Council's terms and conditions both with regard to the proposed loan of £3,000 for the supply, on the hire rental system, of arc lamps, motors, radiators, and wiring, and to the appropriation of an existing loan of £3,000 for hire-purchase purposes, and a mortgage has been sealed to secure the former, repayable in ten years.

MIDDLESBROUGH: *Electricity Supply.*—At a recent meeting of the Electric Lighting Committee, Mr. H. Taylor, the Electrical Engineer, reported a reduction of the units sold to 123,000, as against 150,000 for the previous year, and a corresponding reduction in income from £1,688 to £1,646. This was accounted for partly by the rise in the price of coal and partly by the shipyard strike.

NEWCASTLE-UNDER-LYME: *Tramways.*—The Council has decided to rescind its resolution refusing consent to the doubling of the existing tramway track by the Potteries Electric Traction Co., for which the company now has a Provisional Order before the Board of Trade.

NEWPORT: *Sunday Trams.*—The employees of the Corporation tramway system are protesting against the proposal to run trams on Sundays, which is now under consideration by the Corporation.

OLDBURY: *Transfer of Provisional Order.*—The Council has sealed an agreement with the Birmingham & Midland Tramways, Ltd., for the transfer of their electric lighting Order. An agreement has also been entered into with the company with regard to the working of tramways in the district. The agreements are to be submitted to the Local Government Board for approval.

SWINDON: *Telegraph Breakdown.*—Owing to the breakage of an iron telegraph pole on Tuesday night of last week, after a heavy fall of snow, the town was without telegraphic communication for two days, and the local papers appeared without any telegraphic news. The pole which carried the trunk lines fell across a house and dragged down several other poles.

YORK: *Tramways.*—The application for the construction of electric tramways by the Corporation, which was opposed by the North-Eastern Railway Co., has been granted by the Light Railway Commissioners on condition that special arrangements were made for the protection of and access to the station. The whole scheme involves a cost of about £128,000. The route proposed is about six miles in length, partly single and partly double track. The cost of the electrical equipment, on the surface contact system, is estimated by Mr. J. W. Hame, City Electrical Engineer, at £24,294. The route along Micklegate is to be abandoned in order not to interfere with Micklegate Bar.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ASTON MANOR.—The Corporation invite tenders for one 300-kw. and two 400-kw. turbo-alternators with the necessary starting and field controlling gear. Full particulars from Mr. R. Foster, Borough Electrical Engineer (fee £1 1s., returnable), and tenders to the Chairman of the Electricity Committee, Council House, Aston Manor, by March 14th.

The Corporation invite tenders for the extension of the power station at Chester Street. Particulars from the Borough Surveyor, fee £1 1s. (returnable), and tenders to the Chairman of the Electricity Committee by March 16th.

BELFAST.—The Tramways and Electricity Committee invite tenders for twelve months' supply of stores, including electrical accessories. Particulars from the rolling stock superintendent, Tramway Offices, Napier Street, and tenders to the Town Clerk by March 16th.

BOLTON.—The Tramways Committee invite tenders for stores during the year ending March 31st, 1909, including overhead materials, lighting materials, trolley pole, sundries, gear and pinion wheels, and brakeblocks. Full particulars from Mr. A. A. Day, Chief Engineer and Manager, and tenders to the Chairman of the Tramways Committee, Town Hall, by March 16th.

The Electricity Committee invite tenders for stores, including lubricating oils, joint-boxes, service fuse-boxes, &c., meters, mains sundries, motors and transformers, and motor-starting switches. Particulars as above, and tenders to the Chairman of the Electricity Committee by March 26th.

BURNLEY.—The Guardians for the Burnley Union invite tenders for electrical supplies for the ensuing year. Tenders close on March 16th.

BURY.—The Corporation invite tenders for the supply, delivery, and erection of two 2,000-kw. turbo-alternators with exciters and condensers. Specifications and general conditions may be obtained from Mr. S. J. Watson, Electricity Works, Bury (fee £2 2s., returnable), and tenders to the Town Clerk by March 16th.

DEWSBURY.—The Electricity Committee invite tenders for surface condenser and cooling tower. Full particulars from the electricity works (fee £1 1s., returnable), and tenders to the Chairman of the Electricity Committee by March 30th.

ERITH.—Tenders are invited for stores for the year ending March 31st, 1909, including carbons, meters, lamps, cables, joint boxes, bitumen, insulating tapes, and compound and cut-outs. Specification and forms of tender from the Chief Electrical Engineer (fee £1 1s., returnable), and tenders by March 18th.

FARNWORTH.—The Council have decided to spend £7,000 on transforming plant, extensions, and other purposes connected with their electricity undertaking. The Engineer has been instructed to prepare plans.

FELIXSTOWE.—A storage battery and booster are required. Tenders by March 25th. (See advertisement this week.)

GILLINGHAM.—The Council invite tenders for the supply of electricity meters and lubricating oils during the ensuing twelve months. Particulars from the Borough Electrical Engineer, and tenders to the Town Clerk by March 23rd.

GLASGOW.—Tenders are invited for:—(1) Large water-tube boilers; (2) 1,000 kw. motor generator and rotary converter; (3) extra high-tension and direct-current sub-station switchgear. Tenders to the Town Clerk by March 24th. (See advertisement this week.)

HALIFAX.—The tramways manager has reported that considerable renewals to the track and electrical equipment are required. The total estimated cost of the renewals and new loop lines recommended amounts to £10,870.

HEYWOOD.—The Electricity Department invite tenders for the supply, delivery and erection of the following:—(1) A Lancashire boiler, feed pump, steam, feed, and blow-off piping, water filter, and economiser; (2) steam engine and dynamo, condensers, air and circulating pumps, water-cooling tower, exhaust and circulating piping, return water and oil separator pumps; (3) lighting switchboard, alterations to traction generator, panels, combined booster and balancer set, and cable connections between machines and boards. Full particulars from the Consulting Engineer, Mr. J. R. Salter, Atherton, Lancashire, fee £3 3s. (returnable), and tenders to the Chairman of the Electricity Committee, Town Hall, Heywood, by March 16th.

ITALY.—The *Gazzetta Ufficiale* of February 26th contains a copy of a decree authorising the Tramvia Automotofunicolare di Catanzaro to construct and work an electric tramway for the transport of passengers and goods between the railway station of Catanzaro Sala and the piazza Independenza in the town of Catanzaro. The *Gazzettas*, containing further information, may be seen at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

LANCASHIRE COUNTY ASYLUM.—Tenders are requested for the supply of electrical goods and supplies to the Lancashire County Asylum, Preston, for the year ending April 5th, 1909. March 13th and March 19th are the respective dates for tendering.

LANCASTER.—The electrical engineer has reported that a new cable and alterations to the switchboard at the Town Hall are necessary, at an estimated cost of £275.

LEEDS.—The Electric Lighting Department invite tenders for the supply of steam coal and various supplies, including rubber-covered cables, main boxes, jointing and insulating material, electric lamp fittings, and sundries. Particulars from the Manager, and tenders to the Town Clerk by March 31st.

LONDON: *London County Council.*—The L.C.C. on Tuesday sanctioned the borrowing by Islington Borough Council of £6,935, for extension of mains and house services in connection with the electricity undertaking.

Tenders are invited for (*a*) about 32 miles of high-tension three-core lead-covered electric cables, &c., and (*b*) about 50 miles of low-tension lead-covered electric cables, &c., and about 30 miles of telephone cables for the Council's tramways. Tenders by March 21st. (See an advertisement.)

Fulham.—The Electricity and Lighting Committee has acquiesced in the proposed erection by the Electrical Engineer of a suitable pavement transformer chamber, at an estimated cost of £356. The committee has also adopted the recommendation of the Electrical Engineer to expend £159 10s. for the adequate equipment of the workshop at the electricity works, in order that the department may undertake its own repair work, &c. The tools proposed to be obtained are a planer (4 ft. by 2 ft. by 2 ft.), a radial drill (3 ft. 6 in. radius of arm, with tool-table beneath), a small 3½ in. mechanics' lathe, and a small bench emery grinder.

Poplar.—The engineer reported, with regard to provision to be made to meet next winter's maximum load, that the present plant has been loaded up to danger zone during this winter, and that it would be necessary to provide for an increase of not less than 400 kilowatts. The Electricity Committee have negotiated with several supply companies for a bulk supply, but, on the most favourable terms offered, the cost would be far in excess of that at which the current could be obtained by an extension of the Council's own generating plant, space for which is available in the existing buildings. The provision and maintenance of an additional generating station at Millwall would be exceedingly costly by reason of want of diversity of supply, costly coaling and condensing arrangements, duplication of standby plant, duplication of generating staff, and cost of land in excess of that necessary for a sub-station. The engineer states that he does not consider batteries effective plant; there is grave risk in relying upon them for anything but occasional peak loads, while the absence of standby and the heavy cost of upkeep are against present reconstruction or extension of the batteries to temporarily meet the increased demand. The engineer's proposal is to replace an existing 200 kw. generating set with a 1,000 kw. turbo-generator capable of developing a 20 per cent. overload, and the provision of an additional boiler. This would complete the equipment of the present station, and any further extensions required would necessitate an extension of the existing buildings. The installation now proposed, with the steam afforded by the new dust destructor, is expected to render further extensions of the generating plant unnecessary for at least three years.

Capital expenditure must also be incurred for distributing plant, including new feeders, additional sub-station and sub-station plant. In regard to this the engineer reports that during the winter portions of the distributing system have been strained in an equal proportion to the generating system, most of the feeder cables have been overloaded, thereby wasting a considerable amount of energy, and causing not only loss in revenue, but necessitating generating power which would otherwise have been avoided. To comply with statutory requirements as to voltage of supply and to keep the efficiency of the distribution system within economical limits, certain alterations and additions were necessary. In the north district the existing sub-station has not yet been brought into use. This is now absolutely necessary, as several complaints of low voltage have been received. Opening this sub-station would bring into operation one feeder which has hitherto lain dormant, and it will also be necessary to lay a new feeder and connect the Old Ford feeder with the sub-station. In order to start up, the engineer proposes to re-transfer a 250 kw. set from Glengall Road station to the northern sub-station, and instal a new duplicate set of 250 kilowatts in reserve. In the central district the feeder to Coborn Road must be extended, and a new feeder must be laid from the generating station to High Street, Poplar, in order to relieve the load on adjacent feeders, and to supply large new demands. The demand for current in the southern district has been much more rapid than was anticipated. It has been difficult to cope with the winter's load on account of the variable lengths of feeders out of the Glengall Road station and the overload upon them. At times it has been necessary to raise the bus-bar voltage, which would normally be at 480/490 to 522. This represents a demand upon the generating station of 1,370 kw., but if it had been possible to maintain the supply at 480 bus-bar voltage, the demand upon the station would have been only 1,260 kw. As the demand increases, the bus-bar voltage will rise still further, and the voltage of supply will become more variable and unsatisfactory. In these circumstances a second sub-station in the extreme south of the area is absolutely necessary. The engineer estimates the cost of the generating and distributing extensions now proposed will be about £27,200. The Council provisionally approved the extensions indicated, and authorised the committee to obtain tenders from selected firms for the types of plant required.

St. Pancras.—Tenders are invited for the supply of arc lamp carbons for twelve months. Full particulars from the Electricity Offices, 57 Pratt Street, Camden Town (fee, £2, returnable), and tenders to the Town Clerk by March 23rd.

MANCHESTER.—The Electricity Committee invite tenders for the supply, delivery, and erection at the Stuart Street Generating Station of a 6,000-kw. turbo-alternator with exciter and condenser plant complete. Particulars, &c., from Mr. F. E. Hughes, Secretary to the Electricity Department, Town Hall, Manchester (fee £2 2s., returnable), and tenders to the Town Clerk by March 25th. Further particulars and information can be obtained from Mr. S. L. Pearce, Chief Electrical Engineer, Dickinson Street, Manchester.

OLDHAM.—Sanction has been received from the Local Government Board to borrow £1,500 for meters.

RAWTENSTALL.—Tenders are invited for the supply, delivery, and laying of steel rails, points, crossings, and accessories for the tramway permanent way. Full particulars from Messrs. Lacey, Sillar & Leigh, 2 Queen Anne's Gate, Westminster, London, and 78 King Street, Manchester (fee £5 5s., returnable), and tenders to the Town Clerk by March 27th.

Tenders are also invited for the supply, delivery, and erection of a 192-tube economiser, also direct and alternating current meters. Particulars as above, and tenders to the Town Clerk by March 23rd.

SOUTHEND.—A Local Government Board inquiry was held last week into the application of the Town Council for sanction to borrow £26,690 for extensions to the electricity undertaking. During the course of the proceedings it was stated that it is proposed to spend £10,134 upon the provision of a condenser which, it is anticipated, will effect a saving of £466 per annum. The estimates for the ensuing year show a profit on the undertaking of £2,000.

SPAIN.—The *Gaceta de Madrid* of February 19th contains a copy of a decree authorising the Spanish Government to call for fresh tenders for the telephone construction. This contract comprises (*a*) the construction and working of the inter-urban service of the north-west; (*b*) the construction and working of the inter-urban service of the south-east; (*c*) the construction and working of the inter-urban service of the south; (*d*) the extension of the inter-urban service of the north-east, the addition of 19 new stations, and the working of the system. Tenders for each or all of the sections will be received up to noon on April 2nd, 1908, and deposits of (*a*) 182,000 pesetas (about £6,216); (*b*) 145,000 pesetas (about £5,000); (*c*) 150,000 pesetas (about £5,172); and (*d*) 167,500 pesetas (about £5,776), will be required to qualify tenders, these deposits being calculated as 5 per cent. of the value of the work.

The *Gaceta* of February 21st contains a notice to the effect that the municipality of Valencia are prepared to receive offers for the contract of electric lighting in the city during a period of 30 years from January 1st, 1910.

The *Gaceta* of February 22nd contains a notice to the effect that the Dirección-General de Obras Publicas of Madrid are prepared to receive offers, which must be presented within one month, for a concession for an electric tramway between Sevilla and Camas, on terms more favourable to the Government than those of the offer already presented by the Sevilla Tramways Co., Ltd.

Under similar circumstances the Dirección are prepared to receive offers for a concession for an electric tramway from the calle de Valencia, Barcelona, to the calle Alta de San Pedro, for which an application has been made by the Cia. de Ferrocarril de Sarria at Barcelona.

The Cia. del Tranvia Urbano de Bilbao have also applied to the Dirección for a concession for an electric tramway from calle de Fernandez del Campo to the goods station of the Santander-Bilbao railway at Bilbao, and competing offers may be presented under the conditions named above.

STOKE-UPON-TRENT.—Tenders are invited for a 300-kw. steam generator (single acting engine and direct-current dynamo), together with a water-tube boiler and surface condensing plant. Full particulars from Mr. P. J. S. Tiddemann, Electrical Engineer, and tenders to the Chairman of the Electricity Committee by March 14th.

SUNDERLAND.—The Sunderland District Electric Tramways Co. invite tenders for the three additional turnouts on their line between Philadelphia and Silksworth. Tenders to the Manager by March 27th.

SWEDEN.—H.M. Consul at Gothenburg has forwarded a copy of the conditions and drawing relating to a call for tenders for the supply of two large traverse-cranes, required for the large water power station of the Kungl. Trollhätte Kanal och Vattenverk (The Royal Trollhättan Canal and Water Works) at Trollhättan, whence copies of the specification and conditions of tender may be obtained. Further information will be given by the Superintending Engineer of the Water Works. Tenders must be received not later than midday on March 21st. The conditions and drawing may be inspected by British makers on application at the Commercial Intelligence Branch of the Board of Trade, 73 Basinghall Street, London, E.C.

SYDNEY.—Manufacturers and dealers in electric lighting supplies and plant, especially metallic filament lamps and flame arc lamps, are invited to send catalogues and other literature to Mr. H. R. Forbes, electrical engineer to the Municipal Council of Sydney, addressed, Town Hall, Sydney, New South Wales.

WARRENPOINT.—It has been decided to invite Mr. Pegg, of Messrs. Wilson, Miller & Pegg, to attend the next meeting of the Urban District Council in connection with the proposed electric lighting scheme for the town.

WEST HAM.—The Finance Committee have recommended that application be made to the Local Government Board for a loan of £51,600 for the electric light department.

WIGAN.—Tenders are required by March 25th for alternatively an electric light installation and a gas installation for the new workhouse infirmary at Billinge. Particulars from Messrs. Heaton, Ralph & Hendon, architects, Wigan.

Digitized by Google

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA: *Queensland.*—The tender of Mr. R. B. Hungerford, of Sydney, has been accepted by the Postmaster-General's Department for the supply and delivery of a common battery switchboard at Brisbane, together with 650 subscribers' telephones; the tender also includes increasing the capacity of the main frame, intermediate frame, and multiple jacks of both junction and subscribers' sections of the switchboard, for a total sum of £7,016 15s.; also for the supply and delivery of additional apparatus required on the present magneto board at £195.

BAILDON.—A scheme submitted by the Bradford Electrical Engineering Co. for the electric lighting of the district is under consideration by the Council.

BELFAST.—The tender of Messrs. Callender's Cable & Construction Co., for the supply of cables to the Electricity Department has been accepted.

BIRMINGHAM.—The tender of Messrs. Johnson & Phillips for the equipment of a 6,000-volt transmission line for the Birmingham, Tame, and Rea Drainage Board has been accepted.

BLACKBURN.—An order has been placed with the British Thomson-Houston Co., Ltd., for the supply of new tramcars.

BRISTOL.—The Electricity Committee have accepted the following tenders in connection with the Avonmouth scheme:—Messrs. Bruce Peebles & Co., three 3-phase to direct current converters, £3,647; Messrs. Clapham Bros., hot well and cooling tanks, £386 10s.

CLEVELAND.—Messrs. Bolckow, Vaughan & Co. have ordered two surface-condensing plants from the Mirlees Watson Co. for the Cleveland Ironworks, South Bank.

DUNDEE.—Further contracts have been placed in connection with the new electricity works, amounting in the aggregate to about £21,000. The tenders in question are for the switchgear and transforming plant for the power-house and sub-stations, which have been divided between the British Thomson-Houston Co. and the British Westinghouse Co. The contracts for carbons have been given to Messrs. Crompton & Co. for 12,000 pairs, the Union Electric Co. for 1,000 pairs, and the Oliver Arc Lamp Co., 12,000 pairs. The contract for oil has been granted to Messrs. Alexander Pringle & Co., Dundee.

GRANGE-OVER-SANDS.—The tender of W. Till has been accepted for the buildings of the electric power station at the Westmorland Consumption Sanatorium.

HULL.—A report has been submitted by the Electrical Engineer (Mr. Bell) upon the six tenders, mentioned in our last issue, which have been received for new generating plant. The acceptance of the tender of the Lahmeyer Co. (£4,591) was recommended, and a long explanation was given of the reasons which led him to favour the acceptance of this tender rather than either of those of British manufacturers at lower figures. After some discussion the recommendation was adopted.

LEEDS.—The electric lighting department have accepted the tender of the Mirlees Watson Co. for a surface-condensing plant.

LONDON: *London County Council.*—The Highways Committee have considered the 19 tenders, which were received for the rebuilding of the two bridges carrying Caledonian Road over the Great Northern Railway and the Regent's Canal, in connection with the electrification of the tramways in that thoroughfare, viz., Dick, Kerr & Co., Ltd., London, £6,895 11s. 2d.; W. Muirhead & Co., Ltd., London, £7,030 10s. 5d.; Joseph Westwood & Co., Ltd., Millwall, £7,152 14s. 3d.; Rowlingsons & Co., London, £7,355 8s. 3d.; Rawkins & Jackson, London, £7,497; P. Wilson & Co., London, £7,497 5s. 5d.; Orr, Watt & Co., Ltd., Motherwell, N.B., £7,584 14s.; W. Manders, Leyton, £7,615 7s. 1d.; D. R. Paterson, Ltd., Camden Town, N.W., £7,679 7s. 6d.; Greig & Matthews, London, £7,868 17s. 4d.; D. G. Somerville & Co., London, £8,114 6s. 9d.; W. Pattinson & Sons, Ltd., Westminster, S.W., £8,231 10s. 1d.; A. Jackaman & Son, Slough, £8,349; Heenan & Froude, Ltd., Manchester, £8,896 12s. 7d.; Anthony Fasey & Son, Leytonstone, £8,902 10s. 10d.; Alfred Thorne & Sons, Westminster, S.W., £9,562 7s. 6d.; The Motherwell Bridge Company, Ltd., Motherwell, N.B., £10,035 7s.; Pedrette & Co., Finsbury Park, N., £10,348 1s. 8d.; Thos. W. Pedrette, Bush Hill Park, N., £10,601 3s. 6d. The chief engineer's estimate comparable with the above tenders is £7,842. The Committee recommend that the lowest, namely, that of Messrs. Dick, Kerr & Co., Ltd. (£6,895 11s. 2d.), be accepted. The firm proposes to sublet the supply of the steelwork, and no objection is taken to this course.

The following tenders have been received for wiring and fitting the new Holloway fire station:—W. J. Fryer & Co. (accepted), £185; Nursey & Marr, £200; W. G. Cannon & Sons, Ltd., £248 13s.; John Bryden & Sons, £256; Duncan, Watson & Co., £275; J. O. Grant & Taylor, £320.

The following tenders have been received for the supply and delivery of about 525 tons of track rails and fastenings required for the reconstruction of the tramways from Brixton Road to near Camberwell Green. The amounts of the tenders are as follows:—Walter Scott, Ltd., Leeds, £3,978 2s. 6d.; Bolckow, Vaughan & Co., Ltd., London, £4,053 11s. 5d.; Barrow Hæmatite Steel Company Ltd., London, £5,062 1s. 3d. The chief engineer's estimate, comparable with the above tenders, is £5,816 2s. 6d. The Committee recommend that the lowest should be accepted.

Battersea.—The Lighting Committee of the Borough Council has accepted, subject to usual approval, the following tenders for annual supplies for the electricity department:—Price's Patent Candle Co., Ltd., oils; W. H. Wilcox & Co., engine-room stores (with the exception of packings); K. Beldam and Co., asbestos, &c., packings; Foster & Co., coal (1bstock peas and Mardy small nuts); Hudson & Co., coal ("Broomhill" bituminous); Sloan Electrical Co., Ltd., carbons for arc lamps, &c.; Ferranti, Ltd., ampere-hour meters; British Thomson-Houston Co., Ltd., watt-hour meters; Electrical Co., Ltd., Nernst lamps and fittings; Edison & Swan United Electric Light Co., Ltd., and General Electric Co., Ltd., incandescent electric lamps; Pryke & Palmer, ironmongery, tools, &c.; Callender's Cable & Construction Co., Ltd., bitumen, compound, and cable jointing. No tender has been accepted for service boxes, &c., but these goods are to be obtained from Callender's Cable & Construction Co., Ltd., and the British Insulated & Helsby Cables Co., Ltd., as required.

Hammersmith.—The Electricity Committee recommend (subject to the usual sanction) that the tender of Messrs. Babcock & Wilcox (£1,285) be accepted for a water tube boiler, and the tender of the Stirling Boiler Co. for a similar boiler at £1,671.

Poplar.—The Electricity Committee, in view of the present low price of copper and the probability of an early advance, authorised the Engineer to enter into an arrangement with the Western Electric Co., who submitted the lowest quotation in competition with other companies, for the purchase by the company of 30 tons of copper to be made up into cable as required by the Council in the next two years, at a fixed schedule of prices. The Council approved this course.

Stepney.—The Borough Council has received the following tenders for annual supplies in connection with the electricity undertaking:—Arc lamp globes, City Glass Co. (accepted), (*a*) total, assuming quantities are ordered, £64 7s. 6d., (*b*) remarks, first delivery end of eight weeks, instead of four weeks as required by the specification; Carl Quitman (*a*) £51 0s. 10d., (*b*) the Borough Electrical Engineer and Manager informed the Council that this amount by an accompanying letter is increased to £68 18s. 1½d. Rubber cable: Baxter & Caunter (accepted), £122 12s. 6d.; W. T. Henley's Telegraph Works Co., Ltd., £149 14s.; T. A. Glover & Co., Ltd., £149 14s. 2d.; India Rubber, Gutta Percha, and Telegraph Works Co., Ltd., £153 10s. 9d.

Westminster.—At the meeting of the City Council on March 5th, the recommendation of the Works Committee, that the tender of the Westminster Electric Supply Corporation be accepted for the lighting required in connection with the Marble Arch Improvement scheme, was adopted.

Woolwich.—The Borough Council has accepted the following tenders:—Maintenance of electric light and power installations, bells and telephones, at Plumstead and Woolwich Baths, for a period of five years, E. P. Allam & Co., £110 per annum (E. J. Wilkin and Son tendered at £160); two spare armatures and two field coils for the public wash-house, and one spare armature and one field coil for the establishment ironing-room at the Plumstead Baths, Siemens Bros.'s Dynamo Works, Ltd., £59 15s. (less 2½ per cent. if paid within a month of presentation of invoice).

NORWICH.—The Corporation has accepted the tender of Messrs. Laurence Scott & Co. for an electric motor at £450.

RAWTENSTALL.—The District Council has placed a contract for the supply and erection of a traction storage battery and booster with the D.P. Battery Co.

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the meeting on Thursday:—*Associate Members:* H. E. I. Bax, C. Bollam, H. M. Cuff, F. J. Gerard, W. J. Gray, T. Hall, T. H. Hurst, H. Lees, A. N. Rye, D. Sinclair, Lieut. E. J. Stevens, R.A., H. E. Turner, C. Wade, J. M. Walshe, A. E. Wilkins, J. W. F. Wyatt. *Students:* W. H. Apthorpe, J. W. Arnott, R. H. Barbour, W. R. Brown, H. C. Chindian, N. J. Cook, H. C. Ellis, S. Fahmy, A. C. Fendick, J. Fleming, W. S. Gould, R. E. Grime, H. H. Hayhurst, G. S. Heime, J. A. Hogan, W. Holt, R. G. Isaacs, H. Jack, H. F. Jefferson, F. H. R. Lavender, S. W. Ledbrook, D. C. McPherson, H. J. Magrath, G. V. Massey, G. T. Medforth, W. A. Olds, C. Papageorge, W. H. Peberdy, W. Pitt, H. W. F. Pouter, J. L. Ridsdale, A. T. Robertson, C. I. Roddick, C. G. Saltren-Willett, A. G. Savill, J. F. Shipley, G. M. S. Sichel, P. Smith, S. Thompson, A. D. Villares, J. D. A. Vincent, A. Wadsworth.

COMPANIES' MEETINGS AND REPORTS

BRITISH ENGINE BOILER & ELECTRICAL INSURANCE.—At the annual meeting on Thursday, a dividend of 4s. 6d. per share, making 7s. 6d. for the year, and a bonus of 2s. per share was declared for 1907. The sum of £7,000 has been added to the reserve fund, bringing this up to £66,000 and £2,409 were carried forward.

BROMPTON & KENSINGTON ELECTRICITY SUPPLY.—At the ordinary general meeting on Tuesday, Mr. H. R. Beeton, chairman, presiding, the report and accounts given in our last issue were adopted. The chairman opened his speech with a reference to the death of Mr. William Page, who had been connected with the company for over seventeen years, and was on the Board at the time of his death. In moving the adoption of the report and accounts, he pointed out that the growth in capital expenditure during the year, chiefly in mains, had been rather less than usual owing to the generating plant not having been increased. Mainly owing to the increased cost of coal, the growth of the net revenue had been somewhat retarded, but due to savings in other directions, the total works costs per unit did not amount to the extra 10 per cent. in the cost of coal. The accounts showed only the small increase of £335, and the directors, in recommending the distribution of the same dividend as last year, and appropriating a similar amount to depreciation and reserve, carried forward a larger balance by nearly £1,000. In reply to a question, the chairman stated that the Board was inclined to agree to the suggestion of paying the dividends, less income tax, in future.

At a special meeting held subsequently, the promotion of the London Electricity Supply (Joint Committee) Bill was approved.

COUNTY OF DURHAM ELECTRICAL POWER DISTRIBUTION.—At the annual meeting at Newcastle on Tuesday, Dr. J. T. Merz presiding, the report and accounts given in our last issue were adopted.

HUELVA GAS & ELECTRICITY.—The report for 1907 shows a net profit of £3,222, to which has to be added £251 brought forward from last accounts. A dividend of 4 per cent. free of tax is recommended, and £1,000 carried to reserve. After writing off a number of small amounts, the sum of £743 is carried forward subject to directors' and auditors' fees.

MANSFIELD & DISTRICT TRAMWAYS.—The report shows a substantial increase in the receipts. After providing for debenture interest and the six per cent. dividend on the cumulative preference shares for 1907, there remains £888 to be carried forward. Depreciation will be dealt with in future accounts.

METROPOLITAN ELECTRIC SUPPLY.—Mr. W. Harrison Cripps presided at the ordinary general meeting on Tuesday. The report and accounts given in our last issue were adopted. He stated that the gross receipts had increased by £5,047 during 1907, but in view of the fact that during the previous year the company received about £5,000 in respect of the Marylebone portion of the undertaking, the actual increase was over £8,000. This, however, was somewhat less than the directors had anticipated, and they attributed the result mainly to the increased use of metallic filaments lamps, and partly to the fact that the last quarter was a poor one. At the same time, the directors did not believe that the increased use of metallic filament lamps would ultimately do the electric supply business any great harm. The figure for rent, rates, and taxes showed an increase of £200, and in this connection he had a complaint to make. One Borough Council had previously assessed the company at £9,000, but this has been increased to £21,000. Long and costly arbitration proceedings had to be taken, in consequence, with the result that £10,000 were struck off. Although the Borough Council had to pay the costs of the inquiry, the money came from the ratepayers, and the company, as one of the largest ratepayers, had to bear a share of this. With regard to the year 1908, the equivalent of 24,300 8-c.p. lamps had been added to their connections during the first nine weeks, compared with 14,000 in the first nine weeks of 1907. At a special meeting held subsequently, the London Electricity Supply (Joint Committee) Bill, of which the company is a promotor, was approved.

NEWCASTLE-ON-TYNE ELECTRIC SUPPLY.—The report states that the total connections to the company's system at the end of the year amounted to 92,764 h.p., showing an increase of 22,764 h.p. over last year's figures. The profit of the year, including balance of £2,145 brought forward from 1906, amounted to £87,597. Out of this there have been paid interest on debentures, loans, &c., £25,470, and interim dividends on the amount called up on the preference and ordinary shares, £20,457, leaving a balance of £41,469, which the directors recommend should be appropriated as follows:—In the payment of further dividends of 2½ per cent. on the amount called up on the preference shares, and 5½ per cent. on the amount called up on the ordinary shares, making the total dividends for the year 5 per cent., and 8 per cent. on the preference and ordinary shares respectively, £34,444; in transferring to depreciation, £5,000; and in carrying forward, £2,025. The revenue of the company has increased from £176,810 in 1906 to £240,469, a rise of 35 per cent. Under normal conditions this would have resulted in a corresponding increase in profit, but the cost of coal has been heavy, amounting to over £58,000 in excess of the previous year, which is much beyond the proportionate increase on the additional business done, the difference being due to the great rise in the price of coal. The expenditure on capital account during the year, for extensions to meet the demands of certain large consumers, and on the system generally, has been £218,934. A tunnel under the River Tyne is in course of construction between Carville and Hebburn. This direct connection between the power station at Carville and the main cable system of the County of Durham Electrical Power Distribution Company, Limited, at Hebburn, will increase the effective capacity of the existing main cable system north and south of the River Tyne. In December last the County of Durham Electrical Power Distribution Company, Limited, made an issue of £250,000 first mortgage debenture stock. In view of the fact that the existing profits of that company are considerably more than sufficient to meet this charge, and that this capital will be utilised for the development of the Distribution Company's system, which will result in a large demand for electricity from the Company under the existing agreement, the directors agreed that the company should guarantee the interest on this stock. This issue of stock was over-subscribed. The issue of capital foreshadowed in the last annual report was, for various reasons, postponed, and temporary loans have been obtained in the meantime to meet the ordinary extensions of the business. To discharge these obligations, and also to provide for the erection of a new power station at Dunston, in the county of Durham, further capital will be required. This new station is wanted to enable the company to cope with the steadily increasing demand for electric power on both sides of the river: over 27,000 h.p. of new business, in addition to that already connected, having already been contracted for. It is proposed, therefore, to make an issue of share capital in the near future, and with this object in view, an increase in the capital of the company of £500,000 is necessary.

At the annual meeting at Newcastle on Tuesday, Dr. J. T. Merz, who presided, stated that the company is spending £20,000 on a tunnel under the Tyne at Wallsend, in order to obviate the expense and inconvenience of carrying the cables up the Tyne, over the high level bridge at Newcastle, and back to Hebburn. It was estimated that this would save £12,000 in capital expenditure, in addition to £2,000 a year due to the electrical losses. The company also proposes putting down new works at Dunston-on-Tyne, where they had leased 30 acres of land, and intended installing at first 30,000 h.p. of plant. To meet the expenditure upon this station—namely, £250,000—and to pay off loans, it was proposed to issue £500,000 in £5 preference shares, and the same amount of ordinary shares. The report and accounts were adopted, and in answer to a question, the Chairman stated that the whole of the further capital has been purchased by Lloyd's Bank and others at a premium, and the preference shares would be sold to the public at par, and the ordinary shares at £1 premium.

O. C. HAWKES, LTD.—At the meeting held at Birmingham last week, the report abstracted in our last issue was adopted. The chairman said that the trading results were not as good as in 1906, but he saw indications of a return to their former prosperity. The electrical department, he said, was answering all their expectations.

STAR OMNIBUS.—At an extraordinary general meeting on Friday to consider the question of whether the company shall continue operations, or be voluntarily wound up, Mr. W. A. Perry, who presided, said that their present unsatisfactory position had been brought about by the fact that most profitable omnibus routes had been wiped out of existence by the London County Council tramways, which were being run at fares which could not possibly pay. Nearly every route in the suburbs of London had been covered by electric tramways, whilst when the omnibus companies sought relief in the centre of London they were met by the competition of tube railways.

W. T. HENLEY'S TELEGRAPH WORKS.—At the ordinary general meeting on Saturday, the report and accounts, given in our last issue, were adopted. During the course of his speech, Mr. S. Gedge, who presided, referred to the fact that 21 years ago the business of the company had been on sale provided their debts were paid, the company to sacrifice the remaining £70,000 of its share capital. They were all glad now that no sale was effected, as that £70,000 was worth at the present day £170,000. The profits for the past year admitted of the payment of a dividend of 18 per cent., and this would still have left a small margin for reserve. The directors had considered it wise, however, to divide only 75 per cent. of the profits, and to set the remainder aside.

PARLIAMENTARY INTELLIGENCE

LONDON ELECTRIC POWER BILLS.—In the House of Lords on Thursday, the Earl of Onslow moved that the London and District Electricity Supply Bill, the London Electric Supply Bill, and the London (Westminster and Kensington) Electric Supply Co. Bill, should be referred to a Joint Committee of both Houses of Parliament. In the course of a short speech his Lordship described briefly the objects of the three Bills in question, and stated that there were two opinions on the matter, viz., one, that the electrical supply business of the metropolis should be undertaken by a commercial company, and the other that it should be provided by municipal enterprise. He thought the time had arrived for carefully considering the whole position, and it was with the object of having the matter threshed out by the most competent tribunal that Parliament could appoint, that he asked that the Bills should be referred to a Joint Committee. The motion was agreed to, and has now to come before the House of Commons.

PROGRESS OF ELECTRICAL BILLS.—The London and Windsor Motor Roads, Tramroads, and Tramways Bill was read a first time in the House of Lords on Monday.

The Bristol Tramways Bill was read a second time in the House of Lords on Tuesday

ROCHDALE CORPORATION BILL.—This Bill was before the Unopposed Committee of the House of Commons on Monday, and was ordered to be reported for the third reading. Part IV. refers to some short lengths of new tramways, for which £2,500, repayable in 40 years, is to be borrowed. The period for construction is five years. Part VI. of the Bill authorises the supply of electricity in bulk outside the Corporation area, and also the use of the generating station for tramway purposes.

TELEGRAPH CONSTRUCTION BILL.—On the second reading of this Bill in the House of Commons, the text of which was given in our issue for February 20th, Mr. Harold Cox will move that it is undesirable to give larger powers to the Post Office until the House has been placed in possession of fuller information as to the financial results of the management of telegraphs and telephones by the Post Office. Motions have also been handed in by Mr. Courthope and Mr. G. Gibbs to the effect that the second reading should be postponed six months.

APPOINTMENTS AND PERSONAL NOTES

Messrs. Norman A. Thompson and J. G. Wilson, consulting engineers, of 22 North Bridge Street, Edinburgh, have dissolved partnership by mutual consent. Mr. Thompson will carry on the consulting practice.

The Woolwich Borough Council has appointed Mr. Ernest Wallace Martin, Woolwich, assistant distribution engineer, at a commencing salary of £90 per annum, rising by annual increments of £10 to £140 per annum. There were 43 candidates.

At the next meeting of the Islington Borough Council, recommendations by the Lighting Committee and the Law and Parliamentary Committee will be considered: that the following increases of salary be granted in the electricity department:—M. H. Adams, Constructional Engineer, £160 to £170; A. Jarratt, meter tester, £2 per week to £2 5s. per week.

The salary of Mr. W. J. Bache, City Electrical Engineer at Cheltenham, has been increased from £400 to £450 per annum from April 1st.

Mr. H. R. Forbes, formerly Resident Engineer for the London District to the Electrical Engineers' Department of the Great Western Railway, has been appointed Electrical Engineer to the Municipal Council at Sydney, New South Wales, and sails this month to take up his appointment.

Mr. W. H. Frazer having accepted the position of Chief Engineer to the Anglo-Portuguese Telephone Co., has resigned his position on the Engineer-in-Chief's staff of the National Telephone Co., and will be shortly leaving for Portugal.

Northampton Institute.—The sixth annual dinner of the day students of the Northampton Institute was held in the Queen's Salon, Holborn Restaurant, on Friday, February 28th. Mr. E. V. Pannel was in the chair, and among the guests were Dr. R. Mullineux Walmsley, Dr. C. V. Drysdale, Mr. H. M. Hobart, Mr. C. E. Larard, and others.

Electricity in Horticulture.—We understand that Mr. J. H. Priestley, Lecturer in Botany at the Merchant Venturers' Technical College, Bristol, has been carrying out experiments upon the effect of electricity on plants, chiefly from the point of view of the use of high-tension current. The Board of Agriculture has granted the sum of £50 to the College to enable experimental apparatus to be fixed in the College garden.

X-Ray Dermatitis.—At a meeting at Birmingham on Thursday to consider the question of providing assistance for Dr. Hall Edwards, who, as we stated in our issue for February 20th, has had one hand amputated through injuries caused in consequence of experiments with X-rays, it was decided to raise a fund which will be invested. £309 was subscribed in the room, and Sir Oliver Lodge, who presided, stated that the King was interested in the case, and a small Civil List pension might also be granted.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of 5 Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars net c.i.f., port of arrival, quoted on Tuesday night, was £59 to £59 10s. per ton (last week £58 15s. to £59 5s.).

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—Notice is given of an intended dividend in the bankruptcy of George Collier, trading as H. Collier & Co., gas and electrical engineer, 89 Long Acre, London. The last day for receiving proofs is March 18th. The trustee is Mr. E. L. Hough, Bankruptcy Buildings, Carey Street, London.

In the Chancery Division on Saturday, Mr. Justice Warrington was asked as a matter of urgency to appoint a receiver and manager of the "X" Accumulator Co., Ltd. Upon the company appearing and consenting, a receiver and manager was appointed.

The trustee in the bankruptcy of C. V. De Falke, electrical engineer, 17 Shaftesbury Avenue, London, has been released.

Telegraph Traffic.—The Governor of Jamaica in Privy Council approved under Section 2 of Law 7 of 1904, "The Telegraph Control Law," the following rules with respect to licenses under that law:—Every application for a licence must be signed and sealed and addressed to the Clerk in Privy Council, and delivered at Headquarter House, Kingston. Three copies of the licence; a description of the telegraphic apparatus, mechanism, or contrivance to be employed, plan on a scale not less than 1 in. to 100 ft., showing exact location of the proposed stations, detailed drawings of the apparatus must accompany the application. Certain rules are also laid down for advertising and notices, as well as penalties for infringement of the law. The state of telegraphic facilities in Central and South America does not appear to be at all satisfactory, as regulations imposing limitations on senders of telegrams have not been withdrawn, although in force for considerable periods; thus, private telegrams for Costa Rica, Nicaragua, and Honduras have been prohibited since 1903, excepting at sender's risk; telegrams for Cartagena, Barranquilla, and Santa Marta have been subject to delay since 1906; and restrictions are imposed in the Argentine. On the 6th instant the cable between Martinique and Guadeloupe became interrupted, cutting off this latter island by the French system, to whom the cable belongs. The point of connection between the West India & Panama Telegraph Co. and the French system being also at this island, these systems cannot exchange messages until the cable is restored. The cable between Chio and Tenedos of the Eastern Telegraph Co. was repaired on the 8th instant

Nuisance from Brighton Corporation Motor Generator Station.—In the Chancery Division on Saturday, Mr. Justice Joyce delivered a considered judgment in an action by the Rev. Edward Heath and others, incumbent and trustees of the Church of St. Mary and Mary Magdalen, Brighton, for an injunction to restrain the defendants from so using the machinery for the purpose of generating electricity as to cause a nuisance and annoyance to the worshippers. We have previously reported the case in our issues for January 23rd and 30th, and February 6th. Mr. Justice Joyce said the plaintiffs were not, because their premises were used as a place of worship, entitled to anything more than the ordinary amount of quiet they had in a town. They had no special right because of the purposes for which the church was used. As to what amount of noise, or annoyance from noise, would be sufficient to maintain an action there was no definite legal rule or measure. It was a question of fact in each case. In the present case, the locality was that of a large town, the neighbourhood being poor and certainly not within which could be described as a residential part of Brighton. A nuisance of the kind could not be excused merely on the ground that the works were in a suitable place, but in considering whether the comfort of the plaintiffs was materially interfered with, regard must be had to the character of the neighbourhood and surrounding circumstances. Upon the evidence, his Lordship thought the sound complained of could not be heard during any singing or playing of the organ, or when there was any other sound in the church. In certain parts of the church it could not be detected by listening, even when there was otherwise personal silence, and sometimes it could not be heard at all anywhere in the building. He thought the noise ought not to distract the attention of ordinary healthy persons. The law did not regard trifling inconveniences, and things of that sort must be looked at from a reasonable point of view. It was obvious that the granting of an injunction would be a serious matter in the case. He thought, on the whole, the plaintiffs had not established their right to relief. He was of opinion that the action failed, and must be dismissed. If the case went no further he suggested that the defendants might very well not insist upon costs. Mr. Astbury, K.C., on behalf of the Corporation, said his clients would consider what his Lordship had said with regard to costs. It may be pointed out that Mr. C. P. Sparks, Chief Engineer of the County of London Electric Supply Co., inspected the church and works, and reported to the court.

MISCELLANEOUS CITY NOTES

BRITISH INSULATED & HELSBY CABLES.—A dividend of 4 per cent., together with a bonus of 2 per cent., is recommended for the half-year to December 31st, making 10 per cent. for the year. The sum of £37,000 is transferred to reserve and depreciation, and £28,000 carried forward.

CANADIAN GENERAL ELECTRIC CO.—The Canadian Bank of Commerce, London, has received a telegram from Toronto stating that the directors of the Canadian General Electric Company, Ltd., in view of present industrial conditions in the United States and Canada, have considered it prudent in the meantime to reduce the dividend on the common stock to 7 per cent. per annum. They have accordingly declared a quarterly dividend of 1¾ per cent. for the three months ending March 31st, 1908, being at the rate of 7 per cent. per annum on the common stock.

DIRECT SPANISH TELEGRAPH CO.—The directors recommend a dividend of 4 per cent., free of Income Tax, on the ordinary shares for the half-year ended December 31st, 1907.

BRUCE PEEBLES & CO.—The petition against the appointment of Mr. A. W. Tait (London) and Mr. J. A. Robertson Durham (Edinburgh), joint liquidators in the voluntary winding up of Messrs. Bruce Peebles & Co., was heard at Edinburgh on Thursday. The petitioners represented creditors to the extent of £4,666. An objection was taken to the appointment of Mr. Tait, either alone or in conjunction with another, on the ground that he was a director of the company, and not subject to the jurisdiction of the Court. Messrs. A. A. Krauss & Sons, Bristol, suggested that the Court should appoint one official liquidator, or a joint liquidator with Mr. Robertson Durham, other than Mr. Tait. Having heard arguments, the Lord President, after pointing out that there was an overwhelming majority of shareholders in favour of the proposal to appoint the two gentlemen in question, stated that he saw no sufficient reason why the Court should disturb the liquidation that had been going on. He knew of no objection in law to appointing a liquidator because he was not subject to the jurisdiction of the Court, and whilst he admitted that the appointment of Mr. Tait as sole liquidator would have been objectionable, this objection was removed by the appointment of Mr. Robertson Durham as joint liquidator. Mr. Robertson Durham was well known in that Court, and it would be his clear duty to report to the Court when he thought the time had come, if it ever did come, that Mr. Tait should resign.

OFFICIAL ANNOUNCEMENTS AND SMALL ADVERTISEMENTS.

Official Advertisements are charged at the rate of **1/-** per line (column width).

Small Prepaid Advertisements of Situations Vacant and Wanted, Plant for Sale or Wanted, &c., are inserted at the rate of **1/-** for the first 12 words and 1d. per word afterwards. Three insertions for the price of two. Advertisements can be received up till Wednesday morning first post.

Letters should be addressed to THE KILOWATT PUBLISHING CO., LTD., 203–6, Temple Chambers, London, E.C.

TENDERS INVITED.

CORPORATION OF GLASGOW.

ELECTRICITY DEPARTMENT.

THE CORPORATION invite Tenders for the supply of the undernoted Plant from Firms who have experience in the manufacture of same, and can show similar plant in operation in this country:—(1) Large Water Tube Boilers; (2) 1,000 K.W. Motor Generators and Rotary Converters, and (3) Sub-Station Extra High Tension and Direct Current Switchgear. Copies of the Specifications and Forms of Tender may be obtained on application to Mr. W. W. Lackie, Engineer, 75, Waterloo Street, Glasgow, on making a Deposit of Two Guineas in respect of each Specification. The amount deposited will be returned on receipt of *bona fide* Tenders. Sealed Offers marked "Electricity Department, Tender for .....," must be lodged with the Subscriber not later than 10 a.m. on Tuesday, 24th March, 1908.

The Corporation do not bind themselves to accept the lowest or any offer.

A. W. MYLES,
Town Clerk.

City Chambers,
Glasgow.
10th March, 1908.

FELIXSTOWE URBAN DISTRICT COUNCIL.

THE URBAN DISTRICT COUNCIL of Felixstowe are prepared to receive tenders for the following.

STORAGE BATTERY AND BOOSTER.

Specifications, General Conditions, and forms of tender may be obtained on and after Saturday, March 14th, 1908, at the Offices of the Consulting Engineer, Mr. Reginald P. Wilson, 66 Victoria Street, Westminster, on payment of a sum of two guineas.

This sum is required as a deposit, and will, after the Council shall have entered into a contract upon the tenders received, but not before, be returned to the tenderer provided he shall have sent in a *bona fide* tender and shall not have withdrawn the same. In any other case the deposit will be forfeited.

The tenders must be sent in on the Official Form and all instructions contained therein must be complied with.

Tenders, endorsed "Storage Battery and Booster," must be addressed to the Clerk, Felixstowe Urban District Council, and must be delivered at the Town Hall, Felixstowe, not later than 12 noon on Wednesday, March 25th, 1908.

The Council do not bind themselves to accept the lowest or any tender.

F. B. JENNINGS,
Clerk to the Council.

Town Hall, Felixstowe.
March 7th, 1908.

TENDERS INVITED.

COUNTY OF LONDON.

THE LONDON COUNTY COUNCIL invites tenders for the manufacture, delivery, and laying of:—

(*a*) About 32 miles of high tension, 3 core lead-covered electric cables, &c., and

(*b*) About 50 miles of low tension lead-covered electric cables, &c., and about 30 miles of telephone cables for the Council's tramways.

Full particulars, and also information as to the conditions to be observed by tenderers, will be given in the *London County Council Gazette*, of 9th and 15th March, 1908. The Gazette, which is published weekly, contains particulars of all the tenders invited by the Council, and can be obtained from Messrs. P. S. King and Sons, 2 and 4, Great Smith Street, Westminster, S.W., price 1d., post free 1½d. an issue, or for the whole year a prepaid subscription of 6s. 6d. Tenders must be upon the official forms to be obtained from the Clerk of the Council at the County Hall, Spring Gardens, S.W., upon payment to the Cashier of the Council of the sum of £2 for each of the two specifications, &c. This fee will be returned only if a *bona fide* tender shall be submitted. No tender will be received after 11 a.m. on Saturday, 21st March, 1908. The Council does not bind itself to accept the lowest or any tender of any person or firm who shall on any previous occasion have withdrawn a tender after the same had been opened, unless the reasons for the withdrawal were satisfactory to the Council.

G. L. GOMME,
Clerk of the London County Council.

County Hall, Spring Gardens, S.W.,
4th March, 1908.

SUMMARY

The proposal in the House of Lords that the London Electric Power Bills should be referred to a Joint Committee of both Houses of Parliament was rejected in the House of Commons on Tuesday. (Page 424.)

Progress is being made with the preliminary arrangements for the Electrical Exhibition to be held in Manchester next October. The announcement made in our issue of March 5th, that the Exhibition will be held in Platt's Fields, is correct, and the rumour circulated by a contemporary that the Exhibition is to be postponed until next year is authoritatively contradicted. (Page 425.)

Prof. Schwartz and Mr. James write that their recent Paper dealt largely with enclosed fuses, "not because the Engineering Standards Committee were obsessed with the sinister intention of forcing rows of obese cartridge fuses into the distended jaws of consumers' distribution boards." Mr. S. G. C. Russell, Consulting Electrical Engineer to the Phœnix Fire Office, agrees with us that the standardisation of fuses is not necessary, but rather the standardisation of fuse-boards. Messrs. Eckstein, Heap & Co. announce that they make alternating-current motor-starting switches with no-voltage release. Mr. A. R. Bennett replies to Mr. H. L. Webb's letter in our last issue. (Page 425.)

The Paper read by Messrs. R. K. Morcom and D. K. Morris last week, before the Birmingham Local Section of the Institution of Electrical Engineers, considered the design of apparatus for artificially loading alternators for testing. The arrangement described consisted of a water resistance combined with specially designed choking coils for obtaining any desired power factor. In the discussion which followed several speakers gave their experiences with water resistances of other forms than described in the Paper, especially with circular iron tanks. The influence of the peculiar wave-form produced by the special design of choking coil described was also discussed. (Page 427.)

In last Friday evening's discourse at the Royal Institution, Mr. G. Marconi gave an account of the progress of Transatlantic wireless communication as carried out by his company, and outlined the developments which have taken place since the first signals received in 1901 to the improved methods with "semi-continuous" oscillations and aerials giving a certain amount of directive effect as used to-day. He complained of the attitude of some sections of the technical Press, which appeared to be attempting to protect the interests of the cable companies; and, although not giving any definite particulars of the amount of traffic which his stations could handle, he took up a most optimistic attitude as to the future. (Page 430.)

Digitized by Google

IN a Paper read before the Association of Engineers-in-Charge, Mr. H. D. WILKINSON outlined the main features of the control of electrically-operated lifts, and described in detail several particular safety devices. The question as to whether a worm gear was really self-sustaining or not was raised in the discussion, and the uselessness of the no-voltage release for lift work was referred to. (Page 431.)

IN a Paper read before the Manchester Association of Engineers last week, Mr. S. L. PEARCE dealt generally with the subject of steam turbine engineering. The leading types of turbine were described at some length and compared, and some of the principal advantages of the steam turbine over the reciprocating engine were pointed out. (Page 433.)

SOME advertising signs, in which special colour effects are obtained, have been put on the market. (Page 434.)

PROF. J. J. THOMSON has been nominated for the Presidency of the British Association at the Winnipeg meeting in 1909. (Page 434.)

SOME additional generating plant which has been necessitated at the Wolverhampton Electricity Works by the rapidly increasing power-load was inaugurated on Monday. Two new 1,000 kw. three-phase turbo-generator sets have been put down, the alternators of which are the first machines of this class made by the Electric Construction Co., and embody a number of interesting points of design, especially as regards the construction of the rotors. New boilers and a new switchboard have also been installed, as well as a 500 kw. motor-converter and a synchronous motor-generator of the same capacity, which serve as connecting links between the new three-phase sets and the older continuous-current plant in the station. (Page 435.)

AN automatic switch has been introduced for cutting small transformers for metallic filament lamps out of circuit when not in use, in order to avoid the all day open circuit losses. (Page 440.)

SIR WILLIAM H. PREECE, K.C.B., gave a lecture at the Institution of Electrical Engineers last Thursday, describing his impressions on revisiting America last year. He gave interesting figures with regard to the growth of telegraphy and telephony in the United States, and was enthusiastic over the Barclay type-printing telegraph machine, which has proved of great service in that country. In the course of his remarks with regard to the Electrical Testing Laboratory in New York, he mentioned that the Engineering Standards Committee (presumably the British one) is about to frame a specification for standards for metallic filament lamps. (Page 441.)

OWING to the recent drop in price of aluminium, and notwithstanding the present low price of copper, it is still claimed by the *Chemiker Zeitung* that aluminium is cheaper as a conductor than copper; and owing to the new process of welding it, which has recently been introduced by M. U. SCHOOP its use is likely to extend. Under "Electrochemistry and Electrometallurgy" short notes are also given on frothing in alkaline accumulators, forming of iron electrodes, and electrochemical industries in Norway. (Page 443.)

UNDER "Electrical Science," in the British and American Section, is given an account of Prof. J. J. THOMSON'S second lecture on electric discharges through gases, in which he continued to discuss the conductivity of gases at normal pressures. Some new and trustworthy formulæ for calculating the current and potential from a needle-point in air are also given. In the Papers abstracted in the Continental Section, GUILLET describes an electrical induction method of measuring very small lengths; REGENER counts the number of alpha-particles projected by polonium by means of the spinthariscope; and WIEN calculates the wave-length of Roentgen rays from Planck's law of radiation. (Page 444.)

IN place of the ordinary reading and discussion of a Paper, the meeting of the Manchester Local Section of the Institution of Electrical Engineers on Tuesday, March 10th, was devoted to a lecture by Mr. W. ROSENHAIN on the internal structure of metals, in which the bearing of the results obtained by the microscopic study of the crystalline structure of pure metals and alloys upon the explanation of some of their properties was discussed. (Page 445.)

AT a meeting of the Electrical Contractors' Association, Mr. L. GASTER read a Paper on metallic filament lamps, in which he described the leading types, and in particular the new Z lamp, which, it is claimed, will burn in any position, and is suitable for both alternating and direct current. (Page 445.)

A NEW form of universal photometer of American design is described. A modified Lummer-Brodhun arrangement of prism is used, and the comparison lamp is mounted on a sliding carriage. Measurement either of luminous intensity or illumination may be made. (Page 446.)

AMONG the patent specifications published last Thursday is one by V. A. FYNN, describing a method of obtaining the necessary phase displacement for starting single-phase motors of the split-phase type. A specification by the BRITISH THOMSON-HOUSTON Co. covers a method of prevention of electrolytic corrosion of buried pipes and cables by alternating currents, and consists in superimposing a uni-directional current on the alternating current. B. LAMME has patented a method of preventing single-phase series commutator motors from acting as direct-current generators. The patent for the well-known Reason double-cover two-pole fuse-box expires during the current week. (Page 447.)

CONSIDERABLE progress has been made with the inquiry at Caxton Hall, Westminster, into the proposed Home Office regulations since our last issue, mainly due to a very sensible suggestion that a private informal conference should be held between a Committee representing the objectors and the representatives of the Home Office. In this way, by adjourning at midday on Monday, an agreement had been come to by yesterday morning upon the details of the first 20 regulations (excepting Regulations 17 and 18, referring to switchboard galleries and passage-ways). Mr. A. P. TROTTER gave evidence on Monday in regard to overlapping between the existing Board of Trade regulations and the proposed rules of the Home Office. In order to avoid this, he proposed that an addition should be made to Board of Trade regulation A1, stipulating that it shall not apply to factories. Evidence was also given by Mr. E. GARSIDE, Managing Director of Engineering Instruments, Ltd., as to the manufacture of no-voltage releases for alternating-current motors. Both on Tuesday and Wednesday the sitting lasted only a few minutes. (Page 449.)

IT has been reported to the Bath Corporation that the term within which the electricity works were to be purchased by Mr. Schenk on behalf of the Somerset Electric Power Co., will expire on March 31st. A new proposition has been made, and is now under consideration, by which the deposit of £2,500 will be forfeited. The London County Council has made a proposition to the City of London Corporation for a conference with regard to tramways over Southwark Bridge. The owners of the patents of the Cope shallow conduit system of traction have offered to lay down a line between the cable tramway terminus at Murrayfield and the Edinburgh Exhibition free of cost, and to remove it, if necessary, at the close of the Exhibition. A letter has been received from the Board of Trade by the Hanwell Urban District Council regarding the condition of the tramway track in that district. The letter encloses a communication from the London United Tramways Co., which expresses the view that the complaints of the Council have grossly exaggerated the condition of

Digitized by Google

the track. It is proposed to form two companies, one for lighting and one for power, to take over the electricity undertaking of Johannesburg Corporation. The accounts of the Hackney Electricity Works show that for the fifth year in succession the generation and distribution costs are the lowest in the metropolitan area, namely 0·73d. per unit sold. An arrangement has been arrived at between the National Electrical Construction Co. and the Oxford Tramways Co., for the promotion of a new company to acquire the existing horse tramways and reconstruct them for electric traction on the surface contact system. The arrangement has to receive the sanction of the shareholders of the company and also of the Corporation. (Pages 451–453.)

The Ayr Corporation is to apply for sanction to borrow £30,000 to meet extensions of the electricity works during the next eight years. The Burslem Corporation has decided to apply for £12,000. A surface condenser and cooling tower is required at the Dewsbury Electricity Works; water-tube boilers, 1,000 kw. motor-generators, and extra high-tension switchgear at Glasgow; electrical stores at Edinburgh, Bolton, Bray, Belfast, Leeds, and Nottingham; double-deck tramcars at Wolverhampton; and battery and booster with switchboard at Whitehaven. (Pages 453 and 454.)

The report of the British Insulated & Helsby Cables, Ltd., shows a profit of £172,332, including £36,713 brought forward from last year. At the meeting of the Devonport & District Tramways Co., last week, Mr. W. G. Bond stated that failing a more satisfactory arrangement with the Devonport Corporation as to the terms of their lease, the Company was prepared to negotiate for the sale of the undertaking. The report of the City of London Electric Lighting Co. shows a balance available for distribution of £179,371, and a final dividend of 6 per cent. has been declared upon the ordinary shares. The sum of £20,474 is carried forward. The County of London Electric Supply Company's accounts show a net revenue of £109,089, and after deducting debenture interest and interim dividends, a further dividend of 6 per cent. per annum was declared upon the ordinary shares. At the meeting on Monday, Mr. J. B. Braithwaite, the chairman, stated that their connections in 30-watt lamps amounted to over one million lamps, which was a record for London. A profit of £23,120 is shown by the North Metropolitan Electric Power Supply Co. for the year 1907. After providing for debenture and loan interest, there is a balance of £12,672, and the directors recommend a dividend at the rate of 4 per cent. per annum, carrying forward £386. (Pages 456–458.)

We are happily able to give unreserved contradiction to a rumour circulated by a contemporary last week that the Electrical Exhibition to be held in Manchester in October would be postponed until next year. Far from this being the case, we announced a fortnight ago that the use of Platt's Fields, belonging to the Manchester Corporation, had been placed at the disposal of the Exhibition Committee, and, from the additional particulars, which we publish on another page, it will be seen that considerable progress has been made with the plans for the buildings, and that a draft prospectus and plans of floor space are being prepared for circulation to prospective exhibitors. There can be no doubt that the electrical industry will benefit considerably by this Exhibition, whether the existing depression is alleviated before October or not. Enormous strides have been made in economical electric lighting since the last general electrical exhibition in London, and it is meet that they should be effectively demonstrated to the general public. Of equal importance, moreover, is the fact that a special public is to be found in Manchester in the shape of large power-users, who should be made better acquainted with the great advances in electrical power applications during the past few years. This branch of the industry was rather neglected on the previous occasion, and the manufacturers of electrical plant should profit by the opportunity that will now be offered them to create new business relations in the Midlands and North of England, and to improve existing ones.

The subject treated by Mr. R. K. Morcom and Dr. D. K. Morris in their Paper read at Birmingham last week is one which most central engineers have had forced upon them, but has not often received such scientific treatment as it was given by these authors. The methods adopted for testing plant on site are usually crude in the extreme, and although many engineers will doubtless still be content to rig up wonderful arrangements of barrels and other material easily obtained locally—such as would cause the factory inspector of the future immediately to produce his book of regulations—Messrs. Morcom and Morris have suggested excellent means whereby a permanent artificial load with a wide range of usefulness may be constructed. The most valuable part of the Paper was the investigation into the design of special choking coils to be employed in conjunction with liquid resistances for obtaining heavy inductive loads with an accurately adjusted power-factor. The importance of such tests is often overlooked, and mainly on account of difficulties which are overcome by the apparatus described they are rarely carried out. Tests of this nature have not to be conducted with sufficient frequency in an average generating station to warrant the outlay on a special plant of the form suggested, but there is no doubt that some such arrangement for power-factor adjustment would be extremely useful in the test-room of a large manufacturing works.

By suggesting a series of conferences in Committee, the objectors to the Regulations drafted by the Home Office to govern the use of electricity in factories have considerably shortened the proceedings before the Commissioner appointed to hear the objections. Eighteen Regulations have been provisionally agreed to, most of them after some amendment; the two rules relating to switchboard galleries and passage-ways were still to be discussed yesterday, but a compromise has already been arrived at with regard to the rule as to no-voltage releases being necessary for all motors, to which, it will be remembered, there was great opposition. Apparently the objectors have not been able to obtain the entire exclusion of alternating-current motors from this Regulation, but it has been amended by the substitution of the words "every motor or group of motors" for "every motor over one-third of a horse-power," and no automatic release is made necessary when there is an attendant constantly at the controller. Apparently the Regulation as it stands is intended to apply only when there would be danger through unexpected restarting of a motor, and this was made clear by Mr. Gray when he read out his proposed amendment on Monday. An alteration made in drafting the amended Regulation on Tuesday, however, makes this point ambiguous, and the drafting will certainly need correction before it can be deemed satisfactory.

ARRANGEMENTS FOR THE WEEK

(TO-DAY), THURSDAY, MARCH 19TH.

Royal Institution.

3 p.m. Afternoon Lecture I., on "Standardisation in Various Aspects": (1) Mechanical Engineering, by Dr. R. T. Glazebrook, F.R.S.

Royal Society.

4.30 p.m. Papers to be read:—"On Secondary β-Rays." Communicated by Prof. J. Joly, F.R.S., and "On the Measurement of the Atmospheric Electric Potential Gradient and the Earth-Air Current," by C. T. R. Wilson, F.R.S.

Institution of Electrical Engineers: Leeds Local Section.

7.15 p.m. Meeting at the University. Paper to be read:—"The Rules for Electrical Installations of the German Union of Electrical Engineers," by W. P. Steinthal.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster. Paper to be read:—"New Alternate Current Instruments," by Dr. W. E. Sumpner and J. W. Record.

Dick Kerr Engineering Society.

8 p.m. Meeting at the Works. Paper to be read:—"Continuous-current High-tension Transmission," by H. J. Balcombe.

SATURDAY, MARCH 21ST.

Royal Institution.

3 p.m. Afternoon Lecture II., by Prof. J. J. Thomson, F.R.S., on "Electric Discharges through Gases."

Junior Institution of Engineers.

6.30 p.m. Reception at Caxton Hall, Westminster.

MONDAY, MARCH 23RD.

Institution of Electrical Engineers: Newcastle Local Section.

8 p.m. Meeting in the Armstrong College. Paper to be read:—"The Design and Use of Telephone and Telegraph Cables," by F. Tremain.

TUESDAY, MARCH 24TH.

Institution of Electrical Engineers: Manchester Students' Section.

7.30 p.m. Meeting at the Municipal School of Technology, Whitworth Street, Manchester. Paper to be read:—"Some Notes on Power Station Equipment and Design," by C. W. Crosbie.

Faraday Society.

8 p.m. Meeting at the Institution of Electrical Engineers, 92 Victoria Street, Westminster. Sir Oliver Lodge, F.R.S., will deliver his Presidential Address on "Some Aspects of the Work of Lord Kelvin." Lord Rayleigh will preside.

WEDNESDAY, MARCH 25TH.

Institution of Electrical Engineers: Students' Section.

7.30 p.m. Meeting at 92 Victoria Street, Westminster. Paper to be read:—"The Motor Converter," by H. W. Gregory.

THURSDAY, MARCH 26TH.

Royal Institution.

3 p.m. Afternoon Lecture II., by Dr. R. T. Glazebrook, F.R.S., on "Standardisation in Various Aspects: (2) Electrical Engineering."

Norwich Corporation v. the Norwich Electric Tramways Co., Ltd.—On Tuesday last the case of Norwich Corporation v. the Norwich Electric Tramways Co., Ltd., came before the Court of Appeal, consisting of the Lord Chief Justice, Lord Justice Farwell, and Lord Justice Kennedy, on the appeal of the Tramways Co. from a judgment of Mr. Justice Bray in favour of the Corporation. The appeal was brought for the purpose of determining the extent of the liabilities of the parties concerned as to the repair of the streets through which the company's tramways passed. The company had raised the point that the general Tramways Acts provided for the settlement of the dispute by arbitration before an official referee appointed by the Board of Trade, and the question was referred to the Hon. Alfred Lyttelton, who made an award in favour of the Corporation for a sum of £320, *plus* 5 per cent. and costs of arbitration, holding that the company were bound to keep the junction between the granite setts on which the line was laid and the road, which was maintainable by the Corporation, in a proper state of repair, and if they failed to do so the Corporation were entitled to do the work themselves, after giving statutory notice to the company, and to recover a reasonable sum therefor. Counsel contended that the Divisional Court, which upheld the award, was wrong, on the ground that the company were only bound to maintain and repair the part of the roads upon which the tram lines ran. After hearing both sides, their lordships dismissed the appeal with costs.

PARLIAMENTARY INTELLIGENCE

LONDON ELECTRIC POWER BILLS.—In the House of Commons on Tuesday, the proposal by the House of Lords, that the London and District Electricity Supply Bill, the London Electric Supply (Joint Committee) Bill, and the London (Westminster and Kensington) Electric Supply Companies Bill, be referred to a Joint Committee of both Houses of Parliament was considered.

The President of the Board of Trade (Mr. Lloyd George) said he had very reluctantly to move "That the House do disagree with the Lords in the said resolution." He did not think a Joint Committee was the best method for investigating the merits and the details of the Bills in question. He expressed no opinion upon the merits of the Bills, for everyone interested in the question knew that it was an extraordinarily difficult one. The question of the supply of electric power to London had been very prominent for several years past without any results being arrived at, and it was clear that no settlement was possible without some agreement between the parties engaged. Unfortunately the question had become a matter of political controversy, but he thought that the parties were now approaching towards a reasonable settlement. If, therefore, the Bills went to separate committees of both Houses, in the ordinary course, he thought the House of Commons might be in a position to consider the best way of coming to a decision by some general consent. He thought a conference might be arranged between the parties to endeavour to come to some agreement on the general principle, and his only object in resisting the motion for a Joint Committee was that he did not think it would facilitate the giving of a cheap supply of electricity in London.

The motion against sending the Bills to a Joint Committee was carried without a division.

HIGHGATE HILL TRAMWAYS.—The second reading of this Bill in the House of Lords has been postponed until April 2nd.

LIVERPOOL CORPORATION.—On Wednesday last week the Court of Referees in the House of Commons heard an application on behalf of the Bootle Corporation for a *locus* against the tramway clauses of the Liverpool Corporation Bill. At present the tramways in Bootle are worked by the Liverpool Corporation under an agreement, and the rent paid by Liverpool has been found to be insufficient, the deficiency having to be made up from the Bootle rates. The present Bill proposes to extend the tramways in Litherland, which, it was contended on behalf of Bootle, would bring more traffic over their tramways, and still further increase the cost of maintenance. The Bootle Corporation, therefore, asked to be allowed to oppose the extension unless the payment now made by the Liverpool Corporation for maintenance of the lines in Bootle was increased. After hearing arguments the committee refused the *locus*.

STANDING ORDERS.—The London and Windsor Motor Roads, Tram Roads,, and Tramways Bill has been declared not to comply with standing orders by the Standing Orders Committee, and cannot consequently proceed this Session.

Owing to the Standing Orders Committee having decided not to dispense with standing orders in respect of the Croydon Rural District Council's consent to the Croydon and Southern District Tramways Bill, it is probable that the whole measure will be withdrawn.

The Standing Orders Committee has decided to dispense with standing orders in respect of the consent of the Edinburgh Corporation to certain tramway proposals in the Leith Burgh Bill. The Edinburgh Corporation would only give its consent as the road authority upon certain terms which were deemed unreasonable by the Leith Corporation.

The Standing Orders Committee on Tuesday decided to dispense with Standing Orders in the case of the London United Tramways Bill, which proposes to construct a tramway over King Edward VII. Bridge, Kew, and in respect of which the consent of the local authority has not been obtained. Non-compliance had also been reported in the case of the West London, Barnes, and Richmond Tramways Bill, the promoters of which have also failed to produce the consents of local authorities. In this case the Committee dispensed with the Standing Orders, leaving it to the promoters to prove the consents of the local authorities before the Select Committee.

Postage Rates on Scientific Publications.—On Thursday last week the Postmaster-General received a deputation from the British Science Guild, headed by Mr. Verney, M.P., relative to the question of reducing the postage rates upon the publications of scientific societies and institutions. Sir Philip Magnus, M.P., said there were 300 or 400 technical institutions in this country to which the question was of the utmost importance. In his reply, the Postmaster-General said he felt it was impossible to meet the wishes of the deputation. Not only would the proposal result in considerable confusion in the sorting department, but he doubted whether the subsidising of scientific societies in this way would really benefit them. Further, it would require an Act of Parliament to sanction such special rates.

THE ELECTRICAL EXHIBITION

A CONTEMPORARY has been giving currency to a rumour, which we are happy to say is incorrect, that the Electrical Exhibition to be held in Manchester next October was to be postponed until next year. We are in a position to state that this report is without foundation.

The announcement made in our issue of March 5th, that the Manchester Corporation had agreed to permit the use of Platt's Fields for the Exhibition is absolutely accurate.

The Executive Committee held its first meeting on January 27th last at their offices, 2 Queen Anne's Gate,. S.W., and one of the most important matters then dealt with was the question of a suitable site. Mr. C. S. Northcote, general manager, and Mr. W. Davenport, organising secretary, were instructed to bring forward alternative particulars as to available land in Manchester, and these, together with plans of the proposed buildings, were considered at another well-attended meeting of the Executive Committee on February 8th at the Town Hall, Manchester. It was then announced that the Parks Committee of the City of Manchester had expressed their willingness to consider an application for the use of some spare land situated on the Platt's Fields Estate, which is immediately adjoining one of the main roads leading from the City and is in the heart of one of the most important residential districts.

The Committee, therefore, made formal application to the Corporation, and after several informal meetings they considered at a meeting on March 9th a definite offer from the Manchester Corporation for the use of Platt's Fields. The offer was unanimously accepted by the Committee. After various builders' estimates had been dealt with, based upon the plans and schemes already decided upon, it was agreed that the matter should go forward.

A general meeting is being called in Manchester on Tuesday, March 24th next, with a view to adopting the resolutions of the Sub-Committee and putting same into effect. In the meantime, draft prospectus and plans of floor space available for exhibitors are being prepared, and it will materially assist all those interested in the organisation of the scheme if would-be exhibitors will kindly advise the management as to their desire to take part in the movement, which has already received sufficient promises of support to warrant an assured success.

The scheme which is being dealt with at present is on a far larger basis than the first Electrical Exhibition, held at Olympia in 1905, and organised by the trade itself. We are informed that the total floor space of the proposed building will be approximately 100,000 square feet, so that there will be room not only for a thoroughly representative display of electrical apparatus, but also for mechanical machinery and other plant to which electricity as a motive power may be readily and successfully applied.

It is hoped that the energetic and painstaking work of the Committee will be rewarded by receiving the loyal support of the industry and trade generally.

CORRESPONDENCE

THE STANDARDISATION OF FUSES.

To the Editor of ELECTRICAL ENGINEERING.

SIR,—There are one or two misapprehensions in your Editorial comments of last week on the above Paper which we should like to correct. With regard to the ground covered by the Paper, this was not in any way dictated by the Standards Committee; the Paper was largely concerned with enclosed fuses, not because the E.S.C. were obsessed with the sinister intention of forcing rows of obese cartridge fuses into the distended jaws of consumers' distribution boards, but simply because we had dealt pretty fully with open-type fuses in our Paper on "Low-tension Thermal Cut-outs" in 1905, and because there was no published data for enclosed fuses as to the influence of fillings of various character, of the kind of metal employed, the jacket material, &c.

Your statement that various authorities prescribe 200, 100, 50, and 25 per cent. overload respectively for the fusing current of a given fuse is a strong argument in favour of standardisation; surely some definite pronouncement as to the rating of fuses would be welcome. There is also need for standardisation with regard to the method of testing, the limitation of the short-circuit current on test, &c., as the most diverse arrangements exist at the present time.

Enclosed fuses have been standardised and rendered non-interchangeable within certain limits both in Germany and America; for a detailed account of the standardisation of enclosed fuses in the latter country reference may be made to a Paper by H. O. Lacount, read before the American Institute of Electrical Engineers on September 22nd, 1905, where the necessity for standardisation is dealt with at some length. That the American standardisation has not led to an intolerable multiplicity of sizes may be gathered from a reference to the last edition of the "National Electric Code," issued by the National Board of Fire Underwriters.

We feel sure that this question may be left with confidence in the hands of the E.S.C., and trust that the results will in the future tend to lessen rather than add to the burden of the contractor, and at the same time make for increased safety and efficiency.

ALFRED SCHWARTZ.
W. H. W. JAMES.

School of Technology, Manchester,
March 16th, 1908.

To the Editor of ELECTRICAL ENGINEERING.

SIR.—I am strongly inclined to agree with your leading article of last week. It seems to me that what is wanted is standardisation of fuse-boards, not of fuses.

I attended the meeting at which Prof. Schwartz's Paper was read, but the time allowed for discussion was too short. The main point is that we require a metal or alloy that will not "splash." Copper seems to meet this requirement best, but, as Mr. Mordey pointed out, it is not possible to get wire of sufficiently small section with sufficient strength, and it is affected by heating. This was my own experience years ago. The "splashing" effect of the usual lead and tin fuse is a serious matter when highly inflammable material is about, and I have had experience of more than one fire from this cause. It is especially dangerous in motor garages, where petrol is often carelessly exposed. I find that fuse-boards which have been in use for any length of time are plentifully provided inside the case with fused metal.

As regards rating of fuses, I am of opinion that this can safely be left to the good sense of the contractor installing or maintaining an installation, and I have very little to complain of on this score. My own practice

Digitized by Google

is to allow an overload of 50 per cent., and this I find works well generally, but one, of course, has to be guided by circumstances. The margin should be increased in the case of hotels and public buildings and places where it is desirable that the lighting should not be cut off unless really necessary.

I do not favour the enclosed type of fuse, and prefer a type that is always in view. The attendant can then readily see which fuse has blown, and replace it. Another advantage is that one soon gets familiar with the size of wire necessary for various circuits, and a very fair judgment can be made. I remember that many years ago Mr. Arthur C. Cockburn read a Paper before the Society of Telegraph Engineers, which was on very similar lines to that recently prepared by Prof. Schwartz. This Paper seems to have been quite forgotten. Mr. Cockburn advocated, I think, a fuse provided in the centre with a weight, which quickly separated the metal when it fused, and got rid of the "splashing" effect. I believe this type of fuse was used a good deal, but it seems to have dropped out for some reason. To my mind it would be of far more importance if the various makers could be persuaded to standardise their boards. In all my specifications I have to go carefully into details and to get prints, &c., and this should not be necessary.

With the present type of board I find there is a tendency for the small binding screws to loosen and the contacts to open, and this especially in buildings over railways, where more than ordinary vibration is experienced. To this cause I put down the arcing that frequently occurs between the live metal on the board and the enclosing case (when of iron): it is very difficult to get makers to realise the necessity of allowing plenty of space between the bases and the case. Lining with asbestos is not of much use, as this material is hygroscopic, and is generally fastened with metal clamps, which also causes arcing. The contacts, too, are often so close together that on circuits of 200 volts and over, if one fuse blows it sometimes blows the lot. I have often either to reject boards at the last moment, or to put up with these defects, and I know that this is not my experience alone.

In many installations under my care I have to make careful periodical inspections to see that binding screws, &c., and contacts are in good order, and this should not be really necessary.

In my experience quite 80 per cent. of blow-outs are caused at the board, and not in the line. My experience of fuses is generally unsatisfactory; when they ought to blow they don't; and when they do, the cause cannot be ascertained. I quite follow your remarks about the unsightliness of boards, if different sizes of cartridge fuses were fitted. The boards are already sufficiently ugly, and one of my clients always refers to those in his house as "torpedo boat" fittings.

S. G. C. Russell.

March 16th, 1908.

A.C. MOTOR-STARTING SWITCHES WITH NO-VOLTAGE RELEASE.

To the Editor of Electrical Engineering.

Sir,—With reference to the inquiry which is being held relating to the rules which the Home Office propose issuing regarding the use of no-voltage release switches, we are exceedingly surprised to see from the evidence reported in the technical Press, given by many of the leading engineers, that they are not aware that switches of this type for use with alternate-current motors have been on the market for the past 18 months, and that, furthermore, a great number have been installed in various mills, collieries, &c., more especially in the north, in fact, in the more recent specifications issued by at least one of the leading firms of consulting engineers in Manchester this type of switch is specified.

We have made a speciality of the manufacture of these for the past 18 months, and have supplied switches for controlling over 17,000 h.p. of three-phase motors, and have on order at the present time switches for controlling an additional 5,500 h.p. We enclose a copy of our catalogue relating to these switches, and from which you will see that we are manufacturing them in four standard sizes for 15, 50, 200, and 500 amps. per phase, suitable for mounting on switch panels, or we supply them fitted in protected iron cases or in gas- and water-tight cases as required. From the prices given you will see that the cost of installing switches having this no-voltage feature is not very much in excess of that of installing ordinary high-class cast-iron case switches.

Furthermore, as these switches are of the remote control type operated by a separate small switch, the main switch can be mounted close to the motor which it controls, the operating switch being placed in any convenient position. This frequently leads to a considerable saving in the cost of the three-core connecting cables, and in certain instances we have been able to show that it was cheaper to fit switches of our no-voltage-release type instead of switches of the ordinary ironclad pattern. In addition, there is the advantage that all our switches are of the oil-break type, with quick make and break action.

We must apologise for taking up so much of your space with this letter, but we think that, in view of the evidence which was given at the afore-mentioned inquiry, this matter is of interest to the majority of electrical engineers in this country.

Eckstein, Heap & Co.

Waverley Mills, St. Simon Street, Salford.

THE FUTURE OF THE TELEPHONE SERVICE.

To the Editor of Electrical Engineering.

Sir,—In your issue of March 12th, you insert a long letter on this subject from the pen of Mr. Herbert Laws Webb, who occupies the distinguished position of chief of the Contract Department of the National Telephone Company. Mr. Webb, as he has often done before, prescribes certain remedies for the telephone evils which are so strongly complained of, and he naturally advocates suppression of the flat rate tariff and the substitution of measured rates. Such a change, as calculated to extract the greatest amount of money from the pockets of telephone users, naturally suits his—*i.e.*, the company's—standpoint, but then the company's and the subscribers' interests are not identical. No amount of special pleading—and Mr. Webb's pleading is very special—can cover up the fact that those municipalities which instituted telephone systems of their own have demonstrated that a good, trustworthy telephone service, satisfactory to the subscribers, can be maintained with profit by giving telephone users the choice of a flat rate, which in different places has varied from £5 to £6 6s. per annum, and of a measured rate of £3 per annum and a 1d. for each call. No settlement of the telephone question should be entertained that does not give British users these terms. The new Post Office rates are simply outrageous. The lowest is £5 for 500 calls, and the smallest user must pay that, although he may only require to originate 50 or 100 calls per annum. In the first case he would pay, under the municipal system, £3 4s. 2d., and in the second £3 8s. 4d., as against the Post Office £5 minimum. All this could be proved before a Select Committee if the Post Office would consent to one being appointed; but they, like their colleagues of the Contract Department of the National Telephone Company, are too intent on squeezing the last penny out of the user. The Chambers of Commerce have taken up the question very energetically of late, but, personally, I do not think that anything short of a full thrashing out of the matter before a Parliamentary Committee will produce any tangible result.

I am, sir, yours, &c.,

A. R. Bennett.

Queen Anne's Chambers, Westminster, London, S.W.
March 16th, 1908.

[Mr. Bennett is not correct in designating Mr. Webb chief of the Contract Department of the National Telephone Co.—Ed. E.E.]

Royal Society.—Among the list of names of candidates selected by the Council of the Royal Society at their annual meeting for election as Fellows in May next we notice that of Mr. Dugald Clerk, who is well known in connection with researches on the thermodynamics and action of the internal combustion engine, subjects upon which he has worked at for the last thirty years, and written a large number of papers. He is at the present time a director of the National Gas Engine Co., and has also an extensive practice, both as a consulting engineer and as a patent expert. He will be the president of the Engineering Section of the British Association at the Dublin meeting this summer, and is also president of the recently-formed Institution of Automobile Engineers.

ARTIFICIAL LOAD FOR TESTING ELECTRICAL GENERATORS

THE paper on the above subject by Messrs. R. K. Morcom and D. K. Morris, read on Wednesday of last week before the Birmingham Local Section of the Institution of Electrical Engineers, commenced with a consideration of water resistance, and pointed out the great differences in the conductivity of water obtained from different sources. Distilled water, for example, has a specific resistance of 600,000 ohms per cubic centimetre at 60° F., while the corresponding figure for Birmingham "tap" water is 13,200, and for Birmingham canal water only 435.

In an actual test tank, gradual solution of the metal electrodes causes a fall of resistance beyond that due to temperature, because the higher the temperature with a given current the less the amount of cooling water to dilute the iron solution. For a rise of temperature of 70°, approximately, 50 gallons of cooling water per kilowatt-hour are required. Where possible salt or soda should not be used to increase the conductivity, but the plant should be designed to use the most abundant local supply. A very large body of water cannot give a high resistance even when the electrodes are very far apart, and if the tank be long in proportion to its cross-sectional dimensions the extent of the electrode immersion makes very little difference to the resistance, provided that the area of the electrode is not very small compared with the cross-sectional dimensions of the water. If, however, the distance between the plates be small, then their area of opposition has a great influence on the resistance. Proximity to the side of the tank has a great effect with narrow plates in large tanks, due to distortion of the lines of flow. Part of the distortion is equivalent to shielding the back and sides of the plate. This effect gives one means of varying the load.

Another convenient method of reducing the load from a given tank is by dropping diaphragms between the plates. Various modifications of the baffle method will suggest themselves by which the resistance of the path may be increased without upsetting the cooling arrangements or complicating the tank, but the possibility of charring by excessive voltage drop in a short length must be kept in mind. The proximity of the plates to the side of the tank is also a factor in the permissible volt drop per foot of water.

It is found that where the line of flow from the electrode along the tank-side differs but little in length from the shortest line, the voltage drop per foot should not exceed 600 volts, and should be lower than that unless the walls are well insulated and free from metal. This point must be watched with high-tension work, and also in low-tension work where plates that are close together are carried near the side of the tank. A further limiting condition indicated by experience is the maximum permissible current density per square inch of an iron electrode. It will be found advisable not to run at greater densities than 1 ampere per square inch. Trouble from bubbling and rapid corrosion is likely to occur if this be exceeded.

With regard to the materials to be chosen. Wooden tanks are cheap and easy to obtain; they can, with proper precautions, be made durable and water-tight, and, as the sides can be rendered practically non-conducting, there is no difficulty in obtaining light loads. Metal tanks, on the other hand, are either expensive or perishable, and light loads are hard to obtain owing to the low resistance path afforded by the walls, unless unduly large tanks are used. Cast-iron electrodes are cheap and satisfactory, though scrap metal of various sorts may in certain cases be substituted for sake of convenience.

The following is a description of a tank which has done excellent service:—

The dimensions are 7 ft. × 1 ft. 6 in. × 1 ft., and it is used for high-tension work. The sides and bottom are constructed of good spruce, tongued and grooved; all joints are tarred and caulked. Sides, ends, and bottom are made double of 1½-in. timber, the two layers being built up at right angles. The whole is screwed together in such a way that no screw comes within ¾ in. of the water, and all timber is tarred all over. The water inlet is through a canvas hose brought over at the outlet end, and carried along the bottom of the tank for its full length. The outlet is over a sectional wire 6 in. from the end of the tank, and then through a hole in the bottom of the tank. One trouble thus avoided is the charring of the wood, which usually occurs along seams to which water has access: proper caulking prevents this. Also, any metal in the wood to which water has access corrodes and causes charring. This is prevented by using hidden screws, a hose pipe inlet, and a plain hole outlet. The hose pipe inlet obviates troublesome short circuits to earth, and the weir also provides for adjustment of water level. The double sides prevent leaking and undue bulging. For tanks of larger dimensions iron stays may be used, but these should be carried outside the tank, an obvious but often neglected precaution.

As this tank is for high-voltage work it is supported on insulating pedestals. These can conveniently be constructed of Doulton's glazed earthenware "acid tiles," built about 3 ft. high, with a rubber pad between each horizontal face to prevent slipping. The water from the outlet hole is carried to a funnel or tray just above the floor level. A lead-lined saveall is provided. The operator has a wooden platform supported on earthenware blocks, and covered by a rubber mat. The electrodes are of iron, and are well insulated from their supports, which take the form of stout wooden cross-bars which can be slid along the tank top. The plates are clipped to busbars carried at a considerable height, and the connections are so guided as to be neat and safe. Such an arrangement can be cheaply made, and gives satisfaction up to 6,000 volts.

A low-voltage tank construction can easily be deduced from the above, but probably the area will have to be obtained by using a number of electrodes in parallel, in which case, for variable loads, a suitably arranged switchboard is a great convenience. One point should not be forgotten with iron electrodes, namely, that if they are placed less than 2 in. apart there is danger of an unsteady load, and a considerable splutter from short-circuiting by rust flakes; in fact, 3 in. should be aimed at as a minimum. Sometimes, for very low-voltage work, the size of the tank available is insufficient. A useful form of load can then be constructed from metal strip submerged in water.

Strip iron ½ in. wide × 19 S.W.G. supplied in 40 ft. lengths and doubled into zigzag shape will make very convenient units for low-voltage loads. With a current density of about 25,000 amperes per square inch (the unit being immersed in moderately high resistance water) an average life of 100 hours may be expected. If, however, the cooling water is of relatively low resistance, such as canal or river water, the life is very much reduced. In actual use a unit of this form has been run at a current density in the iron winding of 52,000 amperes per square inch in canal water of a specific resistance of 440 ohms per cm.³ at 60° F., and broke down after an eight hours' run. Under these conditions the rapid wasting of the strip caused a gradually falling load. It is very convenient, when using these units, to have a small water load in parallel for fine adjustments. Obviously the relatively short life and lack of facility of adjustment are the chief disadvantages of this form of load.

The convenience of the water resistance for absorbing a test load can be enhanced by providing a suitable apparatus for producing inductive load. Choking coils for this purpose have hitherto been constructed by placing a suitable winding on an iron core having a small and sometimes adjustable air-gap. The object of the air-gap has been to render the out-of-phase magnetising current as large as possible. In the choking coils to be described below no air-gap at all is used, but the iron is instead worked at a flux density so high that its permeability is quite low, and the magnetising current is correspondingly large. As compared with ordinary choking coils, this construction has two distinct advantages. The flux density can be very much greater than is practicable with the older coils (three to four times). The induced voltage per turn is, therefore, correspondingly increased, and the necessary number of turns reduced. Also the magnetic reluctance is so uniformly distributed all round the magnetic circuit that the magnetic leakage is very small, and every turn of the winding is equally utilised.

On account of the high flux density it is important, in order to avoid eddy currents, to use the thinnest laminations and to reduce hysteresis by employing the best iron. As is well known, heavy iron cores cannot be worked at 50 cycles for long at flux densities exceeding, say, 8,000, without very special means being taken for cooling them, and at the flux densities which are being used in these new coils described in the Paper, such cooling is an essential condition. Cooling the core is not that the iron itself may be rendered cool, but that it shall not impart too much heat to the windings which surround it. The loss in the iron itself is, in fact, very substantially reduced by a rise of temperature of the core, partly on account of the reduced hysteresis, but much more by the increased resistance of the iron and consequent reduction of the eddy current loss, which, in cores worked at very high flux densities, is otherwise disproportionately large.

Two methods suggest themselves for working such high flux density choking coils continuously without overheating. The whole coil and winding may be immersed in water kept in circulation and slowly flowing to waste. The limbs of the iron core may be surrounded by coils of flat copper tube, closely fitting, in which water is continually flowing.

Digitized by Google

In cases where the voltage permits it, there is great advantage in the first method. Not only does it provide a satisfactory means of getting rid of the heat in the core, but it allows of the use of very high flux densities in the winding. Copper for the windings may even be dispensed with altogether, and the coil wound with iron strip worked at current densities which would be high even for copper if not specially cooled. Such coils are in the highest degree economical to construct and prove perfectly

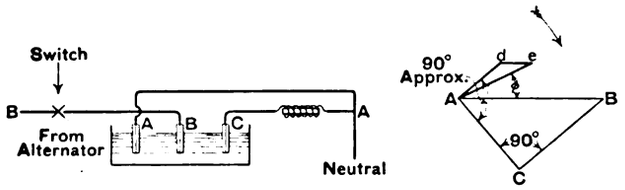

FIG. 1.—COMBINED WATER LOAD AND INDUCTIVE LOAD.

satisfactory if the voltage does not exceed 1,000–2,000. For voltages much higher than these, or where a more durable apparatus is necessary, it is preferable to use water-cooled cores of the type described above.

To test a 1,000-kw. set at 0·8 power factor requires approximately 1,250 kilovolt-amperes, and 750 kilovolt-amperes of idle current, or three 250 kilovolt-amperes choking coils. With the special cooling described above, these inductive coils can be constructed on cores not exceeding in size those which would be used for three 25-kw. transformers.

Exceedingly low power factors can be obtained with this apparatus ranging down to that representing a lag of about 89° in the larger sizes. The lower the power factor the less the energy which has to be got rid of in the inductive coils, and consequently the higher the figure at which such coils may be rated. The relation between impressed terminal voltage and current (r.m.s.) taken by the coils, depends upon the magnetisation curve of the iron used in the core, as well as on the wave-form of the current itself. At high flux densities a relatively small drop in voltage reduces the current almost to nothing. It is characteristic, therefore, of these choking coils, that while they work well over a wide range of current, yet their range of voltage is small.

It is not practicable to have special inductive loads made for every voltage and current of the machines which may have to be tested. It is therefore of the greatest importance to provide means whereby the voltage as well as the current of an inductive load may be regulated while the power factor is maintained at a specified value of, say, 0·8. The most satisfactory method of arranging for such regulation is by means of water resistance arranged in such a manner that the inductive coil current is shunted by an in-phase component of current in a water load, while, at the same time, resistance may be put in series with the choking coil (see Fig. 1). By shifting the plate B towards A or C, the double adjustment may be conveniently effected at one time. Adjustment is also obtained by raising or lowering one or more of the plates. The inductive coil may be either immersed in the tank, or may be in a separate place according to the method used.

Further variations of voltage and current may be obtained by the well-known methods of paralleling the coils, or changing from star to mesh connection or both, used always in conjunction with the above combination of water loads. Since the change from star to mesh coupling reduces the voltage for which the inductive set is suitable and increases the current by $\sqrt{3}$, it is convenient to make the next step down in voltage correspond to the paralleling of three equal sections of the winding, since this will again give a step $= \sqrt{3}$. The next step, again, would then be by changing from star to mesh, the coils remaining still in parallel. In this way an extreme range of voltage of as much as 9 : 1 may be obtained with a three-phase set, each of whose windings is subdivided into three parts only, while throughout this range the set can be worked, if required, at constant kilovolt-amperes and core flux density. For testing at reduced loads the correspondingly smaller kilovolt-amperes are obtained by working the cores slightly at lower flux density. For economy in design it is best to use choking coils wound for the lowest voltage, which will satisfy the purpose for which the coils are required. If they are wanted for testing three-phase generators at a moderate power factor, it will be found that the necessary coil-voltage is not more than one-third to one-half of the terminal voltage of the machine under test.

To extend the range of the set the sections of the combined load may be coupled in mesh or delta connection. In this way the current capacity is increased as $1 : \sqrt{3}$, while the voltage limits are correspondingly reduced. To deal with yet lower voltages and higher currents, it is convenient to subdivide the windings on the coils each into three sections as described above. These, when paralleled and star-coupled, give a set of volt-ranges one-third of those first available, and consequently reduced as $\sqrt{3} : 1$ from the second arrangement in which the apparatus was delta-connected and all the windings on each core were in series. Lower voltages still can, of course, be obtained by delta-coupling the third arrangement; and, if advisable, by further subdivision of the coils. The combination of coils and water-loads described here is thus of a very flexible nature, and well suited to deal with the variety of generators which may have to be tested commercially.

The kilovolt-amperes of an inductive load being fixed, the winding must be so chosen that the following conditions are satisfied: (*a*) It must carry the required current without undue heating continuously, or, in special cases, for a given short period; (*b*) its number of turns must be such that, when carrying this current, a back E.M.F. equal to the required terminal voltage is obtained; and (*c*) there must at the same time be enough ampere-turns operating on the coil's magnetic circuit that the requisite high flux density is obtained. If the coil is above a very small size, and not required for short-time rating only, the core must be cooled.

The use of these coils worked at such high flux densities gives rise to a current-wave whose peak is about 10 per cent. higher than that of an equivalent sine-wave of current. That is, in calculating the ampere-turns available for producing the maximum of flux density the r.m.s. ampere-turns must be multiplied by about 1·56; so that the value of H is about 1·96 × the r.m.s. ampere-turns. The approximate field is therefore roughly obtained by doubling the r.m.s. ampere-turns. The distortion of wave-form is, however, not very great owing to the very high flux density, and therefore uniformly low permeability, which occurs.

The most suitable design of choking coil is in many cases that giving the *least power factor*. This factor is the ratio of copper and iron losses to the total kilovolt-amperes of the choking coil.

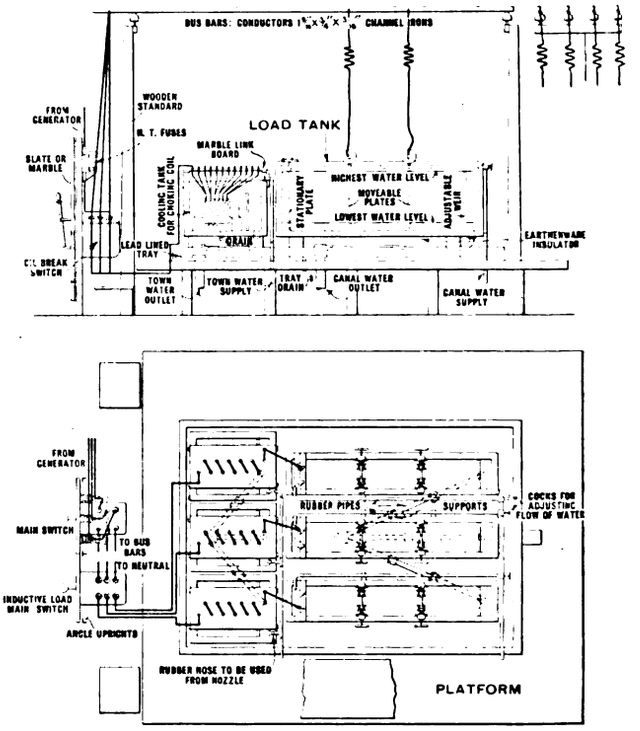

FIG. 2.—SUGGESTED DESIGN FOR ARTIFICIAL LOAD, INDUCTIVE AND NON-INDUCTIVE, SUITABLE FOR 1,000 K.W. AT 1,000 TO 6,000 VOLTS.

The losses depend on the square of the current and on some similar function of a not widely varying flux density, while the kilovolt-amperes are proportional to current and flux density. Thus there will be a point at which the power factor is a minimum which occurs at a higher flux density the larger the coil.

It is difficult to generalise as to the best method of combining the details, but the authors append a suggestion for a working

Digitized by Google

plant on lines which have been found very satisfactory in practice over a large range of conditions (see Fig. 2). The inductive coils here shown are cooled by immersion in suitable tanks in which water is circulated, as also in the main load tanks by a system of pipes clearly indicated.

DISCUSSION.

Mr. J. P. KEMP (Birmingham) said that for high-voltage tests he had found a water load to be the only suitable form where large amounts of energy had to be dissipated. With wooden tanks, however, he had experienced trouble, the troughs had caught on fire, and the water leaked out. In Manchester, at the Stuart Street Station, he had used for three-phase, 6,500 volt work, a circular iron tank 6 ft. in diameter and 4 ft. deep, with the outer electrodes symmetrically spaced at 120 degrees, and about 7 in. away from the neutral element. The water was introduced in the centre at the bottom of the tank, and flowed away over a weir at the top. With this particular tank 4,000 kw. had been successfully absorbed for over six hours. The outer body of the tank also formed part of the neutral element, and as this was substantially earthed there was no possible danger from shock. With wooden tanks, however, there was considerable risk of men receiving a shock from the body of the tank or even from the water. As a permanent adjunct to a central station, a suitable water load was very desirable, for it enabled one to perform various adjustments to valves, governors, &c., and there was no question about its advantage and superiority over the temporary arrangements frequently provided for official tests. The main point of interest in connection with the Paper was the method devised for obtaining loads of varied power factor Up to the present, although a variety of inductive load tests were often called for in specifications, he did not know of any case in which they had actually been carried out.

Mr. J. M. WALSHE (Birmingham), referring to Mr. Kemp's description of the circular metal tank, said that it would be quite impossible to use this with Birmingham canal water at 6,000 volts, as the maximum load would be too great. With low resistance water, it was necessary to have a long narrow tank. Three tanks each 6 ft. long, 1 ft. deep, and 6 in. wide, had been found quite large enough for 950 kw. at 7,500 volts, and the load could be reduced to 40 kw. at the same voltage. This range would not be possible with metal tanks using canal water. A point in connection with the use of small tanks is that the water supply must be reliable and regular, as owing to the decrease of resistance with the rise of temperature of the water there would be danger of a heavy overload if the supply were to fail. With tanks of small capacity the rise of temperature is very rapid. An open drain should be fitted under the weir, so that in case of a failure of the water supply, the level of water in the tank would fall, and the resistance of the water remain about constant.

Mr. KEMP here explained that he quite agreed with Mr. Walshe that it was impossible to use canal water in small metal tanks for 6,000 volt tests. In the tests to which he had previously referred, he had used town's water; under these conditions he had found it possible to vary the load from 40 to 4,000 kw., simply by varying the immersed area of the electrodes, the amount of water remaining constant; as a precaution against failure of the water supply and the consequent increase of load he had used a drain pipe at the bottom of the tank; the amount of load on the tank was, however, under perfect control, and could be readily adjusted by means of a small motor operated from the switchboard.

Mr. R. A. CHATTOCK (Chief Electrical Engineer, Birmingham Corporation) said that the authors had stated that the voltage drop per foot of water should not exceed 600. If this applied to low-tension current, he thought it a very low figure. He considered that the limit of current density of one ampere per square inch of plate was too high. In stationary water boiling would occur in a very short time with probably ½ ampere per square inch. He recalled some tests in which he had used two plates placed in a canal. The conditions were 100 kw. load at 1,000 volts single-phase alternating current, the electrodes were 15 ft. apart, the immersed area of each being 10 square feet. One could feel the effect of the electric current at least 50 ft. away, and fish were killed within a radius of 20 ft. As a danger signal, whilst the test was going on, a small raft was moored between the electrodes, from which two iron plates were suspended in the water 18 in. apart; a 100-volt lamp was connected to these plates, and the drop in pressure was sufficient to light this up He had tried a single-phase test with a metal tank as one pole, and a rod in the centre of the tank as the other, and the result was practically a short circuit. Using the same tank and two rods, one for each pole, gave quite satisfactory results. He had had trouble with wooden tanks owing to deterioration of the wood allowing the water to leak and causing charring on the outside; he had also known the wood to catch fire if this was allowed to go on.

Mr. F. FORREST (Birmingham) thought that in the design of tank with sliding electrodes, some mechanical means of adjustment was desirable. He wondered that no serious attempt had yet been made to utilise the power wasted in works test rooms, and suggested that it might be possible by using a system of storage cells and a wide range booster. It might also be possible to utilise the hot water from the testing tank to feed the boilers.

Mr. J. D. COALES (Birmingham) referred to the form of wave obtained with choking coil employing high flux densities as described, and suggested that when an alternator was tested on such an inductive load, the "drop" might be exaggerated unfairly, owing to the concentration of the demagnetising reaction with a small part of the cycle where it was most effective.

Dr. W. E. SUMPNER (Birmingham) said that the Paper was clearly divided into two distinct parts, a practical portion dealing with water loads and tank construction, and a more theoretical portion bringing forward a new feature in connection with the design and construction of a load suitable for taking current at a given power factor. The novelty consisted of using a choking coil with a closed iron magnetic circuit and working it at very high flux densities. The current wave in a transformer having a closed magnetic circuit consisted of a shoulder and a peak. At very high flux densities the peak would be increased, while the shoulder would be less pronounced. This would result in a zig-zag wave of current very like a series of triangles. A sine wave was approximately a triangle with the peak rounded off, so that the resulting wave would essentially differ only very slightly from a sine curve. The use of these choking coils would thus have no unusual effect on the alternator.

Mr. N. B. ROSHER asked if the authors had fully considered the use of wire resistances. He had had experience with these years ago, and had found them to work well. They could be mounted on frames in units, and were very convenient for connecting up to test-room terminals. One advantage was that they could be used for testing generators after final erection, as a sufficient number of resistance units could easily be sent out from the works for the purpose.

Mr. A. E. GOTT was particularly interested in the portion of the Paper dealing with water resistances. As an illustration of the high resistance of pure country water, he mentioned an experiment made, previous to a dissipation test, on an ordinary oil barrel filled with water. Lead plates were used, each with two square feet immersion. When brought to within only three-quarters of an inch of each other, 100 volts only gave 2 to 3 amps. The addition of two or three ozs. of acid enabled him to dissipate 60 h.p., with the plates a safer distance apart. He gave the capacity of a barrel as 20 h.p. for one hour before boiling. He advocated water cooled open wire resistances. In his opinion, insulated water tanks would not be tolerated under the new Board of Trade regulations, a point which seemed to have been overlooked in the Paper.

Prof. GISBERT KAPP (Birmingham University), referring to the question of insulation, said that it was not sufficient to earth the tank. It was not possible to get a better earth than canal water, and yet it was possible to get a shock from the water. The tank itself should be earthed, but surrounded by a platform supported on insulators and covered with a rubber mat. He would like to ask whether the authors had had any experience with earthenware, which appeared to possess the advantages of both wood and metal tanks with the drawbacks of neither. He had found them to work very well for small loads. He would also like to ask the authors if they had observed the actual power factor of a resistance consisting of iron plates in water. He believed that this was not quite unity, but that the water load took a leading current. Electrolysis was continually going on and producing a film of gas on the plates, and thus forming a condenser.

Mr. R. K. MORCOM, in reply, said that one of the criticisms on the water resistance had been that it was possible to take a shock from the water. He had never experienced any trouble of this kind. The necessary precautions were quite simple. There were objections to using the hot testing water in boilers. Ordinary canal water would require to be softened before it could be used in this way, and by the time it had passed through the water softeners it would have lost a great deal of heat. If the water were softened previously it would not be so suitable for testing, and any lost waste would be expensive on account of the chemicals used. He had carefully considered the question of utilising the power usually wasted in the test room. But there were many difficulties in the way. Tests were carried out, using all sorts of pressures and currents and at odd times. Mr. Chattock said that he had trouble owing to the liability of wooden tanks to fire. Previous to this, Mr. Chattock had expressed the opinion that a drop of 600 volts per ft. was not so much as might be employed. In his experience it was only by using a moderate drop per ft. of water that it was possible to avoid charring the wood of the tank. The objection to porcelain tanks, of which Prof. Kapp had spoken, was mainly that of expense. Prof. Kapp had suggested that a water resistance acted like a capacity. In their tests they had noticed this, as they found it necessary to use a small amount of induction in conjunction with the water load in order to get unity power factor, but he had not attached much importance to this, as the accuracy of the readings had been questioned. He did not believe that the

Digitized by Google

factory inspectors would take exception to the insulated tank. They really had a very good earth in the overflow water flowing into the canal.

Mr. D. K. Morris thanked the audience for their interest in the Paper. Mr. Coales had drawn attention to the wave form of the current taken from the alternator by a choking coil of their new type, and had suggested that this was of an unusual shape Dr. Sumpner had explained how this did not mean a wave differing materially from a sine wave. It was of great importance that the inductive load did not produce a different kind of load from that occurring in practice. Considering that only 3 or 4 per cent. of the current wave was sufficient to bring the flux over the knee of the saturation curve, it would be seen that practically the whole of the current wave corresponded to the region of low permeability, where, as was well known, the variations of permeability were not great. Thus the current wave was not far from being such that its rate of change was a copy of the volt wave, and the reactions in the generator for which the test was being carried out were therefore entirely normal. A slight distortion of wave shape was, however, quite proper in such tests, for this would occur in practice when a load of bad power factor arose.

TRANSATLANTIC WIRELESS TELEGRAPHY

At the Royal Institution last Friday a very crowded audience listened sympathetically to the story of the Marconi Company's Transatlantic service of wireless telegraphy. The lecturer, Mr. G. Marconi, sketched the history of the past six years, beginning with the erection of the Poldhu station and the reception of the first Transatlantic signals in December, 1901. This feat, it is well known, was accomplished by aid of a kite air-wire and coherer; the lecturer now divulged that the wave-length was 1,200 ft., that the power at Poldhu was 15 kw., that the spark length was about an inch and a half, and that the discharge capacity was one-fiftieth of a microfarad. The following year saw the erection of a large station at Glace Bay, Nova Scotia, and, also, many alterations at Poldhu, the wave-length, for example, being raised to 2,600 ft. In December, 1902, Glace Bay transmitted to Poldhu easily, but the signals from Poldhu were too weak for communication.

The Cape Cod station shortly afterwards got also into touch with Poldhu, sometimes using no more power than 10 kw. The *Times* Press messages in the spring of 1903 proved a failure on account of insulation breakdowns at Glace Bay, followed by a series of miscellaneous accidents. The experiments inaugurated in connection with the repairs led to many important improvements, so that in the end new stations were planned on each side of the Atlantic. Some of these experiments had to do with the aerials, which at these large power-stations are enormous structures. For instance, it was found that by adding wing-like wire extensions to the Poldhu inverted pyramid aerial, good signals could be transmitted 550 miles (to Fraserburgh) with a power of only one kilowatt, the wave-length being 14,000 ft. It is to be noted that waves of great length and small amplitude carry best; such waves seem to be less strongly absorbed by ionised air than shorter waves of greater intensity. The new stations that were erected in consequence of these and other experiments were situated at Clifden, Ireland, and at Glace Bay. The Glace Bay new station had a large aerial 220 ft. high extended horizontally by 200 wires 1,000 ft. long at a height of 180 ft. The wave-length was designed for 12,000 ft., and the sending capacity was 1·8 microfarad, the spark-length being $\frac{3}{4}$ in. Signals were received at Poldhu day and night throughout the spring of 1905. The signals were faint, and were only one way. To improve the signals new directive aerials were planned for both the new large stations—that is, the horizontal extension of the main vertical air-wire system was concentrated in the direction pointing away from the station to be communicated with. Another improvement was the substitution of an air-condenser for the glass condenser hitherto used. This avoided the losses due to dielectric hysteresis, as well as reduced the expense of repairs to dielectric punctures, though, of course, the condenser becomes of gigantic proportions. At the end of May, 1907, the Clifden station was finished. Its wave-length was 12,000 ft., and its capacity of 1·6 microfarad was charged to 80,000 volts. Good signals were exchanged with Cape Breton from the very first. At this period experiments were proceeding at Poldhu with new and powerful apparatus for generating continuous or semi-continuous electrical oscillations. These trials showed so great an improvement over the existing spark apparatus that it was decided to instal sets at Clifden and at Glace Bay. The new apparatus consists of a metal disc capable of rotation on high speed, nearly touched by two spheres or discharge balls, one on either side of the disc near its periphery. The disc and each ball are severally connected to a condenser having a self-induction coil in series with it. These three oscillatory circuits are connected together at the free ends. A high-tension continuous-current supply is introduced into these circuits at the two spark balls. Oscillations occur in the principal circuit—that is to say, the condenser and inductance connected to the disc, whenever a spark passes from either ball to the disc. If the disc were stationary, a flaring arc forms, and no oscillations are produced, but if the disc is in rapid motion, the formation of an arc is made impossible. The discharge is thus neither the mere oscillatory spark nor the arc. Efficient cooling of the metal parts is necessary, and the inductances in the various branches should be equal. Frequencies as high as 200,000 per second are easily reached. A disadvantage of producing perfectly continuous oscillations is that some method of interrupting the received waves is necessary at the receiving end to make the signals legible. The machine just described lends itself excellently, on the other hand, to the production of regularly broken streams of oscillations. A form now in use possesses a disc having a large number of knobs near the periphery at each side of the disc. The sparks on each side take place, of course, at the knobs. The result is that a signal dash is heard in receiving instruments as a sustained, clear, musical note. One great advantage of this is that the note enables the receiving operator to exercise now a discrimination between atmospheric discharges and true signals such as was never before possible. The lecturer, pasing to the story of the actual performance of these great stations, stated that from the date (October 17th, 1907) of establishment of a commercial service, the transoceanic intercommunication have never been interrupted for more than a few hours. Long interruptions had occurred in the land-line services—one, for instance, of 17 hours at Clifden. Snow had caused many delays at the Canadian end by breaking land-lines, but the aerial wires of a "wireless" station afford no footing for snow, because slightly warmed by the oscillatory currents, and thus have suffered nothing. Transmission was at first slow, but is now quicker, and in a few months duplicate and improved plant will be installed, such as will enable rapid sending to become the rule, and will enable the full power of the mechanical plant already in position to be brought into play. The messages are sent by day as well as by night. There are bad periods, of course. In the morning or in the evening, when the part of the atmosphere traversed is only partially illuminated, the signals may become weak or even disappear. Perhaps this is due to reflection or refraction of the waves at the boundary between illuminated and non-illuminated air. If all the space is illuminated or all is dark, signals are, as a rule, good. Thus it is probable that the morning and evening bad periods would not be noticeable in transmission from north to south or *vice versâ*. Signals are sometimes weakened by the intervention between the stations of storm areas. On the other hand, the signals are abnormally strong on some nights. The lecturer here commented on the animosity shown by certain sections of the technical press towards his efforts to establish successful Transatlantic wireless telegraphy. They appeared to exist, he said, not for encouraging all electrical advances, but for protecting the interests of the cable companies; their outbursts would prove very amusing reading some ten years hence. In conclusion, he thought wireless telegraphy would provide a cheaper transoceanic service than cable, but whether a better or worse one remained to be seen.

The New Telephone Charges.—In accordance with his promise a short time ago, the Postmaster-General on Wednesday last week, received a special deputation from the north of England, on the subject of the new telephone rates. The proceedings were private, and were carried through in a more or less informal conversational manner. The Postmaster-General was accompanied by Mr. H. Babington Smith, Secretary of the Post Office, Sir R. Hunter, Solicitor to the Post Office, and Mr. A. M. J. Ogilvie, of the telephone department. Representatives were present from the Chambers of Commerce at Manchester, Sheffield, Newcastle, Glasgow, Bradford, and Birmingham.

Workmen's Compensation.—Before Judge Shiress Will, K.C., in the Salford County Court last week, two cases of workmen's compensation were heard at the instance of the British Westinghouse Electric & Manufacturing Co. It appears that in both cases the employee had been injured whilst working on the company's premises at Trafford Park, and awards of £1 per week had been made. The company, however, had since found the employees in question light employment at a wage of £1, and the applications were now made to reduce the amount of the award for injuries. After hearing arguments, the judge reduced the compensation in one instance to 10s. per week, and in the other to 10s. 9d. per week, giving leave for the men to apply to the Court should the company cease to afford them light employment.

ELECTRIC LIFTS

A PAPER dealing with the subject of electric lifts was read on March 11th by Mr. H. D. Wilkinson before the Association of Engineers-in-Charge at the St. Bride's Institute, London. The electric lift, the author said, is not a cheap machine as regards capital cost, but it possesses advantages in control, simplicity of working, lowness of running costs, and safety. It is now almost rare to find a new passenger lift put in with cage rope control, this type of control being almost entirely confined to goods lifts. The cage switch method of control has come in almost supremely for passenger lifts. Indeed, in very many passenger lifts the full automatic or push button lift is to be found. All electrically-driven lifts in this country have a worm and worm-wheel reduction between the motor and driving drum or sheave. Worm-wheels are now sometimes made with the rim and teeth of phosphor bronze affixed to a centre of cast-iron. The worm and worm shaft are invariably a solid forging of mild steel. The author then alluded to the double-screw system for lifts of heavy duty, by which thrust bearings are rendered unnecessary. A double worm—one right and one left-handed—on one shaft is cut from a solid steel forging, and these gear into two worm-wheels mounted above them, arranged tandem, and in mesh with each other.

For lifts doing heavy loads at slow speeds, such as those required for raising vehicles to upper floors, say of 1 ton capacity and over, the reduction is further increased by the use of spur gearing, in addition to the worm. The coupling flanges connecting the motor shaft to the worm shaft are especially large in diameter and wide in face to take the brake, which consists of cast-iron shoes, fitted with hard wood blocks, pulled up to the face by spiral steel springs. In some brakes a solenoid is so disposed that when excited by the supply current it exerts a force in opposition to the springs, thus releasing the brake.

The necessary operations which have to be provided for in the gear of all electric lifts are as follows :—For starting the lift : (1) the motor armature connections to be made for the required direction of the running; (2) the brake released, current applied to motor through starting resistance; (3) starting resistance gradually cut out; (4) accelerating winding (if any) cut out; (5) field weakened for speeding above normal (if required). For stopping the lift : (1) current cut-off motor, and brake applied; (2) starting resistance quickly cut in, with which operation the normal condition of the shunt field is restored and the acceleration coils (if any) are cut in again ready for a fresh start. Preceding the first of these operations in stopping, a slowing down device is introduced in some high-speed lifts before actual stopping takes place. The gear has also to provide for the following contingencies :—(1) It must not be possible to put current on the motor armature till all the starting resistance is in. (2) It must not be possible through any cause for the brake to remain off or the supply current to remain on the motor when the attendant has put over to the "off" or stopping position. (3) A mechanically-operated device, worked either by the drum motion or the cage, must be provided to automatically perform the attendant's duty in stopping the lift at the top and bottom floors should he fail to do so. (4) In passenger lifts or goods lifts in which an attendant may travel, there should be a further over-wind prevention device in the form of a knock-off switch cutting off the supply mains from the entire electric gear.

The author then took these conditions in order, considering in the first place the cage-switch system as applied to passenger lifts. The duty of the cage switch is simply to close pilot circuits exciting the up or down solenoids on the reversing switch. By this means only small wires are brought into the cage and small currents are dealt with. In systems in which the reversing switch is in the form of two separate switches independently operated by the respective solenoids, it is essential to provide an interlock so that both switches cannot act together. Where a single switch is employed for reversing, the solenoid plungers act upon the ends of a rocking-bar pulling the switch over one way or the other for the up or down direction. This arrangement, of course, requires no interlock. In lifts up to about 7½ h.p. a separate main switch is not necessary, the reversing switch being provided with suitable contact surfaces and quick break to take the arc. The reduction of arcing at main switch contacts is in some systems effected by splitting up the break into a number of parts. When this is done gun-metal or copper contacts, carrying 5 amps. per break on 400 volts, do not need magnetic blow-outs. On double-break switches carbon contacts are most suitable with magnetic blow-out on breaks exceeding 10 amps. at 400 volts. Copper in combination with carbon is suitable where the surfaces are of sufficient area. The starting rheostat is operated electrically in some systems, and by mechanical means in others. The electrically-operated starter has a simple solenoid action, in which the motion of the switch arm is regulated by means of a dashpot to the proper slow rate of movement required. The switch is generally drawn up to cut out resistance, and is given a quick fall to the bottom position by gravity. An objection to this form of rheostat is that the action takes place quite independently of the load on the motor. The lift may be much overloaded, but the solenoid starter takes no account of that and cuts out resistance at the same rate as under normal conditions. Consequently, before the armature has commenced to move it may be getting very nearly all the line voltage, and only the fuses remain for its protection.

The mechanically-operated rheostat is worked by the motion of the gear, so that resistance is not cut out until the motor begins to revolve. If the cage is so overloaded that the motor will not start, the armature current cannot exceed that definitely set to pass with the total resistance in circuit. The principle of gradually cutting out starting resistance is not so good as that of allowing an interval between each step for the motor to gain speed. The ideal condition for the motor is to wait on each resistance step until it has gained the speed and back E.M.F. corresponding to that step. In starters operated on this principle, the electromagnet is made of elongated shape, so as to present the pole face to a number of movable magnets which close the resistance units in succession. The magnets are at different distances from the pole face, and therefore are not all lifted together, but in succession, as and when the excitation of the magnet is augmented. This rises in proportion to the back electromotive force of the motor, thereby causing the units to be cut out at intervals depending on the rise of potential and speed of the motor. In another starter of this kind for lift work the resistance steps are operated by separate solenoids, which are set to come into action successively and automatically as the back E.M.F. of the motor rises. Three steps at most are required to bring the motor to normal speed instead of a number of contacts, as in the ordinary starter. In the event of an overload, the motor will not move on the first step, and succeeding steps will therefore not be cut out, thus protecting the armature from excessive currents.

In drum drives the means for prevention of overwinding is usually worked from the drum motion. This is usually a switch cutting-off current and releasing the brake in cage-switch systems. It is most important that nothing should delay the brake being immediately applied on the cessation of current. No passenger lift should be without two independent means for automatically arresting the motion of the cage in the event of its failing to stop at one or other of the terminal floors. In the drum system a slack-rope safety device is also necessary. The cage in descending may meet with some obstruction to check it. In that event, unless stopped, the motor would continue to wind up the balance weight and pay out slack rope on the cage side, a state of danger for the cage if it became released. The slack rope usually operates a weighted lever previously held out of action by the ropes when taut, which, thus freed, opens the safety switch, cuts off current, and applies the brake in the same way as is done by the limit switches. The slack rope device acts on both cage and balance weight ropes, so that in case the cage passed the first limit at the top floor, this stop would act when the balance weight touched the bottom. In a friction-drive lift the ultimate limit should be set to act before the cage or counterweight touches bottom. In this system of drive it is impossible to overwind should every automatic fail. If the cage should overrun the ultimate limit on the up journey, the balance weight will touch bottom, slacking the lifting rope slightly, so that it slips on the driving sheave. A similar action takes place if the cage touches the bottom buffers. The particular safety devices applicable to the drum drive are not applicable to the friction drive. But there are always three devices applicable, namely (1) the striking gear putting cage rope or cage switch to the off-position, (2) the knock-off tappet, and (3) the final safety action of slip in the driving sheave.

The author then drew particular attention to the amount of clearance or distance of overrun allowed between the top of cage suspension and the overhead gear when the cage is at the top, or between bottom of cage and bottom of well hole pit when the cage is in the lowest position. If possible there should be a clearance at top and bottom of not less distance than half the height of the cage. Coming now to the brake, it is most important that the excitation of the releasing solenoid should be instantly interrupted when the cage switch is put to the off position. If the excitation is derived from the main circuit, made alive by the main switch, the breaking of the latter will not interrupt it, as it will still be maintained by the voltage the motor continues to generate until stopped. Particular care is, therefore, necessary to see that the connections are made across the line, and suitably interrupted. The de-excitation of the brake magnet and the application of the brake should in no way be dependent upon the main switch or reversing switch coming off. The electrically-released brake is a very suitable one for electric lifts. If current fails or is intentionally shut down, the brake is applied. What would happen if the brake failed to be applied when the cage switch was put to the off position? The cage, either loaded descending or light ascending, will then continue its travel till the limit switch interrupts the main supply current. But under these conditions of out-of-balance load the motor is not being driven by the supply cur-

Digitized by Google

rent, but by the load or balance weight, as the case may be. It is probably generating a voltage equal to the supply or a little higher, and the current is extremely small, perhaps even supplied from motor to line. Consequently, the interruption of the main circuit will not arrest the cage. With the friction drive the rope would slip on the driving sheave upon the bottoming of cage or balance weight. There would be a slight impact on the buffer springs, but no danger, and absolute protection against running into the overhead gear. With the drum drive the ultimate protection would be the slack rope device coming into action after bottoming of the cage or balance weight. The bottoming of the cage would have the same final effect as in the friction drive, but the bottoming of the balance weight would have a somewhat different effect. The rope on that side would become slack, and the slack rope device would come into action, cutting off the main supply. The driving power would also cease upon the balance weight bottoming, but there would be some momentum in the cage and winding gear to be expended before the system came to rest, and if the clearance was small the possibility of fouling the top gear would have to be taken into consideration.

A slowing down device coming into action some little distance before the cage reaches the top or bottom floors is very useful to lessen the momentum of the cage when it is approaching the limits, especially in high-speed passenger lifts running at over 250 ft. per minute. The slowing down device used by one maker, which also gives the half speed on a two-speed lift, is brought into action by the ordinary use of the cage switch, and automatically by a pilot limit switch opened by a striker on the cage. It is effected by an extra field connected across the brushes. The limit device of the same maker on being operated disconnects a pilot circuit, thus opening the main switch and cutting off the supply of current, at the same time short-circuiting the armature through a resistance, bringing it promptly to rest, even though the ordinary brake be out of adjustment. Another maker employs a slowing down device by the re-insertion of the starting resistance and a dead resistance across the armature.

The shunt wound motor is most suitable for lift work on account of its approximately constant speed under varying loads. But when starting on load there is considerable weakening of the field owing to armature reaction with the heavy starting current. It is therefore a very great assistance to starting to have a series winding in addition to the shunt, which prevents the field strength falling in the first few seconds. The series winding should give about 15 per cent. extra excitation, and should be short-circuited automatically by the controller as soon as the starting resistance is all out. This prevents any check upon the proper normal speed of the motor. The shunt field should in every case be such as will give full excitation, the series excitation being additional to this. Series motors are not suitable for passenger lifts owing to the variation in speed with load, and the liability to reach an excessive speed on light loads. These motors are, however, very suitable for crane and hoisting work, where it is an advantage to be able to raise small loads at high speed, while heavy loads can be raised equally well at a slow speed. This advantage outweighs the loss of energy in regulation in the form of variable resistance in circuit with the motor. With regard to the rating of motors, the author had found that motors were quite satisfactory for busy lifts that will test at full load for one hour continuously with a maximum rise of 70° F., and stand an overload of 100 per cent. for one minute without flashing over or series sparking.

In the course of his paper, the author also referred to the uselessness of the no-voltage release for lift-work, and to the advisability of interlocking the gates so that the motor could not be started until all gates were closed, and further so that a gate could not be opened until the cage was level with the floor.

The Discussion was opened by the Chairman, Mr. E. G. Rivers (Chief Engineer of His Majesty's Office of Works), who thought, with the author, that in general there was far too little clearance allowed in both top and bottom positions between the cage and the fixed gear or girders. He also agreed with the author's recommendation of the insertion of a slowing-down device before the end of travel is reached. Mr. F. Broadbent said that owing to the low efficiency of the worm-gear, which was less than 50 per cent. if the gear was self-sustaining, there was a tendency to use spur-gearing with two brakes. Mr. Watkinson had noticed that in some of the slides of gears shown by the author, the worm was at the top; this would mean that the worm wheel makes half a revolution before any grease gets to the worm, whereas if the worm were below, it was greased almost at once. He thought it was a mistake to consider that a worm-gear was self-sustaining. A ball governor operating a brake was, in his opinion, a suitable safety device to use with lifts. Mr. J. T. Mould thought that the coils of brake magnets should be compound wound, as this admitted of a smaller shunt coil and more certain action. To prevent the cage from attaining an excessive speed in case of failure of supply, he thought a ball governor or an excess voltage relay should be used to actuate a brake. The method of inserting resistance in series with the armature to reduce the speed, would, in his opinion, be unsatisfactory, as, if the motor were generating, this would increase the speed. With regard to gate switches, if the main switch were a solenoid switch, this solenoid could be put in series with the gate switches, and then the solenoid would not operate until the gates were all closed.

To show the superiority of the electric lift as regards working cost, Mr. A. Day gave the following figures for the comparative working costs of two lifts under similar conditions of travel, load, &c. For the electric lift, the costs amounted to £3 18s. 6d. for one quarter, and for the hydraulic lift £18 10s. for the same quarter. Mr. Stevens thought that a properly designed worm gear should be self-sustaining, and that any form of non-self-sustaining gear was unsatisfactory. With regard to the wear of bearings, he thought that large surface cast-iron bearings well provided with oiling devices were better than small surface phosphor-bronze bearings. He was a strong advocate of the friction or Vee drive, as, directly the tension on the cables was released, the drive ceased. He thoroughly agreed with the author as to the uselessness of the no-voltage release in a great many cases. Mr. Wilkinson replied, and answered a few questions put by some of the speakers.

"Credenda" Conduits.—A recent visit to the works of the Credenda Conduits Co., of Scholefield Street, Birmingham, has convinced us of the fact that this newly-established branch of Tubes (Ltd.) has made an energetic start, and is in a position to supply all sizes of tubes and fittings for immediate delivery. Although the company supplies a well-finished conduit of both light and heavy gauge for socket joints, and a "continuity" nipple, the speciality of the Credenda Company is a solid-drawn weldless tube of the highest quality and finish for screwed work. The tube is made at the works of the parent company, Tubes (Ltd.), but the screwing and enamelling is carried out at the Credenda Co.'s works, where the fittings are also manufactured. Following the usual practice, the tubes are dipped in the enamel, which is kept at a suitable temperature, and after they have been allowed to drain off, they are stoved. The surface obtained is an excellent one; the finished tube appears as smooth and bright as a bicycle tube, and the enamel does not crack, even when the tube is sharply bent. The screw gauge of the Engineering Standards Committee is employed. All sizes of tube from ½ in. to 2 in. outside diameter are manufactured and stocked. For the couplings, elbows, and bends, the same solid-drawn tube is used; other fittings are made of malleable castings. A useful and well-got-up catalogue has been prepared, in which almost every conceivable fitting is included, and full dimensions are given. The company has now also taken up the manufacture of watertight fittings to Admiralty specification.

Private Telephone Lines.—The Master of the Rolls, Lord Justice Fletcher Moulton, and Lord Justice Buckley, sitting in the Appeal Court on Wednesday, had before them an appeal by the National Telephone Co. against a decision of Mr. Justice Swinfen Eady in the Chancery Division of the High Court, as to whether the company was bound to pay royalties in respect of private telephone lines. We reported the previous action in Electrical Engineering, Vol. I. p. 567. The point in dispute was as to whether private lines came within the exemptions of Section 4 of the Telegraph Act of 1869, where the line was used other than in connection with the business premises and private residence of a subscriber. Mr. Justice Swinfen Eady held that they did not, and that royalties must be paid on such lines. Sir Robert Finlay, K.C., Mr. Danckwerts, K.C., and Mr. H. H. Gaine were for the appellants, and the Attorney-General, the Solicitor-General, and Mr. Casserley appeared for the Crown. Sir Robert Finlay, for the company, contended that the provision stating "that no charge was to be made" showed that it was never contemplated that private wires should be confined to connecting different parts of the premises of the same occupier. He admitted, however, that if in the case of theatrical agents the apparatus were used for the purpose of putting hotel people in communication direct with the theatre that would not be covered by the exception. The Attorney-General, in supporting the judgment of Mr. Justice Swinfen Eady, contended that these private wires must be used strictly for the private business of the lessee. To bring the wire within the exception the dominant factor was that the line was to be for the private use of the lessee. The moment the line was used for the private use of two or more persons they got outside the exception. Lord Justice Buckley said he understood the learned counsel's argument to be that if he telephoned to his servant to send him a pair of boots it came within the exception, but if he telephoned to his bootmaker to make him a pair of boots that did not come within the exception. The Attorney-General replied that that was his contention. The Master of the Rolls inquired of Sir Robert Finlay what he would say if the Court held that the proper construction of the company's licence was such as to include private wires when used only by the subscriber between his works and residence, for instance. Sir Robert Finlay said the Crown had never taken this view before, and he would like to consider it. The case was then adjourned.

STEAM TURBINES

A PAPER was read on the subject of steam turbine engineering by Mr. S. L. Pearce, Chief Electrical Engineer to the Manchester Corporation, before the Manchester Association of Engineers, on March 7th. The preliminary part of the Paper dealt briefly with some of the elementary principles which form the basis of turbine design, and passed on to consider the work of early inventors and the development of the many types of the modern steam turbine. Descriptions of some of the leading examples of the different types were given, commencing with the De Laval and Riedler-Stumpf types as examples of the simple impulse turbine. The next type considered was the compound impulse type. In turbines which may be said to be compounded for pressure, the pressure drops by as many stages as there are revolving wheels, successive expansions of the steam taking place in the fixed diaphragms through which it passes from admission to exhaust. The two best known forms of this type, the Rateau and Zoelly turbines, were dealt with at some length, and an American design, the Hamilton-Holzwarth, was also referred to as falling within this class. In the type of impulse turbine compounded for velocity, the whole of the initial pressure of the steam is expanded and converted into kinetic energy in the first set of fixed guide vanes or nozzles. The high velocity, however, instead of being taken up by one single wheel, is exhausted in stages by passing through several alternatively moving and fixed vanes. The number of stages will again depend on the admission and exhaust pressure, and the best pre-determined velocity of steam for each stage; but in the case of the turbine "compounded for velocity," the total number will be remarkably small as compared with the previous type. The compounding of the Riedler-Stumpf turbine practically brings this turbine under this classification.

In the "Electra" turbine, a single impulse wheel is used as in the De Laval type, but relatively low speed is obtained by utilising successive impingements of the steam against the one wheel. The peripheral speed of the wheel is from 260 to 330 ft. per sec.

In the next type of turbine, which is compounded both for pressure and velocity, each stage consists of a set of expanding nozzles, and two, or more, rows of moving blades alternating with fixed blades. Between each stage is fixed a diaphragm with expanding nozzles. The total expansion of the steam therefore takes place in stages in the successive expanding nozzles, the kinetic energy developed at each expansion being absorbed as it passes through the successive moving and fixed blades of each stage.

The best known example of this class is the Curtis turbine, both in its vertical form as made in America and by the British Thomson-Houston Co. in this country, and in its modified horizontal form by the A. E. G. Co. in Germany.

The action of the Curtis is as follows:—Steam leaving the first set of expanding nozzles is directed against the first set of revolving blades, passing outwards through the row of fixed blades it impinges against the second row of revolving blades, finally emerging in the space at the end of the first *stage*. Entering the second set of expanding nozzles in the fixed diaphragm a further expansion of the steam takes place prior to the second stage cycle of operations, and so on to the end of the fourth or fifth stage.

In the second general class, the re-action turbine, there are practically no examples of a really pure reaction turbine, as most turbines commonly known as reaction machines are, in reality, combined impulse and reaction turbines. The chief example is, of course, the Parsons' turbine, in which stationary deflecting or guide vanes direct the steam against the blades of the running wheel. In the stationary vanes the whole of the energy of the steam is not converted into kinetic energy, so that on emerging from the guide vanes the energy of the steam is only partially kinetic. That part which is kinetic is utilised in imparting energy to the moving vanes as in an ordinary impulse turbine. The portion of the steam emerging from the stationary vanes which is not kinetic expands in the moving vanes, and by this process of expansion further helps to drive them forward. There is therefore a combined effort —partly impulse, partly reactive. Mr. Pearce referred to the various modifications which this turbine has undergone from time to time, and some of the troubles which were experienced with the early patterns. The differences in the designs of various makers who hold licenses under the Parsons' patents were indicated, including the retention of the double flow principle, discarded by Mr. Parsons in 1890 in the turbines of the Westinghouse Co.

In a comparison of the various types described, of which the De Laval, Zoelly, Curtis, and Parsons types may be taken as representative, it was pointed out that for electrical or any other work requiring large units, the former need not be considered seriously.

Taking, then, the latter three, it may be stated that as regards the first two an efficiency (made up of nozzles and vane efficiency) of 70 per cent. may be attained in practice, although 65 per cent. is more likely to be the actual figure, with a possible efficiency of some 80 per cent. The chief losses are condensation of steam, leakage from stage to stage, disc friction, eddy currents, and vane friction. The Curtis may have a slight advantage over the Zoelly in that whenever a leakage from stage to stage does take place, the losses are collected at the end of the main stages, and the steam may be usefully expanded in the following stages. On the other hand, leakage troubles with the Curtis may become as serious as they are with the Parsons type unless there is a steam-tight joint between the stages. With the Parsons type a possible efficiency of 83 per cent. may be reached, but in practice 65 per cent. is rarely exceeded, owing to the serious "leakage" factor. From the point of possible efficiency therefore the Parsons type stands well, but it is thought that in actual conditions there is not sufficient difference to warrant a decided opinion on the respective types.

As regards mechanical construction the balance of advantages may be said to be in favour of the impulse type. On the score of steam consumption the Parsons type has little to fear.

The chief drawback attached to the Parsons type of turbine is a mechanical one—viz., the risk or alleged risk of blade stripping. Blade stripping may result from four causes:—Inrush of water at starting up; distortion of the shaft, due to variable superheat, and consequent unequal expansion; variable vacuum, due to inefficiently designed condensing plant, and whipping of the rotor shaft, due to the extreme length. With properly arranged steam-piping and adequate trapping arrangements, inrush of water may be entirely avoided.

Apart from the economics of the question, it is not desirable to carry an excessive amount of superheat on the Parsons type of turbine. The author found on his visit to the Continent that almost every accident that had happened was traceable to the variableness of the superheat where excessive superheat was used. A moderate superheat of say not exceeding 125° F., should preferably be used with the Parsons type of turbine.

Variable vacuum should not occur with properly designed condensing plants. Unfortunately there have been some bad examples of this, resulting in variable vacua, and consequent excessive end thrusts on the shaft, causing fouling of the blades in an end-on direction. Whipping of the shaft is almost entirely unknown now, especially in the Willans type, for the reason that they have been able to shorten the rotor shaft.

The author then made a brief comparison between turbines and piston engines. He pointed out that the losses in the piston engine due to initial condensation and valve leakage were absent in the turbine, and that turbines had a decided advantage owing to their ability to expand the steam almost entirely down to condenser pressure. The turbine scores over the reciprocating engines also in that the frictional losses are reduced to a minimum by the absence of the many bearings

Regarding the losses incidental to turbines and not present in steam engines, the expansion of steam behind a piston is regular and smooth, while the expansion of the steam in a turbine used to give it kinetic energy with which to act on impulse blades is the reverse of a smooth and regular process. There is, therefore, a loss due to friction and eddies. There is, further, the loss incurred in the nozzles and guide vanes. Friction and eddies will produce heat, but at the same time they lower the efficiency of the turbine. The greater part of this heat may be given up to the steam, but the loss resulting from the friction and eddies remains, and constitutes the chief losses in the steam turbine.

The use of superheated steam improves both types of prime movers. In the case of a piston engine as a means of reducing initial condensation, in the case of the turbine as a means of reducing the fluid friction.

The following tables bring out the difference effected in such cases:—

Turbines.

Degrees of superheat, F.	13	50	70	100	150	200	260
Per cent. reduction of steam consumption...	6·1	8·0	9·5	14·0	19·0	23·0	24·5

Digitized by Google

Piston Engines.

Degrees of superheat, F.—	30	40	50	100	150	225
Per cent. reduction of steam consumption	7·8	8·65	12·0	20·5	13·0	33·1

Other points, some of them of a minor character, others important, which show in favour of the turbine as against the piston engine may be summarised as follows:—Less oil consumption, less staff required, less wear and tear, less housing space, floor space, and height, less cost of foundations, and less vibration.

The square feet of floor space per kw. for sets of 3,000 kw. capacity and over, may be put down at 0·35 square feet for piston engines, and 0·1 square feet for turbines. As a practical example, the author has been able to lay out the extension engine-room at Stuart Street for four times the capacity in turbine plant that would have been available for reciprocating plant; and by the utilisation of boiler units capable of evaporating 40,000 lb. per hour, the boiler-house lay-out can be made to keep pace with the engine-room.

Comparing the efficiency of the turbine with the piston engine from the thermo-dynamic point of view, it may be frankly stated that the latter will show to be the more efficient. The thermo-dynamic efficiency of the non-condensing engine is generally taken to be some 10 to 15 per cent. higher than the condensing engine, on account of the practicability of the more complete expansion of the steam in the former case. The difference is not present in the case of a non-condensing turbine. As a matter of fact, its efficiency is practically independent of the pressure range—at any rate in the Parsons type. From this it is inferred that, considered as a *heat engine* only, the turbine is inferior to the extent of some 15 per cent. From this, unbiased writers on the subject have inferred that were it not for the fact that the efficiency of a piston engine falls off as the back pressure increases, a practical disadvantage which results from its inability to expand down to very low pressure for the reasons previously given, the turbine would not have made the strides it has done. This is quite apart from the equally important question of initial outlay, which to the engineer responsible for large electrical undertakings has so vital an influence on the costs at which energy can be produced.

The author does not consider that any advantage can be shown for the steam turbine as against the piston engine for sizes of 500 kw. and under. On the other hand, given ample supplies of cooling water, for capacities above this figure, and especially for the larger units of 3,000 -5,000 kw., the turbine is pre-eminently the prime mover to be adopted for electrical work in our present state of engineering knowledge.

In the concluding portion of the Paper some notes were given on marine turbines, and appendices were added containing tables of particulars of the principal turbine installations from 3,000 kw. and upwards, and some historical notes on the development of the steam turbine. The following table on estimated comparative costs of running of turbine and reciprocating plant of 1,800 kw. capacity was given:—

	Turbine.	Reciprocating.
Capacity	1,800 kw.	1,800 kw.
Cost per B.O.T. unit—Oil	·0018	·006
,, ,, ,, ...Brushes	·0062	·00005
Repairs and maintenance per annum per set	£126	£162

Institution of Electrical Engineers.—The following is the result of the ballot for new members at the Institution on Thursday:—*Members:* T. Boyden, C. Koettgen, F. L. McKeever. *Associate Members:* W. W. Alston, E. J. Cox, J. H. Crossley, G. K Field, F. R. Marsh, S. W. Melsom, W. H. Perrow, T. H. Relton, C. R. Shaw, W. Winkworth. *Associates:* G. A. S. Atkinson, W. Frain, Captain A. Gardiner, R.E.

Electricity in Horticulture.—According to the *Western Electrician* (Chicago) a gardener named H. F. Hughart, of Minneapolis has been making some interesting tests on the effects of electric light on the growth of lettuce. Recently Mr. Hughart planted a bed of lettuce plants 2 in. high. At one end of the bed he placed an arc light, which was turned on each day at sunset, one-half the bed being shielded from the light by a curtain. A subsequent investigation was made, and it was found that in the dark bed the lettuce was 7½ in. high, while that under the electric light was 8¾ in. The heads under the influence of the electric light weighed 40 per cent. more than those grown with only the sun's rays for light. It is reported that classes in botany at the Minnesota State University are interested in the experiment, and tests will be made with other plants.

ELECTRIC SIGNS

THE Kevan Signs Co. have some attractive electric advertising signs on view in their showrooms in Charing Cross Road. The simplest of these consist of a concave metal reflector faced with a circular glass cover, on which is the advertisement. A single 16 c.p. lamp is sufficient even for a 24 in. diameter sign, and this may be provided with an automatic thermal "blinker," if necessary. The reflectors are made of thin hardened steel sheet, with a highly polished surface of nickel. The glass used for the cover has a granulated milky appearance, and has a rough surface inside, which has the effect of diffusing the light to such a degree that an equal illumination all over the sign is obtained. The high reflecting properties of the glass also cause the sign to show up well in the daytime. For instance, a letter or words cut out on a coloured metal sheet show up white in the daytime, but can be made to show up any colour at night by placing a coloured screen behind the white glass. Rectangular signs constructed in a similar way to the above, and containing from 3 to 12 lamps, according to the size of the sign, can also be obtained. One form of a rectangular sign for the interior of a window is left open underneath, so that the lamps inside can assist in the general lighting of the window. The speciality of the Kevan Company is their "Movable" sign, by which some beautiful colour effects are obtained. The body of this sign is well provided with reflectors, and the concave cover is of plain ground glass. The letter, word, or other advertisement, is cut out in metal, and suspended behind the glass cover. The single lamp in the interior is surrounded by a rotating cylinder, the wall of which consists of a mass of coloured transparent pieces of gelatine or similar material. Other devices, such as pieces of perforated metal, are also attached to the cylinder to obtain varied effects. The coloured light is partly projected direct on to the ground glass cover, and partly reflected from the mirrors in the body of the sign. By a very careful arrangement of the coloured transparent material and the other devices, a wonderful cloud-like moving effect, and a beautiful blending of colours is obtained, which cannot fail to attract attention. The cylinder is rotated either by means of a clock-work spring motor or an electric motor. Some signs of this description have recently been supplied by the Kevan Company to the Great Western Railway. In one of these the outline of a ship is silhouetted against a suitably coloured moving cloud-like background, and a very striking effect is obtained. Some of these larger signs are provided with 25 c.p. lamps, but only a single lamp is necessary, owing to the diffusing property of the glass used, and the careful arrangement of the reflectors.

X-Ray Dermatitis.—It is stated that Mr. T. J. Oliver, who for fifteen years has been in charge of the electrical department at the Leeds General Infirmary, has become a victim to X-Ray dermatitis, it having been found necessary to amputate one of his arms.

Hire of a Generating Set.—On Friday last, in the King's Bench Division, Mr. Justice Darling and a special jury had before them an action by Messrs. Williams & Sons against the Beckenham Urban District Council to recover a sum of £759, the balance of an account delivered for goods sold and delivered, and the hire of generating sets from October, 1906, to April, 1907, at £125 a month. Defendants had an option to purchase, but did not exercise that right. Defendants counter-claimed for £417, on the ground of insufficient output of the machinery. A verdict was entered for the plaintiffs for £500 and costs.

The British Association.—The Council of the British Association for the Advancement of Science has nominated Professor J. J. Thomson, F.R.S., Cavendish Professor of Experimental Physics in the University of Cambridge, to be president of the meeting of the Association which is to be held at Winnipeg next year. The investigations carried on by Professor Thomson in the Cavendish Laboratory, and by the distinguished men of science who first worked under him and received inspiration from his researches, laid the foundation for the new views held by chemists and physicists as to the electronic constitution of matter and the remarkable properties of radio-active substances. In 1894 Professor Thomson was awarded one of the royal medals of the Royal Society, and to this was added in 1902 the Hughes medal, in recognition of his contributions to the advancement of electrical science, especially in connection with the phenomena of electric discharge through rarefied gases. Two years ago he was the recipient of the Nobel Prize for Physics. It is understood that provision will be made by the Canadian Government in the estimates for the coming financial year, for a grant of twenty-five thousand dollars (£5,000) by the Dominion Parliament towards the expenses of the Association's visit to Winnipeg. The City of Winnipeg itself proposes to make a grant of five thousand dollars (£1,000). The week of the meeting will probably be from August 25th to September 1st, 1909.

EXTENSIONS OF GENERATING PLANT AT WOLVERHAMPTON

New Turbo-Generators for Power Supply

IT is only natural that the general appreciation of the advantages of electrical works driving and other applications of electrical power which have been so marked a feature of industrial progress during recent years should show themselves in such an important manufacturing town as Wolverhampton by a considerable increase in the power-load. That this has been so is evident from the extension of plant intended primarily for power supply, which were formally inaugurated on Monday evening at the Corporation Electricity Works. The complete scheme for dealing with the increased power demand involves the laying of a considerable length of special new power mains, as well as the provision of 2,000 kw. extra plant capacity in the station. The question of power supply has been dealt with quite separately from the existing lighting and tramway system, and although the whole of the older plant is continuous current, alternating-current distribution at 6,000 volts was decided upon for the new power scheme, and three-phase machines were for the first time introduced into the station.

Before describing the new plant in detail it is interesting to consider a few figures showing the growth of the power-load during the last five years. The following table gives details of the motors connected, and shows also how the load-factor has varied and the generating costs have steadily come down:—

Year ended March 31st.	B.H.P. of motors connected.	Load factor per cent.	Generating costs (not including distribution and management, &c.) in pence per unit.
1904	500	17·3	·811
1905	660	20·5	·561
1906	873	22·0	·506
1907	1,539	21·3	·477
Dec. 31, 1907	1,960	20·5	·471

The last line only gives the state of affairs at the end of 1907, so that by the time the three remaining months of the financial year are complete, the change will be even more marked. The power-load even now has overtaken the traction-load, as is shown by the fact that for the nine months in question the units sold for power numbered 1,298,040 as against 1,160,152 for traction.

An entirely new system of three-phase power mains is being laid. In the case of one of the largest prospective consumers, Messrs. Bayliss, Jones & Bayliss, a special pair of 6,000-volt three-phase feeders has already been laid, and a converter station of a capacity of about 1,000 kw. will be established at their works. A new power ring main will serve the works of Messrs. Thomas Parker, Ltd., and several other large power consumers. A sub-station containing rotary converters will be put down on Messrs. Parker's premises, which, in addition, to serving the works, will also supply a portion of the ordinary network in that district. Amongst other new 6,000-volt power mains will be one to the Chillington Tool Co.'s works.

It would be of interest, if space permitted, to trace the alterations in the system of supply which have taken place from time to time since the opening of the station in 1895 by the late Lord Kelvin. The method of distribution originally employed was what was at one time known as the "Oxford" system, with continuous-current generation at 2,000 volts and running machinery and batteries in the transforming sub-stations. This, however, gave place later to an ordinary three-wire system, with 440 to 460 volts between the outers, and at the present time only one of the original 140 kw. 2,000-volt machines is to be found in the station, and this is now used for arc lighting.

As will be seen from the plan in Fig. 1, the new generating plant, which consists of two Willans-E.C.C. 1,000 kw. turbo-alternators, with condensing plant and boilers, is housed in a prolongation of the east end of the boiler- and the engine-rooms, about 58 ft. in length. The actual extensions carried out only form part of the total projected scheme, the scope of which can be seen from the site plan in Fig. 2, where the positions of the six further turbo-generators and fourteen further boilers projected are shown dotted. The details of these future developments are, of course, more or less vague at present, but as far as has been decided, the units are to be of 2,000 kw. capacity each. In looking at this plan, one cannot help being struck by the fact that the area shown occupied by the turbine plant of a capacity of 14,000 kw. complete with boilers is little, if any, more than that of the original engine- and boiler-house containing plant of 3,230 kw. capacity driven by reciprocating engines. The new plant comprises, in addition to these turbo-generators, boilers, &c., and H.T. switchboard, a pair of converter sets placed at the other end of the old engine-room, which, as further explained hereafter, form the electrical connecting link between the new and the old plant.

A section of through the new part of the engine- and boiler-rooms, showing the relative positions of the new boilers, generating sets, condensing plant, exciting sets, and switchboard, is given in Fig. 3, and the appearance of the turbo-alternators themselves is shown in Fig 4. Each set has a full rated output of 1,000 kw. at 6,600 volts 50 cycles, with a power-factor of 0·85 when running at a speed of 1,500 r.p.m., and is also guaranteed to withstand an overload of 50 per cent. for two hours without bye-passing steam to the low-pressure section of the turbine. The guarantees of steam consumption, all of which, with the exception of some of the figures for overloads, have been realised in tests, were as follows—

Temperature of condensing water.	Steam consumption in lb. per kw. hour (saturated steam). Half-load.	Full load.	50 % overload.
71° F.	19·6	17·13	18·05
74° F.	19·8	17·3	18·2
80° F.	20·0	17·55	18·4
85° F.	20·6	18·07	18·8

The efficiencies guaranteed for the alternators are given below:—

Power factor.	Full load.	50 % overload.
1·00	89½ %	94 %
0·85	89 %	92¼ %

We understand from the manufacturers, however, that somewhat higher efficiencies have been shown on actual test, when the following figures were obtained on non-inductive load:—

Half-load.	Three-quarter load.	Full load.	50 % overload.
89·5 %	92 %	94 %	95 %

The turbines are of the standard Willans-Parsons type, the construction of which was described at some length in Electrical Engineering, Vol. I., p. 959, and are of similar design to the machines illustrated in the article in question, except for their smaller size and the fact that it has not been thought necessary to fit the electric gear to the governor for altering the speed from the switchboard. The governors are guaranteed to keep the speed constant within 1½ per cent. up to 50 per cent. overload.

The alternators, which were made by the Electric Construction Company, are of interest as representing

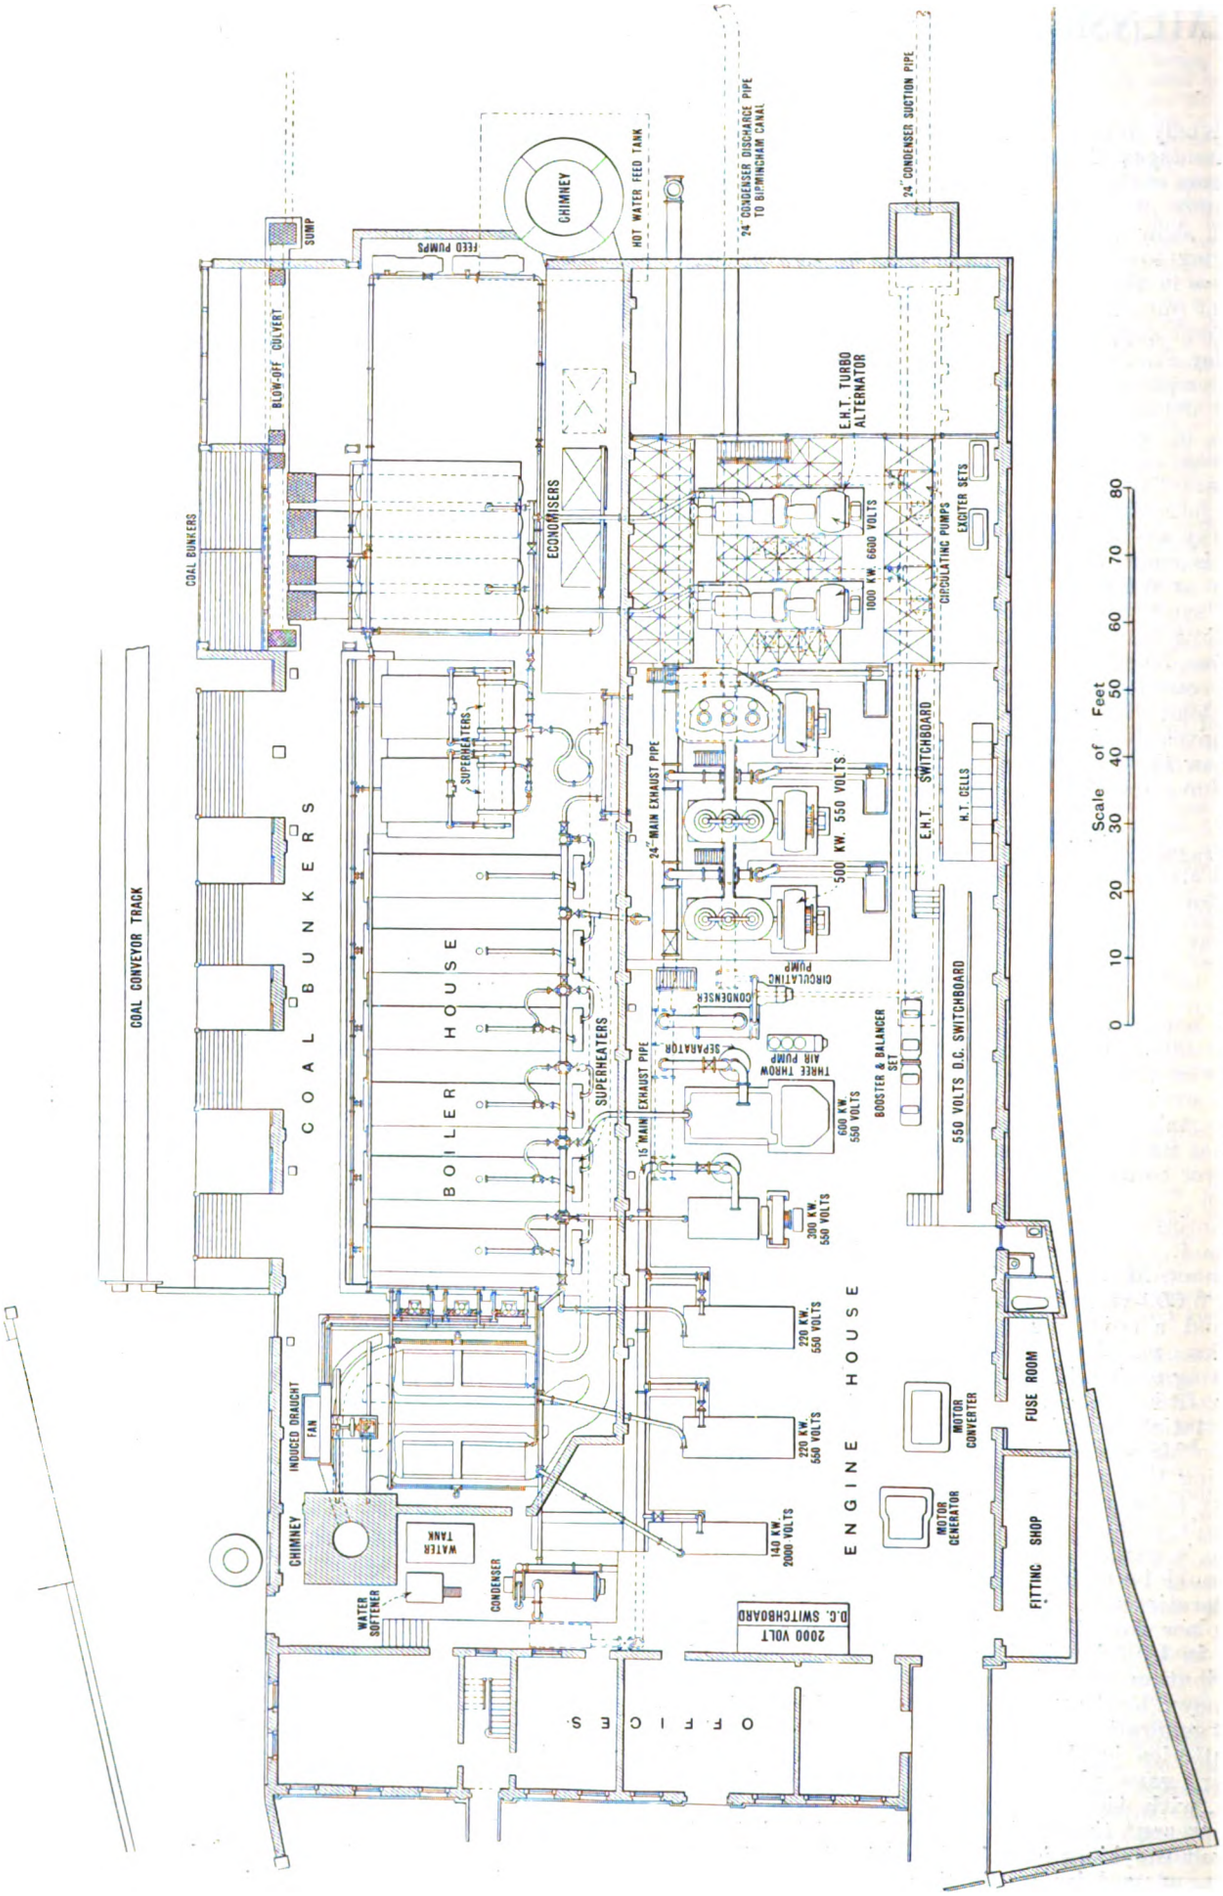

FIG. 1.—PLAN OF GENERATING STATION, SHOWING NEW EXTENSIONS.

Digitized by Google

a design which has not been seen before, as they are the first turbo-alternators to be delivered by this firm. The main point of difference from some other designs is the construction of the rotor, in which solidity of construction, simplicity, and smoothness of surface to avoid unnecessary windage resistance appear to have been the principal objects kept in view.

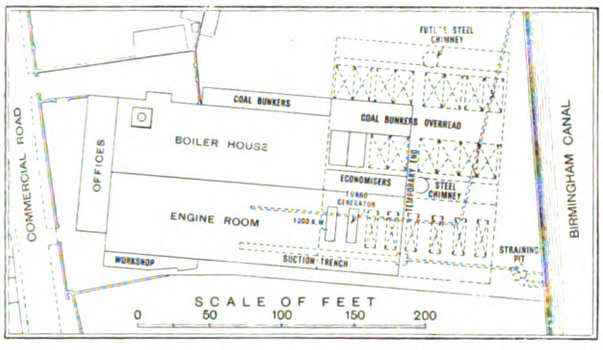

Fig. 2.—Sketch Plan Showing Proposed Future Extensions of Electricity Works.

The rotor is of the cylindrical smooth-core type, with distributed windings in open slots, and the actual core consists of a solid block of steel weighing about 4 tons. A special feature of the design is that the ordinary Continental practice of radial slots is not adopted, the slots being sunk in the direction shown in the sectional drawing given in Fig. 5. One of the advantages of this method is that the former wound coil can be placed directly in the parallel slots without disturbing the form of the coil. The winding in each slot is sub-divided into two or three sections, according to the depth of the slot, and each section is kept in position by phosphor-bronze wedges. The end connections of the field coils are secured by strong steel plates and phosphor-bronze keys, as shown in the drawing, and each element is thus supported individually. The field winding consists of flat strip wound on edge and compressed after having been placed in position.

This arrangement is not only particularly strong mechanically, but is capable of being very accurately balanced, and when once balanced there is little possibility of the distribution of weight altering.

The machine is protected by the strong cast-iron frame of the stator. This is provided with air suction and delivery openings, and cold air is drawn in at the base and ends of the machine and discharged from chimney-shaped openings at the top. This scheme of ventilation is very favourable to noiseless running.

The stator winding does not differ materially from other designs of turbo-alternator, but it should be said that the arrangement of the end connections is particularly neat, and at the same time great care has been taken to secure them rigidly in place, a question to which too little attention was paid in the early days of high-speed machinery. Each coil is held in position by two strong brass brackets, as shown in Fig. 5. Speaking generally, the machines strike us as compact for their output, and the attention that has been paid to their balancing is shown by their remarkably quiet running and freedom from vibration. It is evident that although they may be the first machines of their make to be run in a generating station, they are in no way to be classed as experimental.

The condensing plant was also supplied by Messrs. Willans & Robinson, and, as shown in Figs. 3 and 4, each set has its own condenser immediately beneath it. In contradistinction to the method sometimes adopted of coupling up the condenser rigidly to the exhaust flange of the turbine, and mounting the condenser body on springs to take up expansion and contraction, the condenser is mounted rigidly on its foundations, and an extensible "concertina" joint is placed between the turbine and condenser. This joint can just be distinguished in Fig. 4. The air pumps are of the three-throw Edwards type, gear-driven by continuous-current motors of the enclosed ventilated type, running off the 460-volt 'bus-bars. These motors were supplied by Messrs. Thomas Parker, Ltd

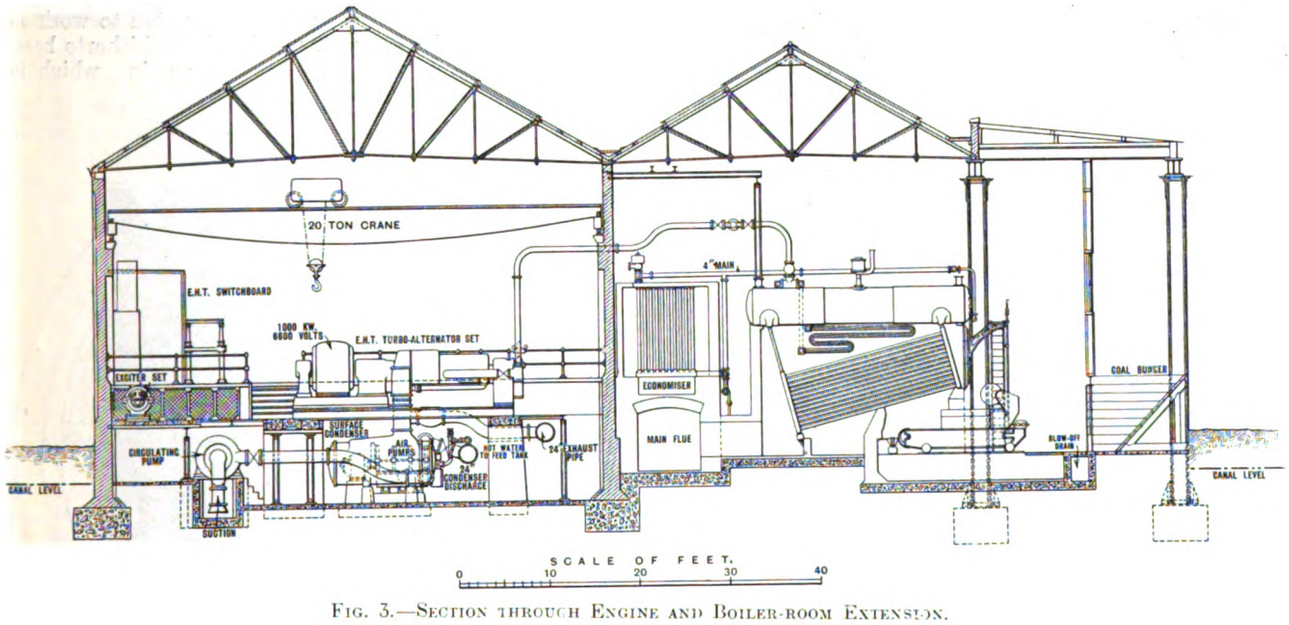

Fig. 3.—Section through Engine and Boiler-room Extension.

The position of the circulating pumps is shown in Fig. 3. They are of the Rees Roturbo type, of a capacity of 200,000 gallons per hour, supplied by Messrs. Thomas Parker, Ltd., and driven directly by their continuous-current motors. This form of pump, which is also in use in some of the other condensing plant in the station, is of rather different design from the ordinary pattern of centrifugal pump, and is calculated to obtain good efficiency over a much large range of volume and head when driven at a constant speed. It is claimed to be a true "turbine" pump, in that the rotor has a strong turbine effect due to the water passing through it. This effect is obtained by making the rotor of large

Digitized by Google

capacity for storing water, which is maintained by rotation at a practically constant internal pressure independent of the external head. By an application of the "Venturi" law this pressure is transformed and utilised with but little loss, and instead of throwing away the surplus speed energy of the water discharged, when the head of delivery is reduced, this energy is extracted from the water before it leaves the pump casing. Condensing water is obtained from the adjoining canal, so that cooling towers or ponds are not required.

A view of the new boilers is given in Fig. 6, and details of their arrangement are seen in Fig. 3. They are two in number, and are of Messrs. Babcock & Wilcox's standard water-tube type, with internal superheaters and without thermal storage vessels, and they are fitted with the last pattern of this firm's chain-grate stoker. The evaporative capacity of each boiler is 20,000 lb. of water per hour, and they are constructed to work at a pressure of 160 lb. per sq. in., but have hitherto been worked at a pressure of 135 lb. per sq. in., which is the pressure of the older boilers to which their steam range is interconnected in the manner shown in Fig. 1. It has thus been possible for these boilers, which have been erected for some months, to supply steam to the

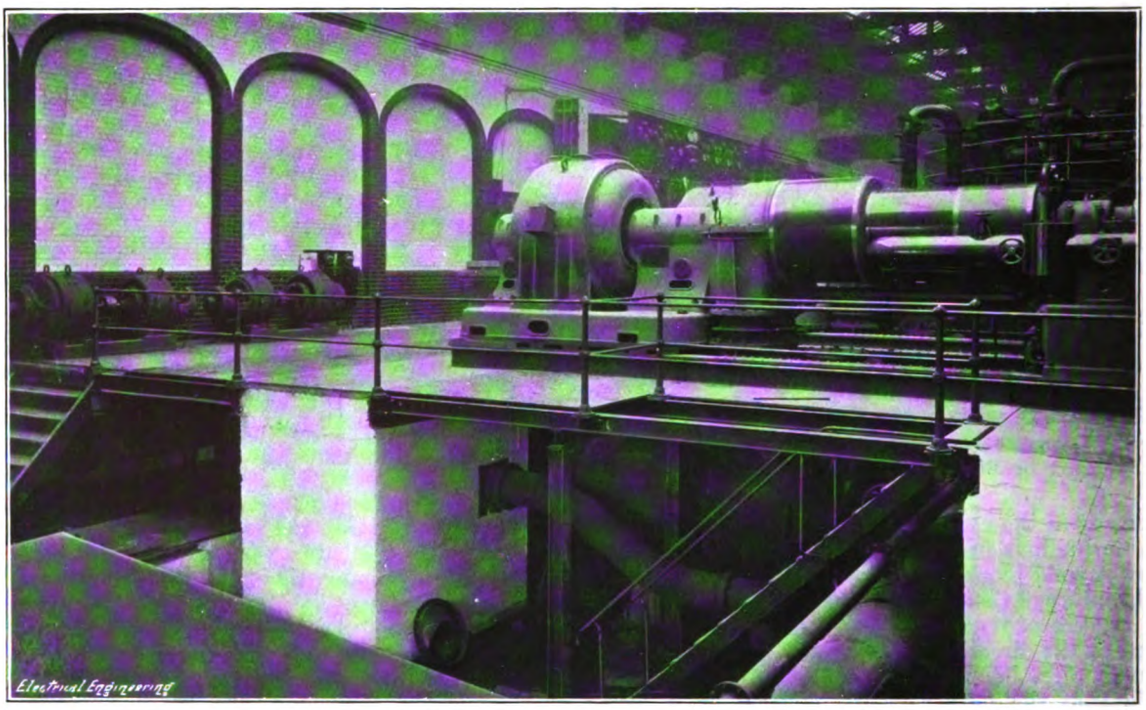

FIG. 4.—WILLANS-E.C.C. 1,000-KW. TURBO-ALTERNATORS AND MOTOR-DRIVEN EXCITERS.

older plant to assist in this last winter's load. The arrangement of the economisers, which were supplied

Fig. 6.—New Boilers.

by Messrs. E. Green & Son, in the flues behind the boiler is seen in Figs. 1 and 3. Although the present position of the coal-bunkers is opposite the boilers, provision has been made in the design of the boiler-house extensions for the addition of overhead bunkers at the time when the second row of boilers is added, and the steel-work which has been put in was designed to carry their weight. An entirely new chimney shaft has been constructed for these boilers. This is constructed of steel plate, and is entirely self-supporting without stays. The diameter at the base, where it is surrounded by a circular feed-water tank, is 15 ft., and the diameter at the top 8 ft. The height above the fire-grate level is 175 ft., and natural draught only is used. The contractor for the chimney and tank was Mr. J. Thomson, of Dudley. No new coal-conveying plant has been required. The boiler feed-pumps are electrically driven, and are of a special type developed by Messrs. J. Thomas Parker, Ltd.

The excitation of the alternators is supplied from a pair of motor generators, either of which is of sufficient capacity to supply both sets. These consist of standard four-pole motors running off the 460-volt continuous-current bars, driving similar generators each of an output of 375 amperes at 80 volts. As shown in Figs. 1, 3, and 4, they are placed along the wall opposite the turbo-generators.

Although primarily intended for power supply through the special three-phase feeders referred to already, arrangements have been made whereby the new plant can be employed to some extent for the ordinary lighting or traction load of the station by means of converting plant. These converting sets are shown in Fig. 7. The machine to the left is a 500 kw. "motor converter" of the La Cour type, supplied by Messrs. Bruce Peebles & Co., and the other machine is a synchronous motor-generator of the same capacity made by the Electric Construction Co. Both these machines run direct on the 6,600-volt three-phase circuit, and convert to 460 to 500 volts on the continuous-current side. This latter set runs at 600 r.p.m., and has an overload capacity of 25 per cent. for four hours, and 50 per cent. for one hour. Both sets have their starting gear arranged close to them, as shown in Fig. 7. The E.C.C. set is started up from the continuous-current side by means of a totally enclosed oil type starting switch. The starting switch has a slow motion arrangement of the ratchet type, by means of which each section of the resistance is cut out by one stroke of the hand lever. The switch is fitted with a no-voltage release, which will release the switch from any position during the starting-up operation or from the full-on position. In-

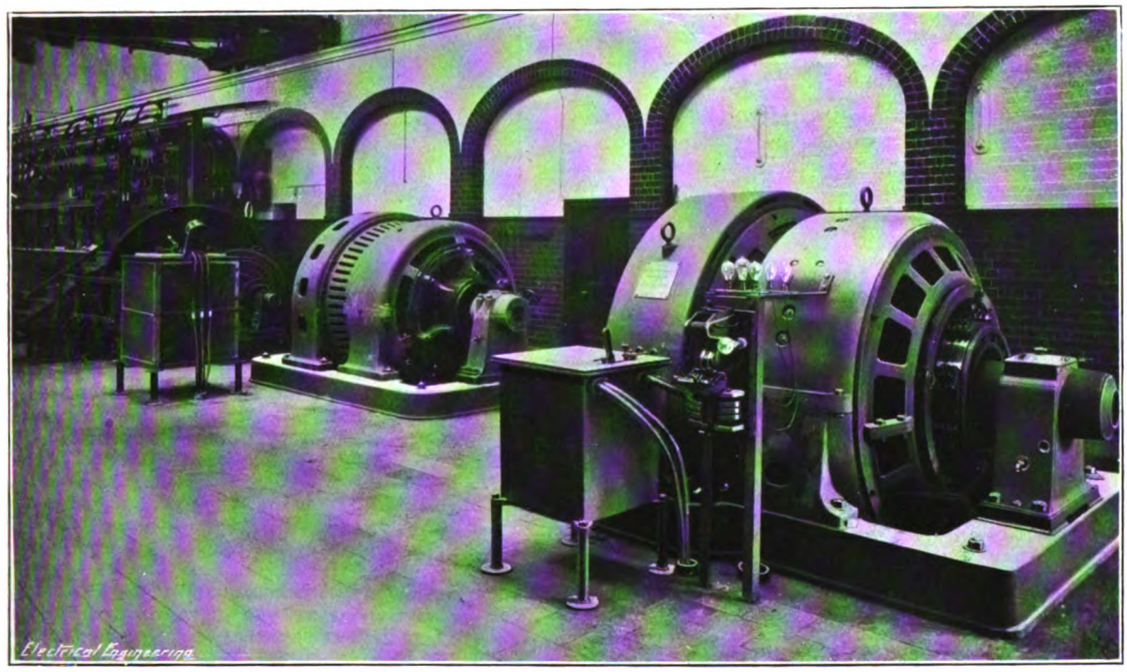

Fig. 7.—500-kw. Motor-converter and Synchronous Motor Generator Sets.

Digitized by Google

dicating lamps are provided on the starter, so that it can be seen from a distance whether the starting switch is on or off. Arrangements are made whereby the excitation of the synchronous set can be varied within considerable limits in order to be able to control to some extent the power factor of the system. This set is, of course, always started up from the continuous-current side. It will be noticed that both sets are arranged with the frames as close together as possible without any intermediate bearing.

The new high-tension switchboard which forms a part of the extensions, was also supplied by the Electric Construction Co. It is placed in a low gallery with a glass floor by the side of the continuous-current board. All high-tension apparatus is contained in cells separated by a passage-way behind the board itself. The actual board consists of eight slate panels, comprising two generator panels, a panel devoted to each of the converter sets, three power feeder panels, and a panel upon which are mounted the synchronising instruments, and also some of the switches and instruments belonging to the exciter circuits. All the instruments were supplied by Messrs. Everett, Edgcumbe & Co. The arrangement of the switchgear contains several points of interest, and we propose to give a fuller description of some of the details in our next issue. Although not at present installed, a Tirril regulator is shortly to be adopted for regulating the voltage, and we understand that a similar method of regulation is about to be applied to the continuous-current circuits for keeping the voltage at feeding-points constant.

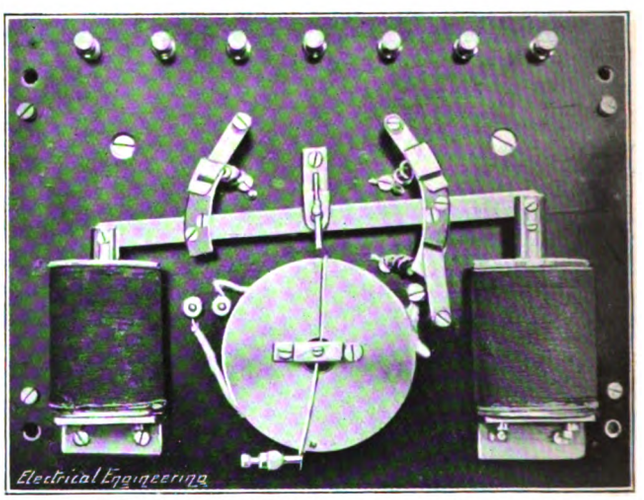
In relation to rapid increase of the power load at Wolverhampton, the following particulars of the prices charged for lighting and power are of interest:—

Lighting.—Private residences, churches, chapels, and charitable institutions, 4d. per unit; hotels and public houses, 2½d. per unit; theatres and music halls, 3d. per unit; shops, &c., 5d. per unit for first hour's use per day of maximum demand, and 2d. per unit for all consumed in excess thereof; special rate for lighting to power consumers, up to 10 per cent. of total power consumption for lighting at power rates.

Power.—Consumers of energy for power purposes using motors for 50 hours per week and upwards, 1d. per unit; consumers of energy for power purposes using motors less than 50 hours per week, maximum demand system. 2d. per unit for first two hours per day, ¾d. after; large consumers—300,000 units per year, ⅞d. per unit; larger consumptions, ⅞d. to ⅝d. per unit.

Before concluding, we wish to express our thanks to Mr. C. E. C. Shawfield, Electrical Engineer to the Corporation, who gave us facilities for inspecting the new plant, and kindly put at our disposal the drawings and photographs from which some of the accompanying illustrations were prepared, and also to Mr. H. A. Howie, his chief assistant. We are also indebted to the Electric Construction Co. for supplying us with drawings and technical details relating to the alternators and switchboard, and to Messrs. Thomas Parker, Ltd., for information relating to their portion of the contracts.

The following is a list of the principal contractors and sub-contractors for the different parts of the work, together with the amounts of their respective contracts:—



Steam turbo-alternators and condensing plant, Messrs. Willans & Robinson, Rugby, £12,514; Sub-contractors, alternators, The Electric Construction Co., Wolverhampton; Sub-contractors, circulating pumps, Messrs. T. Parker, Wolverhampton; switchboard, The Electric Construction Co., Ltd., £987; cables, Callenders Cable and Construction Co., Ltd., London, £4,000; boilers, economisers, and feed pumps, Messrs. Babcock & Wilcox, London; £5,197; sub-contractors, economiser, Messrs. E. Green & Sons, Wakefield; sub-contractors, feed pumps, Messrs. T. Parker, Ltd., Wolverhampton; buildings and foundations, Messrs. H. Gough & Sons, £4,550; steel chimney and feed-water tank, Mr. John Thompson, Dudley, £833; valves, Messrs. J. Hopkinson, Huddersfield, £220; steam pipes, Messrs. Foster Bros., Wednesbury, £200; feed-water pipes, Messrs. John Spencer, Ltd., £70; floor plates, Messrs. T. Bridges & Sons, Wolverhampton, £157; exciters, Messrs. T. Parker, Ltd., Wolverhampton, £416; motor converter, Messrs. Bruce Peebles, Edinburgh, £1,405; motor generator, The Electric Construction Co., £1,484; switchboard platform, The St. Pancras Ironwork Co., London, £130; voltage regulators, The British Thomson-Houston Co., Rugby, £420.

The inauguration of the plant took place on Monday evening, when a large number of persons were present at the Electricity Works at the invitation of the Corporation. The proceedings commenced with a reception by Mr. Gough Allen, chairman of the Electricity Committee, and after a few speeches handsome souvenir keys were presented by Mr. Shawfield to the Mayor, Mr. F. Evans, and to Mr. Allen, by means of which the formal ceremony of putting the new plant to work was accomplished by unfastening the large padlocks which had been affixed to the steam valves, &c. The company then reassembled in the offices, where supper was provided, and a number of toasts were honoured. Councillor Gough Allen presided, and spoke of the great extensions in the use of electrical driving and their effect on mitigating the smoke nuisance. Mr. Shawfield referred at some length to the boom in power supply which had led to his recommending these extensions, and emphasised the importance of supplying power at a low price. Mr. Shawfield finally proposed the contractors, and Mr. E. J. Fox (Messrs. Willans & Robinson) responded.

AN AUTOMATIC TRANSFORMER SWITCH

IN connection with the extending use of the types of small transformers described in Electrical Engineering, March 6th, p. 351, the following particulars of an automatic switch, which has been patented by Mr. P. Good, will be of interest. The switch is manufactured by Messrs. Knapton, Bagnall & Co., of Charlton, and its appearance, with the cover removed, can be seen in the accompanying illustration.

The shunt coil shown on the left-hand side is connected across from the supply mains to the low-pressure mains, through the

Automatic Switch for Cutting-out Small Transformers to Avoid No-load Losses.

switch shown on the left-hand side. As soon as a lamp is switched on anywhere in the house, it allows current to pass through this coil, which, attracting its core switches on the transformer, and at the same time cuts itself out of circuit. During the time current is passing in the house mains the needle on the main coil is deflected; as soon as the last light is switched off this needle comes into contact with the screw which connects the second shunt coil across the mains, this in its turn attracting its core switches off the transformer, and cuts itself out of circuit.

We understand that in addition to the separate form of switch with a sheet-iron cover, the switches are sometimes arranged in the same cast-iron cases as the transformers.

Presentation of a Portrait of Ampère to the Institution of Electrical Engineers.—At the meeting of the Institution of Electrical Engineers on Thursday last, the President announced that the Société Internationale des Electriciens had notified the Institution through their President that they are presenting the Institution with a portrait of Ampère, in commemoration of the visit of the French Society to this country in 1906.

"AMERICA REVISITED"

Lecture by Sir William H. Preece

SIR WILLIAM H. PREECE, K.C.B., F.R.S., delivered a lecture on "America Revisited, 1907," at the Institution of Electrical Engineers last Thursday. He has visited the United States four times—in 1877, 1884, 1893, and 1907. His first visit was made in company with the late Sir Henry Fischer to investigate the telegraphic system on behalf of the British Post Office. He reported on the success of the telegraph sounder in the States, and the result was the great development of its use in this country. On his return from this visit, Sir William Preece also brought back with him the first Bell telephone to make its appearance in Europe. During his last visit in 1907, Sir William was the guest of Mr. Andrew Carnegie on the occasion of his dedication of the Carnegie Institute to the city of Pittsburg.

The lecturer stated that one of his first impressions when he reached the country was the extended use of the telephone in the hotel at which he was staying, where arrangements existed enabling any visitor to use the telephone in his bedroom to communicate on the trunk lines; there were 813 telephones in the hotel. Another application of electric power was the driving of the vacuum cleaning apparatus, which is laid on by means of permanent pipes to every room in the building, so that by means of a flexible hose this process can be used for cleaning the room. He remarked on the large number of isolated generating plants in New York, exhausting steam into the atmosphere from the tops of the lofty buildings, in spite of the fact that the whole of the public electricity supply in New York is in the hands of one enterprising company, who do the work as well as it can be done. The lecturer then referred to the large building presented by Mr. Carnegie as a home for the engineering societies, the Engineering Club, and the McGraw building. The first of these accommodates the Institutes of Electrical Engineers, Mechanical Engineers, and Mining Engineers, and welcomes other engineering institutions as its tenants. It is a thirteen-storey building, and a floor is allotted to each institution. In addition, there is a large auditorium seating 1,000 people, and two smaller meeting rooms. Sir William spoke enthusiastically of the comfort and convenience of the thirteen-storey Engineers' Club, and the eleven-storey McGraw building, in which the *Electrical World*, *Street Railway Journal*, *Engineering Record*, and *Chemical and Metallurgical Industries* are published.

A large number of lantern slides were shown illustrating these buildings and other points of interest, and also a few of the technical schools of the Carnegie Institute in Pittsburg. The lecturer said there was a remarkable difference between the United Kingdom and the United States in their attitude to education. Here we expect the Government to do everything, whilst there they expect the millionaire to do it. In the United States there is no supreme Board of Education or Minister of Education. Every State had its own system, and the work of university training and technical education was the result of private munificence. Pittsburg, for instance, had already received $4,000,000 from Mr. Andrew Carnegie, who had placed the management of the institution in a splendid board of trustees, who were all Pittsburgers. The Institute covers four acres, and another 32 acres given by the city have been allotted for the technical schools. The present buildings have only been adapted for first-year students, but as the course will be four years, additional buildings are being erected, and there will be accommodation for 1,500 students. The present buildings provide for about 4,000. In connection with the opening ceremony, Sir William delivered an address on "The Connection between Science and Engineering," and he received the degree of LL.D. from the Western University of Pennsylvania. The lecturer added that he would be dealing with the question of technical education in America, in a Paper shortly to be read before the Society of Arts.

The output of Pittsburg in electrical and allied manufactures in 1906 aggregated $131,100.000, divided as follows:—Electrical and Auxiliary Manufactures, $45.000.000: Air Brakes, $10.000.000; Underground Cable and Wire, $71.000,000; Railway Switches and Signals, $5.100.000. The greater portion of this was turned out by the Westinghouse Company.

The following statistics relating to telegraphy show the progress made at the time of each of Sir William Preece's visits:—

	1877.	1884.	1893.	1907.
Mileage of wire ...	300.000	433,726	769,201	1,321,199
Offices open	11,660	13.600	21,078	24,760
Messages ..	28,500,000	40,000,000	66,591,856	148,804,000
Capital ...	$60,500,000	$80,000,000	$123,000,000	$140,000,000
Income ...	—	—	$24,978,440	$32,856,406

The result of his 1877 visit has already been mentioned. In 1884, he said, the only novelty was the Delany's Multiplex, which was subsequently introduced into the British Postal system. In 1893, the chief improvement noticeable was the large introduction of underground lines, in which, however, Great Britain had been considerably in advance, for in this country underground wires were started in 1837. America, on the other hand, had to be forced by fierce legislature enactments to place their wires underground. An advantage which the United States had over this country was that they had what might be called a better message load factor in the telegraphic service owing to the difference in time of three hours between New York and San Francisco, so that the period of maximum traffic during the day is extended. In 1907, the Wheatstone automatic working had been greatly improved by Mr. Barclay, the Assistant General Manager of the Western Union Telegraph Co. A typewriting machine was employed for punching the tape, but the receiving instrument recorded in bold Roman type at the rate of 100 words per minute. Whilst Sir William was in New York, one circuit in Poston cleared off 1,097 messages in nine hours. The system has been adopted by the Western Union Co., in preference to the Buckingham or Murray systems, and the following circuits were at work from New York: Chicago, six; Boston, two; Philadelphia, two; Buffalo, one; St. Louis, one; Pittsburg and Atlanta were about to be added. As the operator need not know the Morse code, a typist can work the machine, and this added very materially to defeat the recent strike of the Western Union operators last year, as a number of female operators were available to carry on the work after a very short training. The system, he added, is very accurate; on a Chicago circuit 800 messages were sent with only two repetitions.

Recently the telegraph companies revised their tariffs, and this resulted in an average increase of 2 per cent. in rates. There was no outcry against this as there would have been in England if the Post Office had ventured to raise the rate—in spite of the fact, said Sir William, that in Great Britain the Press, with its ruinous rate of 2d. per 100 words cost at one time £600,000 per annum, and the railway companies have a free service over the whole Post Office system. The income for the year ended March 31st, 1907, on the Post Office telegraph system in this country was £4,369.227.

Turning to telephony, the lecturer gave the following statistics of the growth of the Bell system in the United States:—

	1884.	1893.	1907.
Miles of wire	115.255	440,793	7,468,905
Telephones	162,787	552,720	3,553,418
Subscribers	123,625	232,140	2,741,367
Exchanges...	1,325	1,351	4,889

He also made comparisons as follows between the telephones in use in New York, Chicago, and Philadelphia, and some of the principal European cities:—

	Population.	Telephones.	Telephones per 100 population.
London ...	6,580,616	130,101	1·98
New York ...	3,437,202	279,047	8·12
Paris	2,660,559	62,370	2·34
Berlin	1,888,848	83,824	4·43
Chicago ...	1,698,575	126,436	7·44
Vienna	1,674,957	27,541	1·64
Philadelphia..	1,293,697	95,914	7·41

It appears that in America the maximum size of the multiple sections is 10,000 jacks, and that the same process is about to be followed as here—namely, to erect larger exchanges in which the ordinary subscribers' multiples are dispensed with, so that all calls are treated as junction calls. This system, introduced by Mr. J. J. Carty in New York under the name of the Partial Multiple Board, was introduced in London by Sir John Gavey, and is in use at the London Central Telephone Exchange. The lecturer said it was gratifying to find that the automatic visual signal has become universal, and he himself claimed that he was the original user of it in the Newcastle Exchange of the Post Office in 1880. He admitted, however, that its use on the central battery system with glow lamps was different to his original system of needles, but contended that the principle was the same in both cases. Incidentally, Sir William referred to the large increase in power required for telephone switchboards, stating that a 10,000 multiple board on the C.B. system required 500 amperes on the average, and 2,000 amperes on emergencies. He did not have an opportunity to inspect the automatic switchboards, but does not believe in them except

Digitized by Google

for small private branch or local exchanges, as they make the fallacious assumption that the lines are always in working order, and the called subscriber always at his post; actually, he said, they cost more to work than manual boards, as they require highly-paid technical attention. Sir William spoke much in favour of the toll rate of charging in place of the flat rate. In America it appears that the number of conversations per day per circuit is six. He referred to the large increase in the number of lines per route. Lead-covered paper cables are made carrying 600 circuits. Even pole lines carry 600 pairs of lines instead of 40, by the employment of aërial cables. Loaded lines on the Pupin method much increased the capacity of underground work, and there is a good working system of circuits from New York to Philadelphia, which are nearly 100 miles apart. A convenient use of portable telephones in restaurants was mentioned by Sir William Preece, the arrangements being that the guest can have a telephone at his table connected from a wall socket just the same as a portable lamp. In this way, he said, "You can eat, drink, and converse at the same time with your wife at home or your partner at the office."

The next section of the lecture referred to the "telharmonium," invented by Dr. Thaddeus Cahill. The keyboard is like that of a piano or organ, but each key is a simple switch which completes an electrical circuit, and operates a relay. The action of the relay is to lift a balanced strip of wood along which are fixed contact pieces, closing the circuit of one or more of the 144 inductor alternators which form part of the machine. Each of the alternators consists of rotating toothed wheels driven by a 185-h.p. continuous-current motor. The waves of current corresponding to the various notes and superposed harmonics, which can be modulated over a large range by means of stops so as to reproduce more or less accurately, the music from various instruments, are transmitted by underground cables to large Bell receivers.

The lecturer then gave tables referring to the position of electric lighting in greater New York in 1907, which he compared with statistics for London. The city of New York is made up of five boroughs :—

	Population in 1900.	Area in square miles.
Manhattan	1,850,093	22
Bronx	200,507	39
Brooklyn	1,266,582	66
Queen's	153,000	124
Richmond	67,021	37

The Edison Co. supplies on a three-wire continuous-current system at 2×120 volts. It has four generating stations :—Duane Street; East 12th Street; West 26th Street; and 140th Street, Bronx; in addition to the large modern station at Waterside, in which current is generated at 6,600 volts three-phase, and transformed to 2×120 volts continuous current at 15 sub-stations. This Waterside station has now been duplicated, and the two stations combined will have a capacity of 150,000 kw. 8,000 kw. is the size of unit adopted for the latest turbo-generators. While Sir William was in New York, a 5,000-kw. and 4,000-kw. reciprocating set failed at the same time in two stations working in parallel, but the only result was a perceptible diminution of pressure for some minutes in the upper part of the town.

The diagram below shows the loads on a summer and winter day. There is, the lecturer added, another allied company supplying two-phase current, 60 cycles, and 7,500 volts, which is stepped down in motor-generator sub-stations. It has occasionally helped the Edison Co.'s Waterside station over sudden high peaks. An instance of this is shown in the maximum curve, December 14th, 1906, in which the Waterside station supplied up to 86,400 kw., the four low-tension steam stations took the peak up to 102,400 kw., 7,500-volt supply from the United Electric Light & Power Co., supplied power necessary to increase the output to 112,000 kw., and the batteries made the top of the peak. Curtis turbines are largely used, and Sir William quoted some tests of a 8,000-kw. machine in Fisk Street station, Chicago, which gave 14,132 kw., with a steam consumption of 13·13 lb. per kw. hour, the steam pressure being 194 lb. per square inch, superheat 150° F., and the vacuum 29·31 in. This was on a 24-hours' test, made by Messrs. Sargent & Lundy, consulting engineers, of Chicago. The tariff charged by the American companies includes free replacement of lamps. Reference was also made to the electrical testing laboratory under the direction of Dr. Clayton Sharp, in which, in the year ending April 30th, 1905, thirteen million lamps were tested.

Incidentally, Sir William Preece referred to the fact that the Engineering Standards Committee is about to take up an investigation of the efficiency of the new metallic-filament lamps with a view to framing a specification and getting out standards. We trust that Sir William is not quite correctly informed in this instance, for it is far too early to standardise the metallic-filament lamps.

There are now three great railway systems worked electrically

Load Diagram.

The New York Edison Co. Waterside Station.

in New York, which have merged into one system, called the Interborough Rapid Transit Co. These railways are the Metropolitan Street Railways, the Elevated Railways, and the Subways. The New York Central and Hudson River Railroad has also equipped some of its suburban and main lines electrically. The Metropolitan Street Railways means the surface tramway system of New York and Bronx. It includes about 500 track miles. Although its earnings are considerable, Sir William said that its finances have been strangely "ping-ponged," and disastrous panic has followed since his visit. The service in Manhattan is on the metallic circuit conduit type, which has been so satisfactorily followed by the London County Council, and the northern section is overhead trolley, much of which is single track. There are over 200 miles of conduit track. The pavement is either asphalt, granite sets, or wood blocks, and the last seems the most favoured, in spite of its expense. Two generating stations in Manhattan transmit alternating current at 11,000 volts, three-phase, and 25 cycles, to a sub-station, where it is transformed down to the line pressure. The units are 3,500 kw., with reciprocating engines, and the load factor, it was said, varies from 60 to 65 per cent.

The Elevated railways frequently carry one million passengers per day, and the motive power was completely changed from steam to electricity in 1903. This increased the carrying capacity by 33 per cent., and the working costs were reduced from 55 per cent. to 45 per cent. of the gross receipts. They are

Digitized by Google

supplied by a generating station equipped with three-phase alternators, driven by reciprocating engines. The pressure in this case is also 11,000 volts and 25 cycles per second, and the line current is supplied from sub-stations at 625 volts. The third-rail system is used with track return. The units in the station are 5,000 kw., and the net output reaches 700,000 kw.-hours per day. Each six-car train consists of four motor-cars and two trailers, and each motor-car has two 125-h.p. motors.

The Subway has four lines, which extend from one end of Manhattan to the other; two of the lines are for local stopping traffic, and two for express service. There are 48 stations, 23·57 miles of subway and elevated structure, and 72·61 miles of single track. The construction of the Subway has been described in a Paper recently read before the Institution of Civil Engineers, an abstract of which appeared in our last issue. The power-house is on the Hudson River, and its capacity is 100,000 h.p. There are six sections, each complete in itself, with its own chimney, and each served by 12 boilers, and all the boilers are on the floor level. The plant includes eleven 5,000-kw. reciprocating sets, generating at 11,000 volts, 25 cycles, and four 1,250-kw. turbo-alternators, at 60 cycles, for lighting. The conversion to continuous current at 625 volts is performed in eight sub-stations with rotary converters. The third-rail system with track return is employed. The local stopping trains are made up of five cars, three being motors, the express trains are made up of eight cars, five being motors, and three trailers. The latter run at a 2½-minute headway. The motor-cars have two 200-h.p. motors on one truck. The electro-pneumatic block interlocking automatic signal system is used on the Subway, similar to that which has been introduced in the underground railways in London

The New York Central and Hudson River railroad is being equipped for electric traction as far as South Croton (a distance of 34 miles), on the Hudson section of the line, and to White Plains (a distance of 24 miles), on the Harlem section. There will be four tracks throughout, so as to separate the suburban from the through traffic. Current is generated at 11,000 volts 25 cycle three-phase, and is distributed to eight sub-stations, where it is transformed with transformer and rotary converters to a current of 660 volts continuous for the third-rail system. An under-running system is employed for collecting current, and the return is by the track rails. There are two power-houses, one at New York and one at Port Morris, which are identical in design, and each of which will have a capacity of 30,000 kw., with room for considerable extensions. The capacity of the coal bunker in each case is 3,500 tons, and Roney mechanical stokers are used. The generating sets are 5,000 kw. Curtis turbines, and the exciters are independent turbo-generators of 150 kw. capacity, supplying continuous current at 125 volts, and having a battery of 74 cells for 1,200-amperes capacity as a regulator and standby. The switchgear is contained in a separate building from the engines and boilers, at a distance of 40 ft. from the main building, in order to secure absolute safety from fire. The battery also is placed in this building. The locomotives weigh 95 tons, and carry four series-wound motors, one on each driving axle, giving a maximum of 3,000 h.p. The armatures are mounted directly on the axles, and the field magnets are attached to the locomotive frame. The locomotives are designed to accelerate at 1·5 ft. per second, and to drive a train, weighing 500 tons, 60 miles an hour. Sprague's multiple system is employed for the suburban service, and the motor-cars have two motors of 200 h.p. each, and one bogie. Tests made by the railway company at Schenectady on an experimental line of six miles, showed that the time required to reach the speed of 50 miles an hour in the case of steam locomotive was 203 seconds, and in the case of electric locomotive 127 seconds.

Only nine lines in the lecture were devoted to wireless telegraphy. "As a business," Sir William Preece says, "it is frosted out." Considerable trouble apparently arises from the American Morse alphabet being slightly different from the European code.

Bequest to Dundee College.—In memory of the late Lord Dean Guild, Mr. T. L. Peters, his sister, Mrs. Garden, and Miss Mary Peters have bequeathed a sum of £4,000 to University College, Dundee, for the erection and equipment of an electrical engineering laboratory. The conditions of the gift are:—(1) That the laboratory shall be regarded and accepted as a gift to University College, Dundee, and that it shall be vested in the trustees designated in the deed of gift of endowment and trust of University College; (2) that the College shall provide an adequate site for it, and shall maintain the laboratory in a state of efficiency, and shall carry out in it the purposes for which it is intended, as defined above; (3) that the building shall be a separate structure apart from the other buildings of the College, and that the name of our late brother shall be permanently associated with it.

ELECTROCHEMISTRY AND ELECTRO-METALLURGY

IN the *Chemiker Zeitung* of March 11th there is a note comparing aluminium with copper for conveying electric currents (cf. ELECTRICAL ENGINEER, February 13th, p. 244). It is remarked that in a good many cases in Canada and the United States, aluminium is employed for carrying the current in place of copper. For example, the Canadian Niagara Power Co. use aluminium leads to convey electricity to Buffalo. This fact is, of course, of particular interest, seeing that the United States is the land where the bulk of the copper is electrolytically refined, and therefore the metal so produced has a higher conducting power than less highly refined copper.

Now whether aluminium is cheaper to employ than copper depends upon the ratio between the price of the one and the other. When the ratio of the price of copper to the price of aluminium is greater than 0·54, then the employment of aluminium has an advantage over that of copper. Recently the price of aluminium has dropped by 33⅓ per cent., being at present about 2s. per kilo., while the price of copper is about 1s. 3½d. per kilo. At these prices aluminium has an advantage over copper. That is to say, weight for weight and price for price, aluminium has a greater conducting capacity than copper. One of the chief disadvantages in the employment of aluminium was the difficulty experienced in soldering and welding, it being necessary to join the sections by means of clamps. This appears now to have been overcome by the process of M. U. Schoop (ELECTRICAL ENGINEERING, Vol. II., p. 598). By means of this method an ordinary soldering lamp can be used to join wires of ⅛ inch diameter, and by means of an oxy-gas flame quite thick sheets can be welded. The flux used, it will be remembered, is an alkali metal chloride solution, *e.g.*, potassium chloride. It is only necessary to brush this solution on the parts to be joined, bring them together, and then to play the flame upon the part. Or for heavier work the flux is dusted upon the surfaces, which are then heated. The present price of aluminium and the new welding process now point to the possibility of aluminium entering into severe competition with copper, and gradually ousting it for conducting purposes. According to *Electrochemical and Electrometallurgical Industry*, of March, a company has been formed in Zurich with a capital of 1,000,000 francs to exploit Schoop's welding process.

In alkaline accumulators one of the chief drawbacks when charging is the manner in which the electrolytic froths. Edison finds that if the solution is carefully filtered through purified bone charcoal that this tendency to foam is very much lessened. He supposes that the frothing is caused by the presence of small quantities of animal matter or organisms, and that these are removed by the filtration. *Centralblatt für Accumulatoren und Galvanotechnik*, March 5th, 1908.

Ebstein, *French Patent*, 337855, describes the formation of iron plates by the Planté method. The plates, 95 × 215 cm., are first dipped into sulphuric acid of sp. gr. 1·4 (1 per cent. water to 1 acid) for one hour. They are then dipped into water, and allowed to dry in a warm current of air for one hour. They are then allowed to hang in the air at ordinary temperature for 24 hours, and then placed in a bath of potassium hydroxide, sp. gr. 1·17, between two nickel plates. The nickel plates are separated 3 millimetres from the faces of the iron plate. Now a current of 0·5 ampere is passed for 24 hours. At the end of this time the plates had a discharge capacity of 0·1 ampere hour. If instead of drying the plates with hot air they were subjected to a current of steam before being charged the capacity of the plate increased about 50 per cent. As the potential difference is only 0·1 volt, these plates hardly seem likely to come into use on a commercial scale.

The last number of the *Revue d'électrochimie et d'électrometallurgie* has an article upon the "Electrochemical Industries of Norway." In the first place it is mentioned how well equipped Norway is for electrochemical works, owing to the cheap water power which it possesses. Reference is then made to the production of nitrogenous fertilisers by the electrical oxidation of the atmospheric nitrogen, to the manufacture of calcium carbide, and to the new works of the British Aluminium Co. at Stangfjord. Then there is the Vadheim Electrokemike Fabriken, which manufacture metallic sodium and sodium peroxide. Metallic zinc is also prepared by the electrothermic reduction and distillation of zinc ores. Mention is also made of the proposed works of the North Western Cyanamide Co., Ltd., where calcium cyanamide is to be manufactured.

Heavy Tramway Damages.—On Friday, in the King's Bench Division, a plasterer named J. Neal was awarded £800 damages for injuries received in the accident upon the South Metropolitan Electric Tramways and Lighting Co.'s system at Sutton on Easter Monday, 1907. Another claim arising out of this accident was heard this week, when a coach builder named H. J. Sayer was awarded £300 to himself, £50 for his wife, and £10 for his child.

A compositor named Hiram Pickles, aged 63 years, has been awarded £275 damages against the Halifax Corporation for injuries caused by being thrown off the foot-step of a car as he was entering it. Damages to the extent of £785 were claimed.

ELECTRICAL SCIENCE

British and American

Electric Discharges through Gases.—The second of the course of lectures on this subject was delivered by Prof. J. J. Thomson on Saturday last at the Royal Institution. In the first lecture Prof. Thomson considered the conductivity of the air and the negative charge on the surface of the earth. With respect to the latter some interesting experiments, said the lecturer, would be made by Mr. C. T. R. Wilson to determine whether the charge on a sphere could be made to oscillate by the action of a spark. Short periodic magnetic disturbances had been detected, the period of vibration being only 1-7th of a second, and it was thought that these magnetic disturbances might be due to electric oscillations on the earth's surface, set up by the action of lightning, as 1-7th of a second was the time taken by light to travel round the circumference of the earth. Returning to the conductivity of air, Prof. Thomson showed by experiments that air exposed to radium was ionised and contained a sufficient number of charged particles to cause it to conduct. Röntgen rays had the same effect. The air in the neighbourhood of a flame, an arc, or an incandescent body would also conduct. The conducting particles produced in the air by such ionising agents could be removed by filtering through a glass-wool plug or by electrical means. Thus if the ionised air were passed between two conducting plates, with a difference of potential between them, the negatively charged particles went to the positive plate, and the positively charged particles to the negative plate, the air being thus filtered of its charged particles and rendered non-conductive. In a gas under the influence of an ionising agent, these particles were being constantly produced in pairs; but they also tended to recombine, a negative particle uniting with a positive particle, the resultant particle being neutral and of no use for conduction. A steady state of conductivity was obtained when the number lost by recombination was equal to the number produced by the ionising agent in an equal interval of time. The rate of recombination was proportional to the square of the number of particles present, and the conductivity of a gas thus decreased at a diminishing rate. This rate of recombination had been measured, and it had been found that if there were 1,000 particles of each sign in 1 c.c. of gas, one pair recombined in every second. This was a faster rate than could be accounted for by collision, and therefore the oppositely electrified particles actually attracted one another. With regard to the conducting property of a layer of gas under the influence of an ionising agent, if the potential across the layer were increased, the current increased up to the point when every charged particle produced was being used to convey current. After this the current could not be increased until the gas broke down, and a spark passed. If the thickness of the layer were increased, the current was increased, as more charged particles were available to carry the current, and if the thickness of the layer were doubled, the maximum current (*i.e.*, the current when all particles produced were being used) was doubled. The maximum current was proportional to the mass of the gas between the electrodes. The lecture was illustrated by a series of delicate experiments.

Discharge of Electricity from Pointed Conductors.—In the February number of the *Physical Review*, J. Zeleny gives the numerical results and a general account of his experiments on the discharge from steel needle points or conical points. Positive and negative discharges are considered, and the relations between current, voltage, minimum potential and diameter of the points, are studied. His preliminary experiments showed that selected commercial sewing needles behaved in the experiments in a consistent manner; but the electrical data proved to be a function both of the diameter of the point and of the angle of taper towards the point. The author reduces his results to air temperature 22° C. and barometric pressure 74 cm., and gives many tables and curves enabling any future experimentalist to compute the discharge potential and current from the dimensions of the needle to be used. Some of the results can be expressed by formulæ. For instance, if V is the applied voltage, M the minimum voltage required to start a current, and d the diameter in millimetres of the point of an ordinary needle (angle about 12°), then the positive current C is given in amperes by

$$C = 2{\cdot}58 \times 10^{-13}(1 + 0{\cdot}519d)V(V - M)$$

for voltages between 3.000 and 9.000. In this formula M, the minimum potential required to start a current is represented by the relation

$$M = 2590 + 4750d$$

where d has the same meaning as before.

A similar formula is given for the negative discharge to a plate at the same distance 1·5 cm. as the above experiments on positive discharges, but the experimental results accord less closely with this formula. Another series of experiments on carefully prepared conical brass points of exactly 12° taper, gave, under the same circumstances as used with the needles, the following formula for the positive discharge :—

$$C = 2{\cdot}49 \times 10^{-13}(1 + 0{\cdot}176d^3)V(V - M),$$

where, it will be noticed, the diameter of the end of the cone is raised to the third power. The range of this diameter in the cases investigated by the author was from 0·060 mm. to 1·09 mm. Here $M = 1980 + 5200d$. The negative discharge was too irregular to yield a formula. Incidentally the author observed, when working with steel needles, that tufts of iron oxide formed at their tips when the positive discharge was occurring. The formation of oxide was much smaller in the case of the negative discharge.

Continental

Electrical Measurement of Small Lengths.—In the course of some work in standardising an electrodynamometer for Professor Lippmann, A. Guillet noticed the extreme delicacy of the instrument for any change of mutual position of the coils. This led him to an electric method of measuring small displacements, particulars of which are given in the *Comptes Rendus* for March 2nd. A flat coil C is mounted midway between two flat coils A and B, all three coils having their axes in the same line. When A and B are strictly equal and opposite, the mutual potential of $A+B$ and C is zero. Any slight displacement of C produces a finite mutual potential Δm and induces a current in C. The induced current is proportional to the inducing current, to its frequency, to the conductivity of C, and to Δm. Displacements may be readily compared by reducing the induced current to a standard value by means of resistances. The displacements are then proportional to the resistances so introduced. The sensitiveness appears to be almost unlimited. With an inducing current of 0·3 ampere and a frequency 10, and with a resistance of 100 ohms, the author obtains a deflection of 30 cm. on the scale for every micron (0·0001 cm.) traversed. C is rigidly attached to the structure whose expansion or displacement is to be measured.

Counting Alpha-Particles with the Spinthariscope.—Crooke's spinthariscope has been put to a novel use by E. Regener, who communicates the result of a census of α-particles to the *Verhandlungen* of the German Physical Society for February 15th. He conceived the idea of counting the impinging particles which produce the appearance of a sparkling midnight sky, and comparing the number so obtained with that calculated from other data. In this preliminary report, he shows that a satisfactory agreement is arrived at. He used a polonium preparation as a source of α-rays, and a zinc sulphide screen, magnified 60 times and faintly illuminated, as a detector. A surface only a few mm. in diameter was picked out by means of a screen, and the detector was so adjusted that only one impact had to be recorded every second or two. The counting was done by means of a Morse recorder afid a stop-watch. In one such experiment, in which the surface was 0·325 sq. mm., and the distance 1 cm., 393 impacts were observed in 462 seconds. The total number of α-particles emitted per second by the preparation ranged from 1,511 to 2,281. The saturation current indicates 2,200 such particles, probably as valent helium atoms. The author hopes to count the particles electrically by means of a string electrometer.

Wave Length of Roentgen Rays.—The new and somewhat revolutionary atomistic conception of energy developed by Planck, according to which all quantities of energy are multiples of a quantity which is numerically equal to the energy of charge of a single electron, has already proved fruitful in photoelectric phenomena. It is now applied by W. Wien to an interesting calculation of the wave-length of Roentgen rays, and the results are given in No. 5 of the Göttingen *Nachrichten*. According to Planck, the elementary quantity $\epsilon = hc/\lambda$, where h is the radiation constant ($6{\cdot}548 \times 10^{-27}$ rays per second), c the velocity of light, and λ the wave length of the radiation. Another value of ϵ is the kinetic energy of an electron constituting a secondary X-ray, and generated by a Roentgen pulse. This must, if Planck's law is correct, be equal to the energy of the pulse itself, and so we get the relation $\lambda = 2hc/mv^2$. All the constants of this equation are known. For a velocity $= 8 \times 10^9$, and a specific charge $e/m = 4{\cdot}69 \times 10^{-10}$, the wave-length λ comes out as $6{\cdot}79 \times 10^{-9}$ cm., which agrees fairly well with Hagn and Windt's diffraction value $1{\cdot}3 \times 10^{-8}$ cm. Obviously, only the fastest secondary rays must be taken into account.

THE INTERNAL STRUCTURE OF METALS

A LECTURE on the above subject was delivered on Tuesday, March 10th, before the Manchester Section of the Institution of Electrical Engineers by Mr. W. Rosenhain, Superintendent of the Department of Metallurgy in the National Physical Laboratory. The lecturer began by explaining the manner in which materials are examined under the microscope, briefly describing the methods of grinding, polishing, and etching specimens and the modes of illumination which are used, and went on to describe the typical crystalline structure of a pure metal. The manner in which a molten metal solidifies, and the growth of mutually interlocking and interpenetrating crystals from numerous centres of crystallisation in a cooling metal, were then dealt with, and in this connection the lecturer explained how largely the mechanical properties of a metal depended upon the manner in which these crystals grow, thereby explaining the influence of such factors as casting temperature and the presence of minute quantities of foreign bodies, occurring either at impurities or purposely added. The typical structure of binary alloys was then discussed; the general character of the "eutectic" body frequently found in such binary alloys was explained, and its influence upon the mechanical properties of the alloy was described. Passing on to the subject of the mechanical deformation and ultimate fracture of metals, the lecturer described the observations made by Professor Ewing and himself some nine years ago, which resulted in the discovery of "slip-bands" and a recognition of the manner in which metals undergo deformation by the slipping or sliding of the elements of each crystal over one another, each of the crystals of the metal thus accommodating itself to the new shape imposed upon it by the circumstances of the deformation. In connection with the subject of slip bands, Mr. Rosenhain referred to the semi-plastic condition, which, in iron and steel, follow upon plastic deformation; Muir's work on the recovery from this state produced by exposure to the temperature of boiling water was referred to, and from these facts an explanation was advanced of the causes which lead to the well-known phenomena of fatigue in edge tools, and the recovery of their cutting power after rest. In the last part of the lecture, the various modes of fracture of iron and steel under tension, shock, bending, and alternating stresses were described, and the microscopic features of the fractures illustrated by a series of sections of actual fractures, also obtained by the aid of the electro-embedding process. The lecturer laid great stress on the importance of the systematic investigation of fractures, more particularly of failures occurring in actual practice, since in that way the most useful information could be obtained as to the characteristic behaviour of the materials under various circumstances not readily reproduced in laboratory tests. Special reference was made to the manner in which metal fails under the effect of alternating stresses; the crystalline appearances of the fractures produced in this way was explained on the basis of deformation by slip, and the view that vibration or alternating stresses could cause metal to "become crystalline" was characterised as an entirely groundless and most improbable assumption.

The microscopic study of metals might, he said, find some direct electrical applications; the connection between the microstructure of alloys and their electrical resistance and their resistance temperature coefficient was given as one instance, while in another direction it was pointed out that there was certainly some connection between the magnetic properties of iron and its micro-structure, material showing high permeability and low hysteresis losses generally having a large crystalline structure: there appeared to be some resistance to the magnetic flux at the inter-crystalline junctions, but this was a subject deserving of much further investigation before any definite conclusions could be reached.

METALLIC FILAMENT INCANDESCENT LAMPS

AT a meeting of the Electrical Contractors' Association, on Thursday last, Mr. L. Gaster read a short Paper on Carbon and Metallic Filament Lamps. Mr. Gaster commenced by saying that many years ago it was realised that a higher working temperature for the filament was necessary in order that a larger proportion of rays from the violet end of the spectrum should be emitted. The carbon filament could not stand high temperatures, and, moreover, was seriously affected by fluctuations in the applied voltage. By employing a high temperature in the process of manufacture, the graphite filament, which was a slight improvement on the carbon filament, had been produced. The first commercial metallic filament was the osmium filament, but this was both expensive and difficult to manufacture. The next to come to the front was the tantalum filament, and this metal had the advantage that it could be drawn out to a fine wire. There were now on the market 16 c.p. tantalum lamps which consumed only 1·5 to 1·7 watts per candle, and using these lamps on alternating-current circuits of 50 cycles frequency only reduced the life to about 10 per cent. below that on a direct-current circuit. The next lamp was the Tungsten or Wolfram lamp, for which there were three distinct manufacturing processes. These lamps were suitable for either alternating or direct-current circuits, but as the filament was soft at high temperatures, the lamps must burn in a vertical position. One of the latest developments in lamp manufacture was the Z filament (Zircon Wolfram) lamp; the filaments in this lamp were kept under tension by spiral springs of tungsten, and would burn in any position. A 35-c.p. lamp of this type consumed only 1 watt per candle, and was suitable for either alternating or direct-current. With regard to the economy to be obtained by the use of metallic filament lamps, Mr. Gaster said that if the price of electricity were less than 2d. per unit, it was not economical to use metallic filament lamps, but with a charge of 5d. per unit, for example, the extra cost of the lamps would be compensated for in less than 100 hours. In conclusion, Mr. Gaster referred to the advisability of using lamps of not more than two voltages in one installation when lamps in series were necessary, and also to the need of suitable shades and fittings to harmonise with the new lamps.

In the discussion which followed the Paper, the Chairman, Mr. C. L. Troup said that it was his experience that no metallic-filament lamp would burn at an angle. With regard to shades, he thought that the old-fashioned gallery with three screws and removable shades was better than the screwed-on shade. Mr. Rawlings referred to the unnecessary use of high candle-power lamps where small candle-power lamps would do. Mr. Rashleigh Phipps said that he had found 2 or 3 per cent. overrunning had serious effects on metallic-filament lamps, and recommended using 105 volt lamps on 100 volt circuits where the voltage fluctuation was bad. Mr. E. L. Berry alluded to the necessity of using a larger section of conductor when wiring for low voltage lamps, on account of the increased effect of a drop in voltage, and the larger current taken.

CATALOGUES AND PAMPHLETS RECEIVED

EXHIBITION STANDS AND LIGHTING.—A booklet from the Franco-British Electrical Co. illustrates a system of decorative electric lighting, which consists of crystal festoons and fittings arranged to take lamps of small candle-power. The arrangement is particularly adapted to exhibition stands, &c.

PORTABLE WATTMETERS.—A new list has been issued by the Union Electric Co., of portable wattmeters of the moving-coil type of Messrs. Hartmann & Braun's manufacture. These instruments are suitable for either continuous or alternating currents, and in most cases are arranged for more than current range. A dead-beat action is secured by the use of an air-damping arrangement, and a conveniently arranged mirror under the scale avoids parallax errors. A series of suitable resistances for the pressure circuit is listed, including special star-connected resistance for obtaining an artificial neutral point for three-phase measurements.

SMALL TRANSFORMERS FOR METALLIC FILAMENT LAMPS.—A leaflet from Messrs. Johnson and Phillips gives particulars and prices of this firm's small transformers for metallic filament lamps, which were described in Electrical Engineering, March 5th, page 354.

SWITCHES.—Messrs. A. P. Lundberg & Sons announce in a newly-issued leaflet that after considerable experiment they have adopted a combined construction of mica and vitreous porcelain for the insulation of the current-carrying parts of their well-known "Pivot" switches, which has several advantages over the system previously employed.

Obituary.—We regret to have to announce the death at Bournemouth, on Saturday last, at the age of 81, of Mr. William Ormiston Callender, the original founder of the well-known firm of Callender's Cable & Construction Co. The late Mr. Callender was born at Leith, but settled in London in 1866. He was at that time connected with the paving industry, and as manager of the Val de Travers Co. was instrumental in introducing asphalte for street-paving in London. In 1879 he patented an insulating material in which Trinidad bitumen formed the chief ingredient, and this material has become widely known as a dielectric for underground mains, under the name of "vulcanised bitumen." The Callender's Bitumen Telegraph & Waterproof Co., of which the present company is the successor, was founded in 1882 to develop this invention. Mr. W. O. Callender ceased to take a part in the working management of the company's affairs in 1893, but remained an active member of the Board until 1903, when he resigned his seat as director, but was apointed special director of the company. The funeral took place on Tuesday.

A NEW UNIVERSAL PHOTOMETER

A NEW form of portable photometer, adapted for measurements both of luminous intensity and illumination, which has been designed in America by Dr. C. H. Sharp and Mr. P. S. Millar, is described in the *Electrical World* (New York).

A plan and elevation of the instrument, showing the interior arrangement, is given in Fig. 1. The body of the instrument is a hardwood box about two feet in length, having a hinged

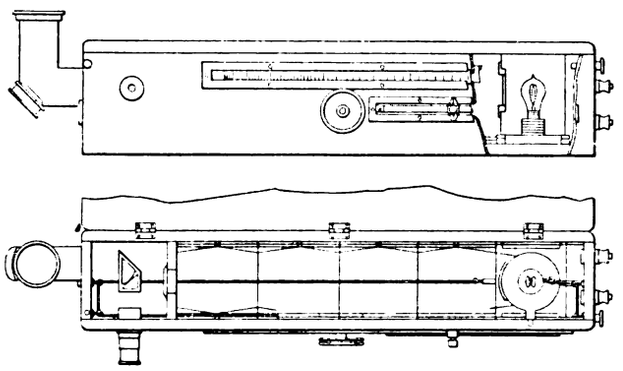

FIG. 1.—SIDE ELEVATION AND PLAN OF PHOTOMETER.

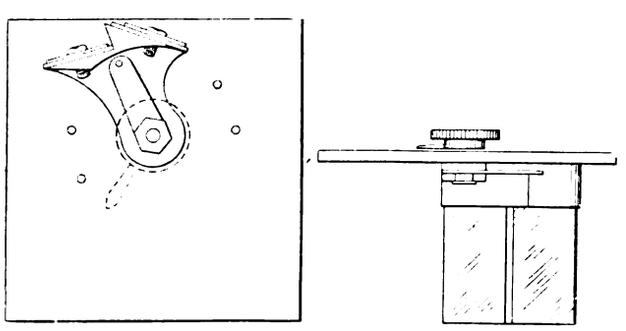
cover so that the entire interior is accessible. The movable part is the comparison lamp, and not the photometric device. The lamp is mounted within a circular metal housing, and is carried on a platform arranged to slide in a track lengthwise of the box. The movement is effected by means of an inelastic cord which passes around pulleys and cones to a drum which can be turned by a large external knob. The variable distance method has the great advantage that its indications depend upon a known law, and that consequently a scale can be made from calculation and not as a result of various trials. The scale from which the indications of the photometer are read consists of translucent celluloid, and is set in a longitudinal opening in the side of the box. In order to prevent external light from having access to the interior of the box, this scale is covered with a long shutter, which can be opened by means of an external knob at the rear of the box. To facilitate taking readings in dark places, a hole is cut in the side of the housing carrying the comparison lamp, so that when the shutter over the scale is raised, the light from the lamp falls on the scale and illuminates it brightly, and the pointer, being inside the box, casts a shadow on the brightly lighted scale. The light from the comparison lamp falls on a milk glass plate, which fills a window in the partition near the end of the box.

Errors due to stray light reflected from interior portions of the instrument, which are difficult to prevent, even by lining the apparatus with black velvet, are avoided by the use of a very simple system of moving screens, which are shown in



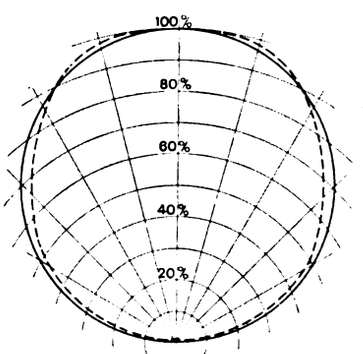


FIG. 2. DIAGRAM OF SCREEN SYSTEM.

Fig. 2. The screens are of fibre, of such size as practically to fill the box. They have apertures sufficiently large to permit the rays of the lamp to pass unobstructedly, and are supported by two longitudinal brass rods, being attached to each other and to the lamp carriage by light cords. When the comparison lamp advances, its housing pushes the screens successively along ahead of it, and when it recedes, the cords pull the screens one after the other into their original position.

The photometric device is a modified form of the Lummer-Brodhun arrangement. By the addition of another totally reflecting surface, rays from opposite directions are brought to the sight tube. The elbow tube at the end of the box has a number of important functions to perform. It fits friction-tight on a collar fastened in the end of the box, and hence may be turned about a horizontal axis and set at any angle, which angle is indicated on a semi-circular scale on the end of the box. The use of a tube of this description furnishes the simplest means of measuring illumination or light coming from any direction. In the elbow of the tube is fixed a reversible plate, one side being a diffusely reflecting surface used in the measurements of candle-power, and the other a mirror used in connection with a test plate on the end of the tube for measuring illumination. In measuring candle-power, the diffusely reflecting surface is turned toward the inside of the tube, and the end of the elbow tube is open, the tube serving to screen off stray light from the plate. The distance between the plate and the source of light must be known.

The photometer being portable and the elbow tube adjustable to any angle, this arrangement lends itself to determinations of the vertical distribution of luminous intensity of light sources, and is also applicable to the measurement of the candle-power of street lamps, either close at hand or at a considerable distance. To measure general illumination, the translucent illumination test plate is slipped on to the end of the tube, and the plate at the elbow is reversed, making its mirrored side effective. The illumination on any required plane can then be measured, the light having unobstructed access to the test plate. It has been found that the test plate of translucent glass, ground on its upper surface so that its power of regular reflection is

Theoretical Curve (full). Curve for Test Plate (dotted).

FIG. 3.—CURVE SHOWING ERROR OF TEST PLATE.

destroyed, is well adapted to the purpose. The criterion for the complete diffusion effect of the plate is that its brightness shall vary directly as the cosine of the angle of incidence of the light upon it. The deviation from this law is shown by the curve of Fig. 3. The error so introduced in the measurement of diffuse illumination is ordinarily negligible.

The scale may be an equal-part scale, or a direct-reading scale. It has been found to be most convenient to make the scale direct-reading in foot-candles. The same scale is equally applicable to the measurement of illumination and of candle-power. The foot-candle scale in question has a range from 0·4 to 20 foot-candles. This range would, of course, be increased considerably by using a lamp of different size, but the range given with any one lamp cannot be considered sufficient to meet all the conditions which are present in practical work. The change from one comparison lamp to another is an inconvenient operation. Recourse has been had, therefore, to the use of absorbing screens. Two of such screens are used, one of which transmits substantially 10 per cent. of the light falling upon it, while the other transmits only 1 per cent. of the light. These two screens are attached to a movable holder, which is not indicated in Fig. 1, but is shown in detail in Fig. 2. By turning the milled head, which is exposed when the cover of the photometer box is lifted, either screen may be interposed between the prism and the milk glass window, or between the prism and the elbow tube, or both screens may be turned to such a position that they intercept no light. Evidently, when the screens are used, the total range of measurement, with but one comparison lamp, is from 0·004 foot-candle to 2,000 foot-candles, within which range all measurable lights and illuminations can be said to fall.

"ELECTRICAL ENGINEERING" PATENT RECORD

(This Patent Record is compiled by our own Editorial Staff and is Strictly Copyright.)

Specifications Published March 12th, 1908

A full list of these was published in our last issue. The following are abstracts of the more important specifications.

Names in brackets indicate communicators of inventions from abroad.

1907 Patents

4,031, V. A. FYNN. Improvements in the starting and operation of single-phase induction motors of the split-phase type, with two or more inducing windings. Former methods of obtaining the necessary phase displacement between the applied E.M.F.'s for the two or more windings, such as the insertion of inductance or capacity in series with one winding, only permitted of a displacement of less than 90°. According to the present invention, a phase-displacing circuit is provided, containing two or more elements of differing impedance, one of which is an inducing winding of the motor. An E.M.F. derived from one of these elements and differing in phase from the E.M.F. of the supply is combined, either directly or indirectly, through a variable ratio transformer, with the E.M.F. of supply, and by this means an E.M.F. of a suitable value and with any desired phase displacement from the supplied E.M.F. can be obtained, and applied to the other inducing winding of the motor. The induced member may be an ordinary short-circuited armature, a squirrel-cage rotor, or an armature with slip-rings and external variable resistances. The starting torque and power factor of the motor are improved by the above method of starting. Several modifications are described in the specification. Sixteen claims, eighteen figures.

4181, BRITISH THOMSON-HOUSTON CO. (*General Electric Co.*) A method for the prevention of electrolysis by alternating currents, of iron pipes, lead-covered cables, &c., buried in the earth. For instance, in the case of the leakage currents of railway systems, the negative half-wave of the alternating current does not completely neutralise the electrolytic effect of the positive half-wave, and electrolytic corrosion results. The present method consists in superimposing upon the alternating current a uni-directional current of such intensity (about 1·5 per cent. of the main alternating current) as to neutralise completely the electrolytic effect. The negative wave is thus made slightly larger than the positive wave. The auxiliary uni-directional current can be obtained from the main supply by means of a mercury valve, rotary transformer, or other suitable device, or from a different source of supply as a battery. Six claims, one figure.

4,211, CROMPTON & CO., MACFARLANE, AND BURGE. A motor generator for transforming continuous current to higher or lower potential. The machine consists of a single armature with a ring winding, and a single commutator. Auxiliary brushes on an axis at right angles to the axis of the main brushes (in a two-pole machine), are provided, and these auxiliary brushes are connected together. The lower pressure current is taken out from or fed in at one main brush, and the auxiliary brush connection. In order to obtain a symmetrical distribution of the potential round the commutator, the main poles are split into two parts, each part being provided with a winding. The armature flux has no path through the yoke of the machine and the necessary symmetry of the flux and potential is obtained. Applied to the case of a rotary converter, the ring-wound armature is provided with slip rings to take in or give out the alternating current. The poles are split as described above. In both the above cases the field circuit providing the motoring flux is quite separate from the field circuit providing the generating flux, and in the case of the rotary converter, the direct-current voltage can be regulated by varying the generating field, the power factor on the alternating-current side being kept at unity by making an inverse variation of the motor field, as it is only necessary that the total flux should remain constant. One claim, four figures.

5,506, B. T. LAMME. An alternating-current series commutator traction motor, supplied with current from the low-voltage winding of a transformer, has a local circuit of low resistance and under certain conditions the motor may act as a direct-current generator and send current through this circuit. In order to prevent this action, the series field winding is shunted with a choking coil of high inductance and low resistance compared with the series field winding. Any direct-current that is generated flows through this shunt and not through the series winding, and consequently does not produce a strong enough field to cause any considerable generating effect. If the resistance of the series field winding is very low, a resistance can be inserted in series and the shunt connected across both. By providing the choking coil with taps, it can be used as a means of reducing the regenerating action of the motor when the car is running down hill. This regulating action can be made automatic, by causing the current generated (and which is returned to the line) to flow through a solenoid, which solenoid operates a plunger increasing a gap in the choking coil core with increasing current. The inductance of the choking coil is decreased, and more current is shunted from the motor series field. Four claims, five figures.

Specifications Published To-day

The following Patent Specifications will be published to-day, and will be on sale at the Patent Office Sales Branch, 25 Southampton Buildings, London, E.C., at the price of 8d. each, post free. The number and year of the patent should be quoted on the order.

Summaries of the more important of these patents will appear in our next issue.

1907 Patents

4,123, STONE. Systems for wireless telegraphy.
4,333, WEBB. Selective continuous wave telegraphy.
4,397, ECKSTEIN & HEAP. Circuit breakers.
4,425, SCOTT. Time limit circuit breakers.
4,470, LAUTENBACH. Electric power plants.
5,012, COOK. Electrical protective apparatus.
5,087, SUTTON & SUTTON. Automatic fire alarms.
5,154, COWPER-COLES. Manufacture of projectiles and other hollow objects.
5,506A, LAMME. Operation as generators of alternating current series commutator motors.
5,508A, LAMME. Operation as generators of alternating current series commutator motors.
5,513, SIEMENS BROS. DYNAMO WORKS AND BOLTON. Relays or cut-outs.
7,663, TAYLOR. Vibrators for siphon recorders.
7,718, SMITH. Fire and temperature alarms.
7,982, BLACKMORE. Electric magnetic separators.
8,284, THIELLET AND DENARD. Electric accumulators.
9,912, HAWKINS. Record-slips for meters.
13,354, DRIVER. Method of attaching filaments to the leading-in wires of incandescent lamps.
16,447, COREY. Switch mechanism.
17,094, DYMOND (*American Electric Chain Co.*). Process for the manufacture of chain.
17,097, ALLGEMEINE ELEKTRICITÄTS GES. Switch mechanism for electrically-propelled vehicles.
18,403, STOKES. Surface traversers for use on railways and tramways.
18,681, SIEMENS BROS. DYNAMO WORKS AND HOLMES. Electric arc lamps.
18,843, GUDGEON. Electrical switch applicable to railway signalling.
19,340, SIEMENS & HALSKE AKT.-GES. Signalling telegraphs.
19,558, SIEMENS BROS. & CO. (*Siemens & Halske Akt.-Ges.*). Electrical locking apparatus for railway signalling.
20,600, HEITMANN AND YOUNG. Wedges for the slots of dynamo-electric machines.
21,467, ELEKTRIZITÄTS AKT.-GES. VORM. SCHUCKERT & CO. Maximum demand indicators.
22,722, ASKLING. Ignition devices for reversible internal-combustion engines.
22,833, CONRAD. Armature windings.
23,319, HARTMANN & BRAUN AKT.-GES. Frequency meters, speed indicators and relays.
24,923, DUGASZ, KALDOR AND SZENDE. Telephonic communication between railway trains.
26,622, CUMONT & COMPAGNIE DE SIGNAUX ELECTRIQUES POUR CHEMINS DE FER. Railway signal mechanism.

1908 Patent

796, AUBERT AND AUBERT. Electrically-controlled apparatus for igniting and extinguishing lamps.

Complete Specifications open to Public Inspection before Acceptance.

1907 Patent

26,642, CREIGHTON. Devices for protecting electrical systems.

1908 Patents

2,824, FALKENTHAL. Apparatus for producing ringing currents in telephone systems.
3,159, FREY. Link-suspension device for incandescent bodies.
3,592, GRAMMONT AND ROUTIN. Electric servo-motors.
3,701, "POLYPHUS" ELEKTRICITÄTS-GES. Electrical method of transmitting photographs.
3,986, ALLGEMEINE ELEKTRICITÄTS-GES. Electrically-driven rolling-mills.
4,052, HERRENSCHMIDT. Processes of melting in electric furnaces.

Expiring Patent

The following Patent expires during the current week, after a life of fourteen years:—

5,863 of March 21st, 1894. HENRY REASON. Fuse boxes for supply mains, so constructed that when the lid covering the box or compartment containing one fuse is opened, the other lid covering the box containing the fuse on the other side of the mains cannot be opened. One claim, seven figures.

THE PROPOSED HOME OFFICE REGULATIONS

(Special Report. Strictly Copyright)

THE inquiry into the proposed Home Office Regulations respecting the use of electricity in factories and workshops was resumed before Mr. Swinburne on Monday at Caxton Hall, Westminster. As has been previously reported in our columns, objections have been raised to the whole principle of the Regulations, and also to numerous points of detail. During the previous sittings much time was devoted to the argument that electrical undertakers under statutory powers should be exempt from the Regulations, and the proposed rules as to the dimensions of switchboard galleries and passages and as to the compulsory use of no-voltage releases for alternating-current motors were hotly opposed. On the resumption of the inquiry on Monday some arguments were heard with regard to the exemption of docks, and then Mr. A. P. Trotter, Electrical Adviser to the Board of Trade, gave evidence.

MONDAY, MARCH 16th.—FIFTH DAY.

Mr. Vesey Knox, K.C., on behalf of the Mersey Docks and Harbour Board, referred to exemption (*b*), viz.: —"Nothing in regulations 7, 8, 9, 10, and 28 shall apply in electrical stations to any circuit, conductor, or cable used for conveying electrical energy for public supply or traction, under statutory powers or for railway purposes." His clients wished respectfully to point out that there was no reason why the words "or for railway purposes" should not be made applicable to the railway works in connection with docks, especially in the case of a statutory dock undertaking, such as that of the Mersey Docks and Harbour Board. There was no real difference between a railway shunting yard on dock premises and upon purely railway premises; nor was there any difference with regard to cranes, &c. As a matter of law, dock premises did not come within the Factory Acts, unless part of them were used for making goods or something of that sort, and he would like to bring to the Commissioners' notice regulations dated August 24th, 1906, and made under Section 149 of the Factory Act of 1901, relating to the use of locomotives and wagons on lines and sidings used in connection with premises coming within the Factory Acts. In these regulations dock premises were expressly excluded, and he thought that if the same exclusion could not be made in these regulations, at any rate the dock premises should be given the same advantages as railways.

Mr. Swinburne asked if the exemption referred to only included rolling-stock, or did it include other things?

Mr. Vesey Knox thought it was quite clear that the exemption included cranes, capstans, &c., as the words "or for railway purposes" had been added apparently to have a wider meaning than "traction under statutory powers," which would have covered purely traction purposes.

Mr. Downing, on behalf of the Barry Railway Co., suggested the addition of the words, "railway or dock purposes" at the end of the exemption. His company owned a large number of docks, and he concurred in everything Mr. Vesey Knox had said.

Mr. Vesey Knox thought his suggestion might, at any rate, be confined to statutory dock undertakings.

Mr. Gray, on behalf of the Home Office, promised to consider the suggestion.

Mr. A. P. Trotter, Electrical Adviser to the Board of Trade, gave evidence as to overlapping between the present Board of Trade regulations and the proposed regulations of the Home Office. He said he was authorised by the Board of Trade to suggest one or two amendments to the existing regulations with the object of avoiding overlapping.

A new definition would be added to the Board of Trade regulations to read as follows:—"In these regulations the expression 'principal regulations' means regulations for securing the safety of the public made by the Board of Trade in. . . ."

At the end of regulation A1 of the Board of Trade regulations the following provision to be added:—

"Provided that these regulations shall not apply to the supply of energy to any factory, workshop, or mine."

Another paragraph would be added to regulation A1 as follows:—

"An extra high pressure supply shall not be given to any consumer's premises other than a factory, workshop, mine, or electric traction works. Where the consumer's premises are an electric traction works, a supply shall only be given with the consent of the Board of Trade, and shall be subject to such regulations as the Board of Trade may prescribe."

Mr. Trotter continuing, said that at present the Board of Trade had to give consent to each individual case of extra high pressure supply, but in future in factories this would no longer be necessary, because the Home Office regulations would have to be complied with. These alterations would, he thought, obviate any overlapping between the two sets of rules.

A number of questions were put on behalf of the objectors. Mr. Vesey Knox pointed out that insulation was dealt with in regulation 6 of the Board of Trade and regulation 2 of the Home Office.

Mr. Trotter did not think there would be any overlapping here. He said there was a certain point at which the jurisdiction of the Home Office and the Board of Trade met, and this point was defined as the consumers' terminals, which were defined in the principal Act.

Mr. Vesey Knox pointed out that it was proposed to apply the Home Office regulations to stations and sub-stations, so that there must be friction between the Home Office and the Board of Trade regulations.

Mr. Trotter said he had regarded the question mainly from the point of view of factories. He confessed that it might be necessary to exclude from the Board of Trade regulations generating stations and sub-stations if they were to become subject to the Home Office rules.

Mr. Vesey Knox: To what, then, would your Board of Trade regulations apply?—They would apply mainly to the distributing mains in the streets, and to the safety of the public in respect of them.

In reply to further questions, Mr. Trotter said he did not think there would need to be any modifications of the Board of Trade regulations with regard to sub-stations, because hitherto the Board of Trade had only dealt with this from the point of view of ventilation and drainage. The plans generally sent to him for sub-stations would not contain any details of switches. He generally told people that the sub-station must be constructed according to the Home Office regulations.

Mr. Vesey Knox: But the Home Office regulations deal with ventilation and drainage also?—These are very important for the employees.

Continuing, in answer to further questions, Mr. Trotter said that it was quite possible that if the Board of Trade found the Home Office regulations insufficient, or *vice-versâ*, the owners of the sub-station might have to do something more, because the two departments were looking after the interests of different sections of the community. He did not think this was necessarily overlapping, because if the owner of the sub-station complied with the strictest regulations he would satisfy both departments. Similarly, on the question of penalties, although Mr. Trotter understood that there would be two supplemental penal provisions, he did not think they would come into conflict.

Some further questions were put by Mr. Vesey Knox and other representatives of objectors, which Mr. Trotter thought took him away from the question of overlapping, and he gave no answer.

Mr. Guttridge, on behalf of the London County Council, asked if it was proposed to make fresh regulations for tramway sub-stations supplying energy for lighting the tramcars. Mr. Trotter said no. In reply to further questions, that such sub-stations would have to comply with two sets of regulations, Mr. Trotter replied that the Board of Trade at present had no regulations for switchboard details.

Mr. Guttridge drew attention to the extra-high pressure regulations of the Board of Trade, which gave the officials of the Board authority to enter and inspect premises. He thought that this would give the Board of Trade officials power to make regulations as to the details of switchboards. Mr. Trotter said that though these regulations might give this power it was never acted upon, as the Board only took into account the safety of the public.

Mr. Morse suggested that the Board of Trade Regulations, in referring to the safety of the public, sufficiently covered the employees.

Mr. Trotter said he could not give a definition of the word "public," but it had not been regarded by the Board of Trade from the point of view of employees hitherto. Mr. Trotter further said that it was not the intention to hand over to the Home Office the authorisation of extra-high pressure supply, and if the amendments which he had suggested permitted of this then some alteration must be made.

Mr. Morse then drew Mr. Trotter's attention to the fact that some years ago an inquiry was held in London at which the dimensions of transformer boxes under the streets were restricted to certain limits. These limits had been approved by the Board of Trade, and in the case of the County of London Electric Supply Co., there had been 160 such boxes constructed. These boxes would not comply with the new regulations, and he wished to know what position the undertakers would be in.

Digitized by Google

seeing that although they did not comply with the regulations they were forbidden to alter them.

Mr. SWINBURNE intimated that he did not think Mr. Trotter could answer this question.

Mr. TROTTER suggested that perhaps in the cases spoken of by Mr. Morse, the Board of Trade had some regard for the safety of the employees, but experience had shown the precautions taken to be insufficient. He had a large number of newspaper cuttings which showed that sub-stations were a very fruitful source of accident.

Mr. GRAY, on behalf of the Home Office, then called further evidence on Rule 12, dealing with no-voltage releases for alternating-current motors.

Mr. E. GARSIDE, Managing Director of Engineering Instruments, Ltd., said that his firm had been making these instruments for some time, and also as a combination of starting switch and stator main switch for alternating-current motors. The smallest sized motor for which they had standardised this apparatus was 50 h.p. The difference in price between a plain hand switch and a switch with no-voltage release for a 50-h.p. 500-volt motor was £5. Hitherto they had mostly been put in coal mines, but a few had been put in factories. His firm only made a completely enclosed switch. For less than 50 h.p., although he had never made a release of this description, he estimated, from his experience with the larger sizes, that the difference in price between a plain switch and one with no-voltage release was £2. His firm had supplied this apparatus for motors from 50 h.p. to 200 h.p., and during the three years they had been supplied he had received repeat orders.

In cross-examination by Mr. Vesey Knox, witness stated that the price for a plain hand switch for a 50-h.p. motor, of the type manufactured by his firm, was about £3, and with the no-voltage release attachment it would be from £8 to £9. These prices were the average selling prices of his firm for the past two years.

Mr. VESEY KNOX said that this price for a plain knife switch was about 200 per cent. more than the Newcastle Co. was in the habit of paying for a perfectly reliable article.

Mr. GARSIDE said that, of course, switches could be obtained at all prices.

In reply to further questions, he said that about 44 of these switches had been supplied during the past three years, 26 of which were for three-phase motors. Most of them had been supplied to electrical contractors and manufacturers, and a good many of them to Messrs. Ernest Scott & Mountain, of Newcastle-on-Tyne. He could not give the names of any collieries in that district, because the collieries were not his clients.

Mr. VESEY KNOX then put a question to witness as to the output of his firm, to which Mr. Gray, on behalf of the Home Office, objected as irrelevant.

Mr. VESEY KNOX said that he regarded this evidence as an attempt to push what he might call an unpractical article with the assistance of the Home Office, and he only wished to show that the firm represented by the witness was not really a large manufacturing firm at all; but he would not press the question.

Questioned by Mr. A. B. Caine on behalf of the London Electric Lighting Companies, Mr. GARSIDE said that he had supplied several to the Union Electric Co. in London, but he could not give the name of any place where one could be seen working. They were supplied to the contractors, and he did not know for what purpose they had been used.

Mr. GRAY, on the question of no-voltage releases, said that having carefully considered Mr. Merz's evidence that probably 95 per cent. of the installations at present existing were safe, without this, it was not fair to make regulations for only 5 per cent., and to make the other 95 per cent. comply with them. The Home Office were willing to alter the second part of Regulation 12 to read as follows:—

"Where necessary to prevent danger, to prevent the automatic restarting of a motor, every electrical motor or group of electrical motors shall be protected by a release which will automatically break the circuit if the current is interrupted, such a release being suitably placed and arranged having regard to the danger to be prevented."

At this point a suggestion was made by the objectors that a conference should be held between the experts on both sides with a view to clearing out of the way many minor points on which all the objectors were agreed. After some discussion, it was decided to appoint a committee of objectors to meet the Home Office experts and advisers, and the afternoon was devoted to a private conference between these. Messrs. Frank Bailey and C. P. Sparks represented the London Electric Lighting Companies and the British Electrical Federation, Mr. C. H. Merz represented the Newcastle Power Companies, the Mersey Docks and Harbour Board, &c., Mr. Cozens-Hardy and Mr. Sillar represented a large number of small public generating stations, in addition to a number of factories and consumers generally, Messrs. W. W. Lackie, H. Talbot, and H. Faraday Proctor represented the municipalities owning generating stations, and Mr. T. Roles represented the Bradford Corporation, the Leeds Chamber of Commerce, and the Yorkshire Electric Power Co. On behalf of the Home Office there were present Mr. J. Hunter Gray and Mr. Raymond Asquith, Mr. B. Arthur Whitelegge, C.B., M.D., H.M. Chief Inspector of Factories, Mr. G. Scott Ram, H.M. Electrical Inspector of Factories, Mr. W. H. Patchell and Mr. J. F. C. Snell.

TUESDAY, MARCH 17TH.—SIXTH DAY.

Mr. GRAY, on behalf of the Home Office, announced that the result of the conference on the previous afternoon was that those concerned had agreed upon certain modifications to the first 11 regulations. We give below the regulations, as amended:—

Regulation 1.—All apparatus and conductors shall be sufficient in size and power for the work they *are* called upon to do, and so constructed, installed, protected, worked, and maintained as to prevent danger *so far as is reasonably practicable.*

The original regulation read "for the work they may be called upon to do," and did not contain the last six words.

Regulation 2.—All cables shall either be covered with insulating material, and further efficiently protected where necessary, or shall be so placed and safeguarded as to prevent danger *so far as is reasonably practicable.*

The last six words have been added.

Regulation 3.—Every switch, circuit-breaker, and isolating link shall be:—(*a*) So constructed, placed, or protected as to prevent danger. (*b*) So constructed and adjusted as accurately to make and to maintain good contact. (*c*) Provided with an efficient handle or other means of working, insulated from the system, and so arranged that the hand cannot *inadvertently* touch live metal. (*d*) So constructed or arranged that it cannot accidentally fall or move into contact when left out of contact.

The word inadvertently has been added.

Regulation 4.—Every switch *intended to be used for breaking a circuit* and *every* circuit-breaker shall be so constructed that it cannot be inadvertently left in partial contact. Every switch *intended to be used for breaking a circuit* and *every* circuit-breaker shall be so constructed that an arc cannot accidentally be maintained.

The italicised words have been added.

Regulation 5.—Every fuse and automatic circuit-breaker used instead thereof shall be so constructed and arranged as effectively to interrupt the current before it so exceeds the working rate as to involve danger. It shall be of such construction or be so guarded or placed as to prevent danger from overheating, or from arcing or the scattering of hot metal or other substance when it comes into operation. Every fuse shall be either of such construction or so protected by a switch that the fusible metal may be readily renewed without danger.

The alteration is merely a verbal one.

Regulation 6.—Every electrical joint and connection shall be of proper construction as regards conductivity, insulation, mechanical strength, and protection.

This regulation is as before.

Regulation 7.—Efficient means, suitably located, shall be provided for cutting off all pressure from every *part of a system as may be necessary to prevent danger.*

The italicised words replace the word "circuit" in the original regulation.

Regulation 8.—It was agreed that, subject to discussion on Regulation 13, this regulation should be altered to read as follows:—

"Efficient means suitably located shall be provided for protecting from excess of current every part of a system as may be necessary to prevent danger."

The regulation is entirely re-written. Originally it specified that every circuit arranged to carry more than 750 watts should be separately protected.

Regulation 9.—Where a conductor of a system is connected to earth, no single pole switch other than a link for testing purposes or a switch for use in controlling a generator, shall be placed in such conductor or any branch thereof.

Originally the regulation read:—"Where one point of a system is connected to earth, no single-pole switch other than a link for testing purposes shall be placed in any cable connected thereto."

Regulation 10.—Where one of the main conductors of a system is bare and uninsulated, such as a bare return of a concentric system, no switch, fuse, or circuit-breaker shall be placed in that conductor, or in any conductor connected thereto, and the said conductor shall be earthed.

There is practically no alteration in this.

Regulation 11.—Every motor, converter, and transformer shall be protected by *efficient means* suitably placed, and so connected that all pressure may thereby be cut off therefrom and from any apparatus in connection therewith, *provided, however, that where one point of the system is connected to earth, there shall be no obligation to disconnect on that side of the system which is connected to earth.*

"Efficient means" replaces the words "switch and switches" in the original regulation, and the last thirty-one words have been added.

The proceedings were adjourned at an early hour to allow of a further conference between the parties in respect of the remaining regulations.

Digitized by Google

WEDNESDAY, MARCH 18TH.—SEVENTH DAY.

Mr. SWINBURNE said he understood the Committee of Objectors and the Advisers to the Home Office had not concluded their consideration of the regulations.

Mr. GRAY handed in a report of the proceedings of the private conference as far as it had gone yesterday, and we give the further amended regulations below. At the same time he corrected part of Mr. W. H. Patchell's evidence concerning no-voltage releases. Mr. Patchell had stated that he had used these for both 440 volts and 2,000 volts. Upon inquiry it was found that these had not been actually used for 2,000 volts, although the apparatus was ready.

Regulation 12.—Every electrical motor shall be controlled by an efficient switch or switches for starting and stopping, so placed as to be easily worked by the person in charge of the motor. To prevent danger through the automatic re-starting of a motor every electrical motor *or group of electrical motors* shall be protected by a release which will automatically break the circuit if the current is interrupted, *such release being suitably placed with regard to the danger to be prevented. Provided that no release shall be required for any motor which has an attendant constantly at the controller of such motor while at work.* In every place in which machinery is being driven by any electric motor, there shall be means at hand for either switching off the motor or stopping the machinery.

The words in italics have been added. The last ten words replace the words "for quickly stopping the motor" in the regulation as originally drafted. This is one of the regulations about which there has been much discussion, in view of the contention that no-voltage releases for A.C. motor switches are unnecessary, and that very few are in use.

Regulation 13.—Every flexible wire for portable apparatus shall be connected in a system either by efficient permanent joints or connections, or by a properly constructed connector. Adequate precautions shall be taken against shock due to leakage or other cause in all places where the person handling the portable apparatus is not insulated from earth. In such places and in any place where the pressure exceeds low pressure, the portable apparatus and its flexible wire shall be controlled by sufficient means suitably located, and capable of cutting off the pressure.

The original regulation specified the use of a switch to control every piece of portable apparatus and its flexible, and that in the case of pressures exceeding low pressure the switches should be double-pole. It is seen that the necessity of a switch in the case of low pressure is dispensed with.

Regulation 14.—The general arrangement of switchboards shall, so far as reasonably practicable, be such that: (*a*) All parts which may have to be adjusted or handled are readily accessible. (*b*) The course of every conductor may, *where necessary*, be readily traced. (*c*) Conductors connected to different systems are kept *well* apart and can *when necessary* be readily distinguished. (*d*) All bare conductors are so placed or protected as to prevent danger from accidental short circuit.

The words in italics have been added.

Regulation 15.—Every switchboard having bare conductors normally so exposed that they may be touched, shall be located in an area or areas set apart for the purposes thereof *or where necessary* suitably fenced or enclosed. No person except an authorised person, or a person acting under his immediate supervision, shall *for the purpose of carrying out his duties* have access to any part of such area.

The words in italics have been added.

Regulation 16.—All apparatus appertaining to a switchboard and requiring handling shall, so far as practicable, be so placed or arranged as to be operated from the working platform of the switchboard, and all measuring instruments and indicators connected therewith shall, so far as practicable, be so placed as to be observed from the working platform. If such apparatus be worked or observed from any other place, adequate precautions shall be taken to prevent danger.

No alterations have been made.

Regulations 17 *and* 18.—The consideration of these regulations was postponed. They relate to the design and dimensions of switchboard galleries and passage-ways, and it will be remembered that they are strongly opposed, especially by the owners of existing electricity works.

Regulation 19.—All *parts* of generators, motors, transformers, or other similar apparatus, at high pressure or extra high pressure, and within reach from any position in which any person employed may require to be, shall be, *so far as reasonably practicable*, so protected as to prevent danger.

The word "parts" replaces the words "all fixed coils, conductors, or terminals" in the original regulation, and the words "similar," and "so far as reasonably practicable" have been added.

Regulation 20.—Where a high pressure or extra high pressure supply is transformed for use at a lower pressure, suitable provision shall be made to guard against danger by reason of the lower pressure system becoming accidentally charged above its normal pressure by leakage or contact from the higher pressure system.

The only alteration in this regulation is an important verbal one.

In order to give an opportunity for the Committee of Objectors and the Advisers to the Home Office to complete their consideration of the regulations, the inquiry was adjourned until Tuesday, March 24th.

LOCAL NOTES

BARNES: *Electricity Charges.*—In a report, the Electrical Engineer recommends that 10 per cent. for lighting be allowed to power consumers. In regard to a suggestion made that the charges for private lighting be reduced by 1d. per unit, the engineer states that if such a reduction was made, there would be £1,542 less income, and he suggested that if a reduction was deemed essential, that it should be only ½d. The surplus gross revenue for 1907-8 was £6,837, and deductions from this left a net amount of £4,191. The amount necessary to meet current expenditure was £1,200, leaving £3,000 to be carried to a reserve fund, the establishment of which he strongly recommended. In the result the Council decided not to make any reduction in the charges, but approved the establishment of a reserve fund, and referred the question of the amount of such fund to the Finance Committee.

BATH: *The Electric Light Works.*—At the last meeting of the Corporation the report of the Electric Lighting Committee stated that, in connection with the application of the Bath Rural District Council for an extension of their Electric Lighting Provisional Order for two years, and a transfer of the powers to Mr. Schenk, representing the Somerset Electric Power Co., objection had been lodged with the Board of Trade. Dealing with the proposal to purchase the Corporation's electricity works by Mr. Schenk, the Chairman of the Electricity Committee stated that it would be impossible to complete the arrangements entered into for the transfer to the undertaking by the date mentioned in the agreement, namely, March 31st. Difficulties had arisen which had necessitated a further interview between Mr. Schenk and the sub-committee, and an alternative proposal had been made, which, if it could be carried out, the committee were of an opinion would be equally advantageous to the Corporation. It had been agreed, however, that the sum of £2,500, which had been deposited by Mr. Schenk, would remain the property of the Corporation.

BIRMINGHAM: *The Tividale Tramcar Accident.*—Col. Yorke held an inquiry at the Oldbury Council House on Thursday into the recent accident upon the system of the Birmingham and Midland Tramways, Ltd., when a car overturned when crossing the points at Tividale (ELECTRICAL ENGINEERING, MARCH 5th, p. 367). During the course of the evidence the inspector stated that he was unable to attribute the cause of the accident to the condition of the permanent way. No technical evidence was called.

BRIGHTON: *Shoreham Harbour and the Electricity Works.*—The Shoreham Harbour Trustees at its last meeting discussed the question of the protective measures which it considered the Corporation should take to protect the foreshore of the harbour, in consequence of the operations of the Corporation in connection with the electricity works. It was pointed out that the Corporation had weakened that part of the beach by taking shingle for the foundation of the Southwick works, with the result that part of the beach had given way, and the sea had come over the crown. The Harbour Master expressed the opinion that very much more substantial work should be done than up to the present, and suggested the use of groynes.

CITY OF LONDON: *Tramways.*—At the meeting of the Court of Common Council on Thursday, the following letter from the Clerk of the London County Council was read:—"The Council understands that the City Corporation has under contemplation the rebuilding of Southwark Bridge. The Council feels that this work, if undertaken by the Corporation, would afford a very favourable opportunity for taking the tramways across the bridge from the present terminus in Southwark Bridge Road to a point a little north of the river. By this means important additional travelling facilities would be provided—particularly for those wishing to reach parts of the City which would be thus served. The Southwark Bridge tramways are already largely used by persons travelling to and fro from South London to their places of work in the City, and the present position of the tramway terminus south of the river is a source of very real inconvenience to those passengers. In view of these facts, the Council hopes that the Corporation will be so good as to take into consideration the question of the extension of the tramways as proposed, simultaneously with the reconstruction of the bridge, if decided upon. The Highways Committee of the Council have the matter before them, and they would be glad of an opportunity of attending before the Corporation, or one of its committees, on the subject by depu-

Digitized by Google

tation, and explaining the Council's views thereon more fully. It would be a great convenience if you would kindly inform me at an early date whether the Corporation will grant an interview to the committee to discuss the question." The letter was referred to the Bridge House Committee, who were empowered to confer with the Highways Committee of the London County Council.

DUNDEE: *The Stannergate Power Station.*—Mr. H. Richardson, the Electrical Engineer, reports that the extra high tension mains from the Dudhope Crescent Road station to the central area of the city, have been completed, whilst those from the new station at Stannergate will be laid shortly.

DUNFERMLINE: *Electric Lighting.*—In consequence of the refusal of Sir Alexander Kennedy to act as Consulting Engineer to the Town Council, owing to his advice to dispose of the Provisional Order to the Fife Electric Power Company not being acted upon, the Electric Lighting Committee recommends that Mr. O. F. Francis, Electrical Engineer to the Kirkcaldy Burgh Council, be appointed to act. A motion disapproving of this recommendation, and urging that a vote of the ratepayers be taken to decide the question as to whether the Council shall erect a generating station or transfer its Provisional Order, was ultimately carried.

EALING: *Tramways.*—Councillor Armriding, the originator of the proposed scheme of municipal tramways, has stated that he has come to the conclusion that the trams would be neither profitable nor practicable.

EDINBURGH: *Edinburgh Exhibition.*—It is stated that a proposal will be made to the Corporation for laying a double line of electric tramway between the terminus of the present cable line at Murrayfield and the Edinburgh Exhibition. The proposal is being made by the owners of the patent of the Cope shallow-conduit system, who express their willingness to lay down the line free of cost, to work it during the Exhibition, and, if desired, remove it at the close. The Edinburgh Tramways Co. has been negotiated with, and are prepared to arrange for through booking.

HANDSWORTH: *Purchase of Tramways.*—The Urban District Council has served notice upon the City of Birmingham Tramways Co., requiring the company to sell to the Council the tramways in Handsworth. A sub-committee of the Urban District Council recommend that arbitration be resorted to for settling the price to be paid for the undertaking, and that the Board of Trade be asked to appoint a referee.

JOHANNESBURG: *The Gas Driven Generating Station.*—It seems, says the *British and South African Export Gazette*, that an effort to remedy rather than reject the giant producer-gas power plant at Johannesburg has been hindered by premature publicity. The Council had under consideration a scheme by which Messrs. W. and J. Beardmore, the guarantors, were to be allowed to form two companies, one for lighting and one for power, and the former, with a capital of £250,000, was to take over the plant on payment of £175,000, of which £125,000 would be in debentures. This company was to guarantee to commence the restoration of the plant within six months, to bring it to within 25 per cent. of the contract stipulation within two years, and to supply the Municipality with 10,000,000 units per annum, while also reserving the right to supply current to the mines. The power company was to have a capital of £200,000, would guarantee the £125,000 debentures, and would erect and equip a power station. The whole scheme was to be without prejudice to the Municipality's claim on the contractors and guarantors. The details of the scheme were being kept strictly private, when the *Transvaal Leader* astonished the Council and public alike by printing a lengthy account of it, which the Special Committee alleged to have been divulged by one of themselves, and forthwith resigned by way of protest. A new committee has now been appointed, and the scheme, if it be adhered to, needs a great deal of elucidation, and will no doubt, be the subject of thorough discussion by the authorities and the ratepayers before it is adopted.

KIRKINTILLOCH: *Tramways.*—The question of approaching the Glasgow Corporation for an extension of the tramway system into Kirkintilloch, was raised at a recent meeting, and the Clerk to the Council was instructed to write to the Tramways Committee of the Glasgow Corporation on the subject.

LANCASHIRE: *New Tramway Project.*—Messrs. Vaudrey, Oppenheim, and Mellor, solicitors for the promoters of the proposed new tramway between Preston, Chorley, Adlington, and Horwich, coupling up there with the Bolton system, are negotiating with the Bolton Corporation for a supply of current in bulk at the Horwich end of their system.

LEEDS: *Tramwaymen's Hours.*—A deputation of the Amalgamated Society of Tramway and Vehicle Workers has waited upon the Consultative Committee of the Corporation to discuss the men's demand for a reduction of six hours per week in the hours of labour, without any reduction in pay. The Tramways Committee, as a compromise, recently offered a merit badge for seven years' service and afterwards, carrying with it an advance of 1s. per week. The men's Union state that in eleven towns chosen by Mr. Hamilton, the Manager, for the purpose of comparison, the average rate of pay is 6·24d. per hour, as against 6d. per hour in Leeds. The matter has been referred back to the Tramways Committee.

LIVERPOOL: *Tramwaymen's Pensions.*—The City Council has adopted a scheme for providing pensions for the tramway employees. Each employee will contribute 2d. per week, and the Corporation will contribute a similar amount.

LONDON: *London County Council: G.B. Surface Contact System.*—A successful trial trip has been made over the line between Aldgate and Bow Bridge, which has been constructed upon the G.B. surface contact system. It is not expected that the full service of cars will be available for about a month.

New Chairman of the Highways Committee.—The Highways Committee of the London County Council have elected Mr. Whitaker Thompson (Vice-Chairman of the Council) as Chairman of the Highways Committee for the coming year. Mr. A. Shirley Benn has been elected Vice-Chairman, and will also represent the Highways Committee on the General Purposes Committee.

Tramways.—On the report of the Law and Parliamentary Committee, Sir John Benn asked whether the committee were aware that in consequence of the arrangement arrived at between Paddington Borough Council and the Metropolitan Electric Tramways, Ltd., unless prompt action was taken the whole cost of the improvements, consequent on the extension of the L.C.C. tramway to Edgware Road, would fall on the County of London, and that by this arrangement Paddington would escape that proportion which other boroughs had paid in like cases. Mr. Cassel, Chairman of the Committee, explained that there was an arrangement between the promoters of the Bill and the County Council, by which at any time up to the end of committee stage in the Second House the Bill should be withdrawn unless the Council approved of certain points. Difficult negotiations were still in progress, and the results would be laid before the Council as soon as possible. Reference to this matter is also made in the "Local Note" under Paddington, below. The Highways Committee reported that the Board of Trade has approved the adoption of the overhead system on the tramways from Hammersmith Broadway to Uxbridge Road.

Camberwell: Underground Telegraph Wires.—The Borough Council has granted the Postmaster-General's request for consent to the placing of underground telegraph lines along 24 thoroughfares in Peckham, subject to the roadways and footways being made good at the expense of the Post Office authorities.

Fulham: Reserve Fund.—The Borough Council having received a report that at the present time there is a sum of, approximately, £2,016 standing to the credit of the Electric Light Machinery Maintenance and Reserve Fund, with reference to which the Finance Committee has been in consultation with the Electricity and Lighting Committee, has decided that the fund be placed to a separate account on deposit at the bank, such reserve account to be duly credited each quarter with the amount of interest it earns.

Greenwich: Tramways.—The L.C.C. is to be asked to construct a double line of tramway from the present terminus to Church Lane, Charlton, or to Charlton Lane. It is proposed by a joint committee of Greenwich Council that that authority contribute one-third of the cost of the road widenings.

Hackney: Electricity Accounts.—The report of the Finance and Electric Lighting Committee for the year ended March 31st, 1907, the fifth complete year of working, show that at that date the equivalent of 151,222 8 c.p. lamps were connected to the mains, including 372 motors, with an aggregate of 1,670 h.p. The total number of units sold was 3,504,336, and the average price received 2·02d. per unit. For public lighting the average price received per unit was 1·31d.; for private lighting 3·11d.; for power 1·07d.; and for destructor power 1d. The total number of units generated was 3,953,453, the difference being accounted for by works lighting and power, 190,665, battery 96,300, and distribution 162,152. The works costs amounted to 0·50d. per unit, and the total cost of generation, distribution, and management was 0·73d. per unit, a reduction of 0·11d. per unit on the result for the previous year. With these costs, Hackney, for the fifth year in succession, secures the record for the lowest costs of generation and distribution of electricity in the metropolitan area. The report gives the following comparisons of total works and management costs per unit sold:—Hackney, number of units sold, 3,504,336; total works and management costs per unit sold, 0·73d. Poplar: Number of units sold, 4,208,302; total works and management costs per unit sold, 0·92d. Stepney: Number of units sold, 4,751,182; total works and management costs per unit sold, 0·98d. Bermondsey: Number of units sold, 1,906,489; total works and management costs per unit sold, 0·99d. Hammersmith: Number of units sold, 4,220,736; total works and management costs per unit sold, 1·07d. Fulham: Number of units sold, 2,214,747; total works and management costs per unit sold, 1·26d. St. Pancras: Number of units sold, 7,276,214; total works and management costs per unit sold, 1·37d. Battersea: Number of units sold, 2,159,873; total works and management costs per unit sold, 1·45d. Shoreditch: Number of units sold, 4,218,574; total works and management costs per unit sold, 1·44d. Islington: Number of units sold, 3,829,650; total works and management costs per unit sold, 1·63d. Hampstead: Number of units sold, 4,303,765; total works and management costs per unit sold, 1·77d. Southwark: Number of units sold, 1,003,855; total

Digitized by Google

works and management costs per unit sold, 1·81d. The financial results of the year's working shows that the total revenue was £31,417 6s. 10d., and working expenditure (including expenses in connection with public lamps), £12,124 10s. 7d. The gross profit for the year, plus interest, was £19,630 19s. Principal and interest absorbed £16,744 18s. 1d., and the balance of £2,886 0s. 11d. has been transferred to the reserve fund. The capital expenditure of the undertaking is £292,078 9s. 3d. The reserve fund now stands at £12,946 4s. 1d.

Marylebone: Expenditure on Electricity Works.—At Tuesday's London County Council meeting, the Finance Committee reported that they had received an application from the St. Marylebone Borough Council for the advance of £9,172 for the undermentioned purposes in connection with the Borough Council's electric lighting undertaking:—(i.) Mains (£5,033); (ii.) Machinery, viz., additional bonus on efficiency of four turbo-dynamos (£1,529), circulating water pump and motor (£845), sub-station switchboards, &c. (£1,480); and (iii.) Telephone equipment (£287). The loan was sanctioned, repayable as follows:—Mains, &c., 30 years; machinery, 20 years; and telephone equipment, 10 years. In addition to this application, the Borough Council has applied for a sum of £44,002, in connection with its electric lighting undertaking, which, added to the sums already sanctioned, will bring the total amount of loans in respect of the undertaking up to £2,043,000. When the last application from the Borough Council for a loan in connection with the undertaking was under consideration, the Finance Committee informed them that, in view of the very large sum which had been expended upon the undertaking, they would feel great difficulty in recommending sanction to any further loans, and that only loans for such additional expenditure as was absolutely necessary would be considered. They have therefore reminded the Borough Council of this communication, and have been told in reply that the present applications relate chiefly to expenditure in connection with the change of pressure and system of supply, and to the balance of the cost of erecting the generating station. With regard to the change of pressure, the Borough Council points out that it was impossible in the early stages to estimate closely the probable cost, and that the work had to be carried through in a very limited time, and involved larger expenditure than was thought would probably have been the case, owing to the stringent regulations laid down by the Board of Trade and the Council. The Borough Council adds that the applications cover the expenditure to date, and that it is not contemplated that any additional outlay on generating plant will be necessary in the normal development of the undertaking for some years to come. The Finance Committee are, however, deferring their report upon the application for the larger amount.

Paddington: Tramways.—The Borough Council has agreed not to oppose the Metropolitan Electric Tramways Company's Bill for an extension of their tramways along the Harrow Road from Lock Bridge to Edgware Road, the company having agreed to carry out, at its own expense, all the necessary street widenings, and to contribute £4,500 towards some street improvements now in the course of progress.

Shoreditch: Expenditure on New Connections.—At Tuesday's meeting of the London County Council, the loan of £7,150 was sanctioned for expenditure from October, 1905, to June, 1907. This has been necessitated by the demands of consumers. 285 additional premises have been connected during the period, whilst mains have been laid over a route length of about 8½ miles. The items and periods of loan are as follows:—Mains, £4,365, 30 years; Meters, £706, 10 years; and house services, £2,079, 12 years. The Finance Committee of the London County Council have, however, informed the Borough Council that it is not desirable that applications of this character should be so long deferred.

Westminster: Underground Telephone Wires.—The Works Committee recommend that a protest be made against the London County Council exercising jurisdiction in connection with the laying of underground telephone wires by the National Telephone Co. in any street in the City, except as may be necessary for the protection of property vested in them, or imposing upon the company any conditions with reference to matters which are within the jurisdiction of the City Council as road authority. It is proposed to forward a communication to the L.C.C. accordingly, and copies to the Postmaster-General, the National Telephone Co., the Corporation of London, and the Metropolitan Borough Councils, with a request to the last-mentioned to address a similar communication to the County Council in the event of their concurring with the views of the City Council. The Works Committee point out that the power given to the County Council by the Telegraph Act, 1892, which, however, only applies to the works of a licensee under the Telegraph Acts, *e.g.*, the National Telephone Co. does not override the power of the road authority, *i.e.*, in London, the respective City, and Borough Councils, but is supplemental to it.

MANCHESTER: *Tramcar Cleaners' Hours.*—The Municipal Employees' Association at Manchester has made an application for an advance of wages for the cleaners and brakesmen. Mr. J. M. McElroy, the General Manager, has replied that the Committee, having carefully considered the application, is unable to comply. The work of cleaning and examining the cars is now done at night, and in order to meet the wishes of the men expressed by a deputation recently, instructions have been given for arranging the work so that each man shall have one night per week off.

OXFORD: *Tramway Position.*—It is stated that an agreement has been arrived at between the Oxford Tramways Co., which owns the existing horse tramways, and the National Electric Construction Co., which has Parliamentary powers to acquire these and to reconstruct them upon the surface-contact system, whereby the present arbitration proceedings shall be abandoned and a new company formed. This new company will receive the Parliamentary concession, and also the plant and property of the existing company. The arrangements, of course, have to receive the sanction of the shareholders of the existing company, and also of the Corporation, as the arbitration proceedings are nominally between these two.

PENZANCE: *Electric Lighting.*—It has been decided to allow the Penzance Electric Lighting Co. until October 31st to give them an opportunity to satisfy the Council that they are in a position to proceed with their Electric Lighting Order. This decision has been come to in consequence of a request by the promoters of the company that the Council shall take no action at present to secure the revocation of the Order of 1904.

PERTH: *Electricity Charges.*—The Town Council has notified the North British Railway Co. and the Highland Railway Co. of their intention to increase the charge for electricity to 2¾d. per unit. The two companies in question have accepted this increase on the distinct understanding that the Council will reconsider the matter when fixing the rates for next year with a view to having them reduced.

SCUNTHORPE: *Provisional Order Revocation.*—The Electric Lighting Order granted to the Urban District Council in 1903 has been revoked by the Board of Trade.

SWINDON: *Tramway Accident Rate.*—The current year's rate at Swindon includes one penny in the pound as a final payment of the rate of 2s. 7d., which was levied in consequence of the heavy claims arising out of the accident on the tramway system two years ago.

YARMOUTH: *Street Lighting.*—Fifty-four incandescent gas lamps are to be converted to electric lighting.

YEOVIL: *Electric Lighting Order.*—The Board of Trade has been informed that the Council does not consider it advisable to take any further steps in regard to putting into force the electric Lighting Order granted in 1903.

YORK: *Tramways.*—A communication has been sent to the Corporation by the Yorkshire Architectural and York Archæological Society protesting against the threatened encroachment of the City ramparts in connection with the electric tramways recently sanctioned by the Light Railway Commissioners. The communication states that the defensive earthwork surrounding the City of York is one of the very few in England that has not been entirely obliterated, and the preservation of it is highly desirable.

TENDERS INVITED AND PROSPECTIVE BUSINESS

ARGENTINE.—The workshops of Tafa Viejo, on the Central Northern Railway (National) are to be electrically equipped, and tenders will shortly be invited.

AYR.—Mr. R. Marshall, the Borough Electrical Engineer, recommends the installation of a 500 kw. alternator and other additions. Application is to be made for sanction to borrow £30,000 to meet extensions during the next eight years.

BECKENHAM.—It is proposed to install a battery at the generating station.

BRAY.—The Urban District Council invites tenders for electrical stores during the year ending April 1st, 1909, including cable, carbons, switches, incandescent lamps, &c. Tenders to the Clerk by April 7th.

BRISTOL.—The Electricity Committee invite tenders for a twelve months' supply of arc lamp carbons, and joint and junction boxes. (See an advertisement this week.)

BURSLEM.—At the last meeting of the Council, the Electric Lighting Committee reported that Mr. H. R. Hooper, the Local Government Board inspector, had recently visited the works at Burslem, and had remarked to the Engineer that having regard to the probability of the scheme for the federation of the Potteries being carried through, it was inadvisable to carry out any extensions at Burslem except those absolutely necessary to meet immediate requirements. The committee, however, adhere to their resolution to apply to the Local Government Board for sanction to borrow £12,000 for the electrical undertaking. This recommendation has been confirmed by the Council.

CHESHIRE LINES COMMITTEE.—Tenders are invited for

Digitized by Google

the purchase of a second-hand boiler, steam engine, &c. Full particulars from the Engineer at Central Station, Liverpool, and tenders by April 7th. (See an advertisement this week.)

CHESTER.—The installation of a refuse destructor at the electricity works has been decided upon.

DEWSBURY.—The Electricity Committee invite tenders for surface condenser and cooling tower. Full particulars from the electricity works (fee £1 1s., returnable), and tenders to the Chairman of the Electricity Committee by March 30th.

DUBLIN.—The North Dublin Union Guardians are considering the lighting of the union with electricity.

EDINBURGH.—Tenders are invited for the supply of the following material for the Electricity Supply Department for the year from May 16th, 1908:—1. Bitumen. 2. Arc lamp carbons. 3. Arc lamp globes. 4. Cast-iron pipes and pavement boxes. 5. House service fuse-boxes. 6. Electricity meters. Particulars from the Engineer's office, Dewar Place, Edinburgh (fee, 10s. for each specification, returnable), and tenders to the Town Clerk by March 30th. (See an advertisement this week.)

FROME.—Mr. H. R. Hooper held a Local Government Board inquiry last week into an application by the Urban District Council for sanction to borrow £11,100 for the purpose of the electric lighting undertaking. The inquiry was adjourned until March 31st.

HALIFAX.—The Tramways Committee recommend that motors and material be purchased at an estimated cost of £6,000. This includes £4,000 for fifty 35 h.p. motors to replace existing 25 h.p. motors, and £1,100 for controllers for same.

HUDDERSFIELD.—Tenders are invited for the supply of single-phase alternating-current meters during the ensuing twelve months. Tenders to the Town Clerk by March 25th.

BLACKBURN.—Tenders are invited for the new Y.M.C.A. Hall in Limbrick, Blackburn, which will be lighted by electricity. The architect is Mr. T. J. Parkinson, of Richmond Terrace, Blackburn.

LEEDS.—The Electric Lighting Department invite tenders for the supply of steam coal and various supplies, including rubber-covered cables, main boxes, jointing and insulating material, electric lamp fittings, and sundries. Particulars from the Manager, and tenders to the Town Clerk by March 31st.

LIVERPOOL.—The Tramways, Electric Power and Lighting Committee recommend that application be made to the Local Government Board to borrow £3,000 for the erection of additional buildings at the Northend sub-station.

LONDON: *Bermondsey.*—The Electrical Engineer has submitted estimates for extensions as follows:—750 kw. generating set, £5,810; marine boiler, 14,000 lb. evaporation, £1,900; condenser, 25,000 lb., £3,460; total, £11,170. In a report made, the Electricity Committee recommend that the work should be put in hand with the least possible delay, so that the proposed extended plant may be ready to meet the increased demand which may confidently be looked for in the coming winter.

Hampstead.—A new sub-station is to be erected at an estimated cost of £380.

Marylebone.—Sanction has been granted for a loan of £9,172 in connection with the Borough Council's electricity undertaking, and application has been made with regard to an additional £44,002. Further particulars will be found in our "Local Notes" pages.

Shoreditch.—Haggerston Baths are to be re-wired at an estimated cost of £75 15s. 6d. In the working-class dwellings, 106 prepayment electricity meters are to be installed, at an estimated cost of £225. A commutator grinder is to be obtained for the generating station, at an estimated cost of £65.

ROTHERHAM.—The Engineer, Mr. E. Cross, recommends an application to the Local Government Board for a loan of £3,500 for the addition of a turbo-alternator with condensing plant, switchboard, &c., to the electricity works. This recommendation has been confirmed by the Corporation.

WOLVERHAMPTON.—Double-deck tramcars are to be purchased at an estimated cost of £2,000.

TENDERS RECEIVED AND ACCEPTED

AUSTRALIA: *Victoria.*—The tender of Mr. R. B. Hungerford, 163 Pitt Street, Sydney, has been accepted by the Victorian Postmaster-General's Department for the supply and delivery, at Melbourne, of five sections of a telephone switchboard for incoming junction lines for the Central Telephone Exchange, Melbourne, at £2,989.

In connection with the erection of a central telephone exchange in Latrobe Street, Melbourne, the tender of Messrs. Swanson Bros., at £18,499, has been accepted.

BARNES.—The Urban District Council has accepted the tender of Babcock & Willcox, Ltd., at £855, for a locomotive crane.

BRIGHTON.—Tenders have been received for carbon filament incandescent lamps for street lighting, and the Engineer reports that the best all-round lamp for life and efficiency is that submitted by the Sun Electrical Co., who quote 6¾d. per lamp, and the second best that of the British Thomson-Houston Co., who quote 6d. per lamp, a reduction of 1d. and 1¾d. respectively on the amount paid under the present contract. The Engineer points out, however, that these reductions in price have been made at the expense of the efficiency of the lamps, for whereas the running contract is for lamps consuming 3½ watts per candle, the present offers are on the basis of 4½ watts. This would mean an additional £468 per annum in the cost for electricity. Under the circumstances, he strongly recommends the Council to reject the whole of the tenders received, and to adopt the new 16 c.p. "Tantalum" lamp which has just been put upon the market. By this means the candle-power at present given, he estimates, could be exactly doubled for the same consumption of current at a net increased cost of £138 per annum. If this suggestion is adopted, the Engineer states that the cost of the present street lighting, with double the candle-power, could be effected for £2 18s. per post per annum, compared with £3 0s. 6d. for incandescent gas. The report was adopted at the last meeting of the Corporation.

DARTFORD.—Since the termination of the contract with the A.B.P. Accumulator Co., the Electrical Power Storage Co. has been entrusted with carrying out the renewal of the cells of the lighting battery at about 40 per annum, the cost being £86 per annum. At this rate the renewal of the battery will be completed in five years' time, but the Electricity Committee regard this method as disadvantageous, and recommends that a contract be entered into with the Electrical Power Storage Co., to renew the whole of the cells at once at £392, the payment to be spread over five years.

DERBY.—The tender of the British Thomson-Houston Co. for a Tirrill regulator at £82 10s. has been accepted. The following tenders have also been received:—Cast iron piping, Messrs. Cinkins & Knighton, £133 8s.; steel piping, Messrs. Aiton & Co., £115. The tender of Mr. W. Walkidine for the construction of car sheds at Nottingham Road at £4.998 16s. has been accepted. Ten tenders were received, the accepted one being the lowest. The proposed shed will accommodate 20 cars.

GREYSTONES (IRELAND).—The Rathdown Rural District Council has requested the Wicklow County Council to give the necessary permission to Messrs. Coates & Sons for carrying out the proposed scheme for lighting Greystones by electricity.

LONDON: *London County Council.*—The tender of Messrs. John Smith (Keighley), Ltd., has been accepted for the supply of a 10-ton overhead travelling crane for the Hammersmith temporary tramways sub-station at a price of £159 10s. Other tenders received were from Carrick & Ritchie (£201) and Thos. Larmuth & Co. (£210). The following tenders have been received for points and crossings for the junctions required upon the reconstruction of the Brixton Road tramways on the overhead trolley system:—Lorain Steel Co. (U.S.A.), £833 10s.; Hadfield Steel Foundry Co., £808 12s. 6d.; Edgar Allen & Co., £888 10s. The Chief Engineer's estimate was £810. The Lorain Steel Co.'s tender was on the basis that the Council should supply to the company, free of charge, wrought rails for use in manufacturing the crossings required, instead of these rails being made of cast-steel in the usual manner. On making allowance for this the Lorain Co.'s tender would no longer be the lowest, and therefore the Hadfield Steel Foundry Co.'s tender has been accepted.

The Asylums Committee has accepted the following tenders for the annual supply of electric lighting sundries:—British Thomson-Houston Co., Ltd., £110 14s. 7d.; General Electric Co., Ltd., £2; Baxter and Caunter, £22 16s. 8d., £43 17s. 8d., £44 18s., and £11 13s.; Pryke and Palmer, £18 10s. 10d. and £21 8s. 11d.; H. S. Timpson, £66 0s. 7d.; India-rubber Gutta-percha and Telegraph Works Co., Ltd., £3 13s.

Bermondsey.—The Borough Council has accepted the tender of the Brush Electrical Engineering Co. at £23 7s., for spare parts for a 500-kw. set.

Camberwell.—The Borough Council has accepted the following tenders for annual supplies:—Electric lamps, plain. Britannia Electric Lamp Works (1905), Ltd., 100 volts, 8 and 16 c.p., 5s. per dozen; 32 c.p., 5s. 6d.; 200 volts, 8 and 16 c.p., 5s. 6d. per dozen; 32 c.p., 6s. per dozen; frosted, 100 volts, 8 and 16 c.p., 5s. 6d. per dozen; 32 c.p., 6s.; 200 volts, 8 and 16 c.p., 6s.; 32 c.p., 6s. 6d. "Osram" electric lamps, 100 volts. Geipel and Lange, 30 c.p., 36s.; 50 c.p., 38s. 3d. Maintenance of private telephones and electric bells, Private Wire and Telephone Installation Co., Ltd., Town Hall, £4 4s. per annum; Grove Vale depôt, £3 3s.

Hammersmith.—The Borough Council have accepted the following tenders for annual supplies:—Arc lamp globes and lamp shades, H. G. Mayer and Co., £20 17s., less 2½ per cent. discount; electrical accessories, Veritys, Ltd., £16 11s. 2d., less 2½ per cent.; electrical insulating goods, for whole of items. General Electric Co., £15 16s. 11d., less 2½ per cent.; for Para

Digitized by Google

rubber strip, tape, and solution only, Siemens Bros. & Co., £12 19s., less 2½ per cent.

St. Pancras.—The Borough Council has accepted the tender of Messrs. Brentnall and Cleland to supply 500 tons of best hand-picked "Desford" steam coal at 15s. 8d. per ton, delivered to either electricity station, subject to a condition that this supply be discontinued so soon as Messrs. Barber-Walker's collieries re-open after the strike, and the Council can be supplied therefrom under their contract.

LOWESTOFT.—The tender of Messrs. W. T. Henley's Telegraph Works Co., Ltd., for house cut-outs at 4s. per pair, and 10s. 6d., 6s., and 6s. 9d. per set has been accepted. An offer by the Underfeed Stoker Co., Ltd., to supply mechanical stokers to two of the boilers of the power-house, at £350, the Corporation finding the motor, has also been accepted. Payment is to be spread over two years by eight quarterly payments.

SHEFFIELD.—The following firms have been successful in obtaining the contracts for the supply of electrical and engineering goods for the twelve months ending March 25th, 1909, to the Corporation Cleansing Department and Telegraph Works:—Messrs. Dewhurst's Engineering Co., the India-Rubber and Gutta-Percha Co., Taskers' Engineering Co., Messrs. Taskers Sons & Co., Mr. J. Robinson, Messrs. T. A. Ashton, Ltd., Messrs. S. Peace & Son, Messrs. Chas. Mackintosh & Co., the Sheffield Corporation Electrical Supply Department, and Mr. W. Bakewell.

WEST HAM.—The Education Committee has placed an order with the Borough Electrical Engineer for the supply of "Osram" lamps at the following rates:—30-c.p. lamps, 4s.; 50-c.p. lamps, 4s. 3d.

WOLVERHAMPTON.—The Empire Roller Bearings Co. have received an order for fitting further cars for the Corporation with roller-bearing axleboxes.

YARMOUTH.—The tender of Messrs. Bessey & Palmer for 500 tons of coal at 15s. 11d. per ton, for the Electricity Department, has been accepted.

APPOINTMENTS AND PERSONAL NOTES

By a clerical error the name of Mr. H. F. Forbes Mackay, late of the Great Western Railway Electrical Department, who has been appointed electrical engineer to the Municipality of Sydney, was given on pages 419 and 416 as H. F. Forbes.

The Stepney Borough Council has increased the salary of Mr. W. C. P. Tapper, the Electrical Engineer and Manager, from £650 per annum to a maximum of £750 per annum, the re-adjustment taking effect from July 24th last, on which date instructions were given him to proceed with the preparation of the Blyth's Wharf scheme. The salary of Mr. A. J. Squire, the chief clerk in the electricity department, has been increased from £200 to £210 per year, with further annual increments of £10 until a maximum of £250 per year is reached.

Mr. J. R. Woodruffe Gardam, late manager and engineer to the Empire Electric Light Co., Sydney, Australia, has been appointed representative of Messrs. Noyes Bros., at Perth, West Australia.

Mr. F. Hope Jones, M.I.E.E., has been awarded the bronze medal of the Royal Humane Society for his attempts to rescue a skater who had fallen through the ice at the Welsh Harp last January. Mr. Hope Jones dived no less than five times, but failed to effect a rescue.

At the Halifax Corporation tramway shed on Friday, Mr. F. Spencer, the retiring tramway manager, was presented with a Doulton dinner service, consisting of 73 pieces, by the tramway staff.

MISCELLANEOUS CITY NOTES

ELECTRICAL DEVELOPMENT CO., ONTARIO.—It is stated that negotiations are complete for transferring the control of this company to the Toronto Railway Co. The proposal is that the Toronto Railway Co. will guarantee bonds which will pay off the floating debt of the Electrical Development Co., and provide working capital. Ordinary stock of the Electrical Development Co. will be transferred to the Toronto Railway Co., sufficient to ensure it the control.

GENERAL ELECTRIC CO.—A notice in Tuesday's *London Gazette*, summoning the shareholders of the General Electric Co., Ltd., to a meeting to receive the report of the liquidator as to the winding up of the company, need not cause any alarm to the friends and clients of the G.E.C. It relates merely to the old parent company, which was a private limited company, registered in 1889. In 1900 the company was reconstructed as a public company, under the title of the "General Electric Co. (1900), Ltd.," £500,000 being paid to the old company as purchase money. Four years ago the word "1900" was again dropped from the name of the company. The notice in question represents the final step in the liquidation of the old company, commenced at the end of 1900. The present General Electric Co. is as flourishing as ever.

LANARKSHIRE TRAMWAYS CO.—An extraordinary general meeting was held on Wednesday to sanction additional capital required for the construction of the remaining extensions authorised by the Order of 1903.

LONDON STREET TRAMWAYS.—The report for the year 1907 shows a net profit of £4,129. The directors recommend a dividend of 2s. 6d. per share, which will absorb £3,875, leaving £254 to be carried forward.

NEWCASTLE ELECTRIC SUPPLY CO.—Subscriptions have been invited during the week for an issue of £50,000 preference shares and £50,000 ordinary shares of £5 each. Lloyd's Bank, in conjunction with others, have purchased the whole issue at a premium, and offer it for sale at £5 for each preference share, and £6 for each ordinary share. The prospectus states that during the last ten years the horse-power connected to the company's system has increased from 2,200 to 92,764, whilst at the present time a further 27,000 h.p. is awaiting connection. During January and February this year, the number of units sold shows an increase of 24 per cent. over those of the corresponding period of 1907. The prospectus further states that the original system laid down in 1890 has been entirely replaced by a modern high-tension system out of monies set aside for reserve and depreciation. As stated in our last issue, the new capital will be utilised in equipping an extra power station at Dunston-on-Tyne, and in redeeming the third mortgage debentures.

ROSARIO ELECTRIC CO.—A dividend of 3s. per share, less tax, has been declared upon the ordinary shares.

SOUTH LONDON ELECTRIC SUPPLY CORPORATION.—In the Chancery Division, on Saturday, a petition was heard for the reduction of the capital of this company from £65,000 in £5 shares to £65,000 in £4 shares. This decision has been rendered necessary in consequence of the results of the legal proceedings between the Lambeth Borough Council and the company regarding the refuse destructor, which has been dismantled. The application was granted.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO.—The register of debenture stockholders will be closed from 18th to 31st instant, for preparation of warrants for interest at the rate of 4½ per cent. per annum for the half-year to April 1st, 1908.

TELEPHONE COMPANY OF EGYPT.—Subscriptions have been invited for 20,000 4½ per cent. debenture stock, ranking *pari passu* with the stock now quoted on the Stock Exchange. The present issue is offered at par, and carries a full half-year's interest on July 1st.

WESTERN TELEGRAPH CO.—A second quarterly interim dividend of three shillings per share has been declared free of income tax for the year ending June 30th, 1908, being at the rate of six per cent. per annum. The transfer books of this company will be closed from March 18th to March 24th, both days inclusive, and the dividend will be payable on March 25th.

Electrical Bills in Parliament, 1908.—The annual report of the Board of Trade upon all the Bills and Provisional Orders for the current Parliamentary Session relating to railways, tramways, electricity, &c., has been issued. There are 19 tramway Bills, involving the construction of 31 miles of new line, the aggregate capital proposed being £525,000 in shares and £749,760 by loans. There are 27 electric lighting Provisional Orders, involving a capital of £259,180, and three tramway Provisional Orders involving a capital of £14,002, nine Bills relating to the supply of electrical energy, the proposed capital of which amounts to £7,600,000. Some particulars are given in the return of all the electrical Bills before Parliament, a full digest of which will be found in ELECTRICAL ENGINEERING, Vol. II., p. 1007.

Telegraph Traffic. During the past week a few more interruptions to the telegraph service have to be recorded. The El Arich route between Peyreuth and Lattagui ceased working from March 11th to 13th. On the 15th instant the cable between Tangier and Cadiz was again restored to working order, while two days later we received information of the interruption of the cable belonging to the Compagnie Française des Cables Télégraphiques, between Cayenne (French Guiana) and Salinas (Brazil). The land line to Ahvaz, in Persia, has at last been restored. Information has also reached us to the effect that telegrams to the Island of Guadeloupe must be forwarded by mail from contiguous islands. We have already notified that the Martinique-Guadeloupe cable is down, and the above information indicates that the cables between Dominica and Guadeloupe, and between Antigua and Guadeloupe, belonging to the West India and Panama Telegraph Co., must also be interrupted. As Guadeloupe is the handing-over centre in the West Indies for the West India and Panama and the French West India telegraph systems, some inconvenience will ensue, as the cable between Mole St. Nicolas and Guantanamo is also down. There being no other known interruption in the West Indies, it is probable that the cable ship *Henry Holmes* is already engaged in the repair of these cables. Communication with Alderney, Channel Islands, has also given out. The Central and South American Telegraph Co. have now stationed the cable steamer, *Relay* (Captain Alex Taylor), 1,200 gross tonnage, in the Atlantic, where she has arrived from Callao, Peru, her former station, to take the place of the cable steamer *Mexican*. Their new boat, the *Guardian*, will now be stationed at Callao. The gross tonnage of the cable ship *Mexican* being only 402, there is no doubt she is now considered too small a vessel to undertake repairs on the New York-Guantanamo-Colon cable.

MISCELLANEOUS BUSINESS NOTES

PRICE OF COPPER.—Messrs. George Smith & Sons, of Philpot Lane, London, E.C., inform us that the price of electrolytic wire bars, net c.i.f. port of arrival, quoted on Tuesday night, was £59 10s. to £60 per ton (last week £59 to £59 10s.).

ARTISTIC FITTINGS.—We are informed that, owing to expiration of lease, Messrs. Strode & Co. are offering for sale a surplus stock of fittings and accessories below cost price at their City showrooms, 67 St. Paul's Churchyard, E.C.

CALENDAR.—A wall calendar (from March, 1908, to March, 1909), upon which is a series of portraits of the principal heads of departments, has been issued by the General Electric Co. It should be of considerable use to all the company's customers.

SIMPLIFIED UNDERGROUND CONDUCTOR CO.—We are informed that the Howard Asphalt Troughing Co., Ltd., have purchased outright the whole of the patents formerly belonging to the Simplified Underground Conductor Co., Ltd. (in liquidation), of 180 Crown Street, Liverpool.

GREAT CENTRAL RAILWAY.—We have received from the Great Central Railway Co. an illustrated booklet, entitled "Strolls in Beechy, Bucks," containing illustrated descriptions of walks in the county of Buckinghamshire. Copies, post free 2½d., may be obtained from Publicity Department, Great Central Railway, 216 Marylebone Road, N.W., or the publisher, Walter Hill, 67-69 Southampton Row, W.C.

LIQUIDATIONS, BANKRUPTCIES, WINDINGS UP, &c.—A meeting of the Electric Power Development Co., Ltd., will be held at 21 Ironmonger Lane, London, E.C., on April 14th, at 12 noon, to receive the liquidator's account of the winding-up.

A supplementary dividend of 2½d. in the £ will be paid on March 25th at the Official Receiver's Offices, 24 Bond Street, Leeds, in the bankruptcy of Albert Dickinson, electrical engineer, Dixon Lane Road, Wortley, Leeds.

The trustee has been released in the bankruptcy of G. & J. S. Robson, trading as Robson, Robson & Co., electrical engineers, at Empire Buildings, Newgate Street, Newcastle-on-Tyne.

DISSOLUTIONS OF PARTNERSHIPS.—H. Cecil Hodges and Harry Snowdon, carrying on business as electrical engineers and manufacturers at Balfour House, Finsbury Pavement, London, have dissolved partnership. Debts due to and owing by the firm will be received and paid by H. Snowdon, at Snowdon's Wharf, Millwall, London, E.

George Arthur Knapton and Robert Ironside Bagnall, trading as electrical engineers as Knapton, Bagnall & Co., at 95 Lansdowne Road, Old Charlton, Kent, have dissolved partnership. G. A. Knapton continues as G. A. Knapton & Co.

The partnership between A. H. Sowerbutts and F. Walker, electrical engineers, 17 High Road, Kilburn, under the title of Sowerbutts & Rogers, has been dissolved.

Notice is given of the retirement of Mr. E. S. Hindley, from Messrs. E. S. Hindley & Sons, engineers and manufacturers of machinery, 11 Queen Victoria Street, London, and at Bourton, Dorset. The business will be carried on as usual by the remaining partners.

ROBERTSON'S SOCIAL AND ATHLETIC CLUB.—A plain and fancy dress dance was held at the electric lamp works, Brook Green, Hammersmith, on Saturday. There was an attendance of about 350.

COMPANIES' MEETINGS AND REPORTS

BRITISH INSULATED & HELSBY CABLES.—The report for the year ended December 31st, 1907, shows that the profit amounts to £135,619, to which has to be added the balance brought forward from last year, £36,713, making a total of £172,332. Deducting directors' and debenture trustees' fees, interest on debenture stock, depreciation, &c., dividend on preference shares to December 31st, 1907, interim dividend on ordinary shares to June 30th, 1907, &c., £113,997, leaves £58,335. The directors recommend a further dividend of 4 per cent. on the ordinary shares, making a total of 8 per cent. for the year ended December 31st, 1907, together with a bonus of 2 per cent., which will absorb £50,000, carrying forward £28,335. The volume of trade during the past year, especially in heavy cable work, has not been so great, owing to the high price of copper in the earlier part of the year, and to the financial stringency later on, and the profits have thereby been adversely affected. It is, however, satisfactory to be able to say that the volume of business done so far this year and orders in hand at present compare very favourably with the corresponding period of last year. A sum of £10,000 has been transferred to reserve account, and a further £5,000 to debenture stock redemption account, in addition to £22,000 depreciation of buildings, plant, and machinery. The meeting is on Monday.

DEVONPORT AND DISTRICT TRAMWAYS.—The half-yearly meeting was held in London on Wednesday last week, Mr. W. G. Bond presiding. The accounts show an available balance of £2,157, and it is proposed to transfer £1,000 to permanent way renewals fund, £1,000 to capital redemption fund, and to carry forward the remainder. There has been a decrease in the receipts of £346, and an increase in the expenditure of £175, making a net reduction for the half-year of £521, compared with the previous half-year. Permanent way repairs and maintenance are largely the cause of the increased expenditure. This, said the Chairman, was a cause of expense over which the company had no control, and their efforts at opening up new sources of revenue and to stimulate existing sources had not met with any great success. A parcel service had been inaugurated, and the issue of workmen's tickets had been instituted, but the latter had been withdrawn. The directors were of an opinion that it would be very good business both for the company and for the Plymouth Corporation if they ran over each other's lines, but so far they had been unable to induce the Corporation to agree. In view of the present position, the directors had placed the situation of the company frankly before the Devonport Corporation, from whom they rent nearly 50 per cent. of the lines they work upon very onerous terms. In fact, said the Chairman, it was practically these onerous terms which had stood between the ordinary shareholders and moderate dividends. In most prosperous days, they had never paid more than 4 per cent., but since they had been working the Devonport extension no dividends had been paid at all. The letter which had been addressed to the Corporation suggested that the Corporation should re-arrange the terms so far as interest and sinking fund paid by the company were concerned, and also reduce the price charged for electrical energy from 3d. to 1·4d. to 3d. to 1·2d., the lower price to be reduced every subsequent year by one-tenth of a penny until ·8d. was reached. The Corporation is also asked not to oppose the running of Devonport cars into Plymouth, nor *vice versâ*. Failing the acceptance of these terms, the directors intimate their willingness to negotiate for the sale of the company's undertaking to the Corporation.

CHELSEA ELECTRICITY SUPPLY.—At the annual meeting held on Wednesday last week, Sir I. Courtney presiding, the report and accounts given in our issue for February 27th were adopted. In referring to the increase in the expenditure of £2,158, the Chairman stated that this chiefly related to coal, which accounted for £1,304, whilst increased rates accounted for a further £695. The total now paid in rates, he said, was £5,843, or more than 45 per cent. of the amount distributed in dividends, and equal to two-fifths of a penny per unit sold. The gross receipts had increased by £1,285, and they had been able to pay the same dividend as last year, in addition to placing a substantial amount to depreciation and writing off amounts in respect of two items. The works costs per unit sold were almost the same as last year. Very little capital expenditure had been incurred during the year, extensions having been made to the distributing mains only where necessary to furnish a supply to new consumers. Referring to the use of metallic filament lamps, the Chairman expressed the same views as those of other chairmen of electric lighting companies, namely, that the supply industry would benefit from their adoption eventually. At a subsequent special meeting, the promotion of the London Electricity Supply (Joint Committee) Bill was confirmed.

CITY OF LONDON ELECTRIC LIGHTING.—The report for the year ended December 31st, 1907, states that the total capital expenditure up to that date was £2,181,038. The capital expenditure during the year was £87,069, and £176,436 has been written off at various times, including £38,958 during 1907, so that the net addition to capital account for the year was £39,710, and the net total as at December 31st is £2,051,960. The total reserves now stand at £300,601. The total revenue for the year, including £1,719 for interest on investments and discounts, was £280,861, from which must be deducted the following items:—Expenses of generation and distribution, £66,561; repairs and maintenance of buildings, machinery plant, mains, and other works, £10,265, and rent, rates, taxes, management expenses, and special charges, £45,285, leaving £158,750, to which must be added the balance brought forward from 1906, £20,621; making a total available revenue of £179,371. Of this sum the following amounts have been distributed or provided for:—Interest on loan from bankers, consumers' deposits, &c., £4,378; interest on first and second debenture stock for year ended December 31st, 1907, £31,825; interest transferred to debenture stock premium redemption fund, £1,511; staff superannuation fund, £336; Parliamentary expenses, £1,093; stores: values written down, £301; experimental street arc lighting, £1,115; provision for doubtful debts, £1,600; amount applied in reduction of certain items of the capital account, £8,400; transfer to reserve account, £45,000; transfer for leasehold redemption, £500; leaving £85,513 for dividends on preference and ordinary shares, and for "carry forward" to 1908. The directors now recommend that the following dividends for the year ended December 31st, 1907, be declared, subject to the deduction of income tax, to members registered in the books of the company at the closing of the transfer books on March 4th, 1908. Preference shares Nos. 1 to 40,000.—12s. per share, being a distribution for the year at the full rate of 6 per cent. Of this sum 6s. per share was paid on account on July 17th last, leaving a balance of 6s.

Digitized by Google

per share for present distribution. Ordinary shares Nos. 40,001 to 110,595.—12s. per share, being a distribution at the rate of 6 per cent. for the year. Of this sum 5s. per share was paid on account on July 17th last, leaving a balance of 7s. per share for present distribution. The dividends to be distributed as above amount to £34,873, which, with the dividends already distributed, brings the total dividends for the year up to £65,039, leaving £20,474 to be carried forward to 1908. The report gives some comparative tables setting out the position of the company at the ends of various years. The gross revenue has increased by £18,092 over that in 1906, and there has been a corresponding increase of £12,775 in the net revenue. The average price per unit obtained for private supply was 2·63d., as against 2·64d. in 1906, and consumers show an increase of 226, and the connections the equivalent of 110,160 8-c.p. lamps, or 3,672 kw. On February 19th, 1908, there were 1,041,293 8-c.p. lamps (equivalent to 34,710 kilowatts) applied for, out of which 1,022,695 were connected, and the customers numbered 12,581. The total units generated during the year were 26,393,590, of which 23,684,575 were sold, 744,810 were used on works, and 1,964,205 were expended in distribution, &c. The maximum supply demanded was 17,908, so that the load factor works out at 15·1 per cent. The total units sold during 1907 show an increase of 2,020,472 over the quantity sold during 1906. Power and heating supplies continue to show a steady increase, the total units sold during the year for power purposes being 5,169,640, and for heating, 914,415. These are together equal to 27·19 per cent. of the total units sold for private supply. In July last the Corporation of London acceded to the company's request to be allowed, in certain thoroughfares of the City, to alter some of the standards and replace the arc lamps previously in use, by arc lamps of a modern type. These new lamps have been in satisfactory operation during the past winter, and the directors hope that the demonstration will have the effect of proving the superiority of electricity for street lighting. The expenditure incurred by the company up to December 31st, 1907, amounting to £1,114 11s. 3d. has been charged against revenue. The directors have thought it advisable to take an interest in a small limited liability company formed by a certain number of the London electric supply companies for the purpose of promoting a Joint Bill in the present Session of Parliament. The expenses incurred in connection with Parliamentary matters during the year 1907, amounting to £1,033, have been also charged against revenue. The meeting was held yesterday.

COUNTY OF LONDON ELECTRIC SUPPLY.—The report for the year ended December 31st, 1907, states that the capital expended during the past year on account of the company's London districts amounted to £57,670, and the sum of £19,679 has been deducted in respect of machinery displaced. The net total expenditure in respect of those districts up to December 31st last amounted to £1,571,777. The total revenue for the year was £109,089, out of which £39,908 was absorbed by interest on debentures, £11,400 was paid as dividend on preference shares, £7,600 as interim dividend, at the rate of 4 per cent., and £23,000 was carried to reserve for depreciation, repairs, renewals, &c., leaving £27,181 for further distribution. The directors now recommend :—(*a*) That payment of the interim dividend on 40,000 six per cent. preference shares for the half-year ended June 30th, 1907, less income tax, be confirmed. (*b*) That payment of the interim dividend on 40,000 ordinary shares, at the rate of four per cent. per annum, for the half-year ended June 30th, 1907, less income tax, be confirmed. The Directors also recommend :—(*c*) That a further dividend on 40,000 six per cent. fully-paid preference shares for the half-year ended December 31st, 1907, less income tax, be declared; and (*d*) That a further dividend on 40,000 ordinary shares for the half-year ended December 31st, 1907, at the rate of six per cent. per annum, less income tax, be declared, and that the said dividends be paid to all proprietors registered on March 6th, 1908. The above-mentioned payments (*c*) and (*d*) will absorb £22,800, and leave a balance of £4,381 4s. 9d. to be carried forward. The profits derived from the company's London stations for 1907 amounted to £118,200 17s. 7d., against £105,300 3s. 8d. for 1906. The total applications received at December 31st last amounted to the equivalent of 1,001,171 50-watt lamps (30,035 kilowatts), being an increase of 106,040 lamps (3,181 kilowatts) for the year. Included in these figures are motors aggregating 14,851 h.p., being an increase of 2,166 h.p. for 1907. The total units sold were 13,970,179, as against 10,755,424 for the previous year, being an increase of 29·9 per cent. The funds required to meet the capital expenditure incidental to the increasing business of the company have been provided by an issue of six per cent. preference shares at par to the shareholders. The Bournemouth and Poole Electricity Supply Company, Ltd., continues to show satisfactory progress. The directors have recommended a final dividend on the ordinary shares of that company at the rate of 9 per cent. for the six months ended December 31st last, making 7 per cent. for the year. The business of the Coatbridge & Airdrie Electric Supply Company, Ltd., formerly the Scottish House-to-House Electricity Company, Ltd., shows substantial improvement. During the year additional applications for the equivalent of 28,999 30-watt lamps (870 kilowatts) have been received, including 907 h.p. in motors. The Bulk Supply Bill, promoted in 1907 by the London Electric Supply Companies, and referred to in the last report, was withdrawn. A limited liability company has been formed by eight of the London Supply Companies, and a Bill is being promoted by that company in the present session of Parliament. The directors have deemed it well to secure an interest in that company, and an extraordinary general meeting of the shareholders has been convened for the purpose of considering and, if thought fit, approving, the proposed Bill. A supply is now available in Purley and Sanderstead under the company's Croydon Rural Provisional Order. The Royal assent has been obtained to the Provisional Order promoted by the company in the last session of Parliament for the district of the Maldens and Coombe Urban District Council, which adjoins the company's existing areas of supply.

At the meeting on Monday the report and accounts were adopted. Mr. J. P. Braithwaite, the Chairman, who presided, said that, taking the company's capital expenditure during the past seven years, there had been a steady decrease going on, and the company's engineer estimated that this would still further decrease in the future. He had been asked by the shareholders whether the capital expenditure was profitable. In 1903 a capital expenditure of £133,772 gave an increased profit of 8·7 per cent.; in 1904 a capital expenditure of £83,504 gave an increased profit of 23 per cent.; in 1905 a capital expenditure of £82,380 gave an increased profit of 11·7 per cent.; and in 1906 a capital expenditure of £67,813 resulted in an apparently increased profit of 4·3 per cent.; but in this case the bulk of the capital expenditure was made towards the end of the year, and was really not effective until the following year. In 1907 a capital expenditure of £57,670 gave an increased profit of 22·3 per cent. Taking, therefore, the five years altogether, a total capital expenditure of £425,139 gave an increased profit of £56,504, or 13·2 per cent. He thought this would satisfy the shareholders that the directors did not spend capital rashly or recklessly. With regard to the revenue account for 1907, the receipts showed an increase of 12½ per cent., or £19,561, whilst the increase in the works costs amounted to £5,628. There had been increases in one or two other directions over which the directors had no control, such as rates and quinquennial valuation, whilst income tax and wages had increased somewhat. Taking the London stations alone, which were the backbone of their business, the revenue showed an increase of £20,438, or 14 per cent. The five 1,500 kw. Curtis turbines were working exceedingly well, and the lamp connections for the year were an absolute record. The efficiency of distribution showed an improvement of 3 per cent. for last year, and was now 75·9 per cent., an improvement due to the increased sale for power purposes. On December 31st last they had just over one million lamps applied for, but the progress for 1908 was even better. The applications up to date were equivalent to 23,520 thirty watt lamps, against 16,139 last year, an increase of 46 per cent. The average price per unit had gone down from 4·58d. in 1902 to 2·83d. in 1907. The fact that the increase of business had synchronised with the decrease in price, and that still they were making larger profits was very great testimony to the soundness and efficiency of their staff. The Chairman concluded with a reference to the London power question, and said he was not without hope that the President of the Board of Trade would call a conference of all parties concerned, for he was quite sure that if they could once get round a table on a business footing, the matter would soon be settled to their mutual satisfaction.

At an extraordinary general meeting held subsequently, the London Electric Supply (Joint Committee) Bill was approved.

DIRECT SPANISH TELEGRAPH.—The report and accounts for the year ended December 31st, 1907, show, after providing for interest on and redemption of debentures, and crediting the reserve fund with the sum of £3,905, an available balance of £2,793, which enables the directors to recommend the declaration of the dividend of 10 per cent. on the preference shares, and a dividend of 4 per cent., free of income-tax, on the ordinary shares, for the year 1907, amounting to £5,586. Half of this amount was distributed on October 1st, 1907, as an interim dividend in respect of the half-year ended June 30th, 1907. The traffic receipts shown an increase of £302, and the ordinary working expenses a decrease of £142, as compared with the year 1906. During the year 1907 the Bilbao cable has been twice interrupted. On the first occasion the break occurred at about 25 knots from Falmouth, and the necessary repairs were effected by the Eastern Telegraph Company's cable steamer *Britannia*, after an interruption to communication lasting four days. The second break took place at about 19 knots from Arrigunaga, the cable being repaired by the cable steamer *John Pender* after an interruption of nine days. The cost of these repairs, amounting to £3,294, has been charged to revenue. Sir John Denison-Pender, K.C.M.G., is the director retiring by rotation, and offers himself for re-election. The meeting is to-day.

W. T. GLOVER.—The accounts for the year 1907 show a credit balance of £31,995 in addition to £11,044 brought forward from last accounts. After paying debenture interest, interest on second mortgage preferred stock, and transferring the sum of £7,500 to first mortgage debenture redemption fund, a dividend

Digitized by Google

is recommended for the past 3½ years on the preference shares, thus clearing off all arrears, and the sum of £5,576 is carried forward.

At the meeting on Monday, the report and accounts were adopted.

MANSFIELD & DISTRICT TRAMWAYS.—At the ordinary general meeting at Mansfield last week, the report and accounts given in our last issue were adopted. The Chairman pointed out that the gross receipts had exceeded by several hundred pounds the estimates in the original prospectus, and the expenses had been only slightly higher. The directors had under consideration the construction of an additional short length of tramway, but the shareholders could rest assured that the directors would not sanction any additional capital expenditure unless they were perfectly certain that it would materially add to the company's revenue.

NORTHAMPTON ELECTRIC LIGHT.—At the annual meeting on Thursday, the report and accounts given in our issue for February 27th were adopted. The chairman pointed out that owing to the adoption of metallic filament lamps, there had been a great shrinkage in consumers' bills, although the number of consumers had increased from 975 to 1,083.

NORTH METROPOLITAN ELECTRIC POWER SUPPLY.—The report for the year ended December 31st last, states that the revenue for the year amounted to £59,373, and the expenditure to £36,252, leaving a balance of £23,120. After deducting £4,000, placed to the credit of the depreciation and renewals fund, there remains £19,120 to be carried to the net revenue account. This balance of £19,120, together with sundry receipts and the amount brought forward from the previous year, make up the sum of £20,505. After providing for debenture and loan interest and other charges shown in the account, there is a balance of £12,672. The directors recommend a dividend at the rate of 4 per cent. per annum, and that £386 be carried forward. The name of the depreciation and reserve fund formed out of the profits for the year ended December 31st, 1906, has been changed to "Depreciation and Renewals Fund," to meet the requirements of the Board of Trade. The capital expenditure during the year amounted to £33,415, and has now reached a total of £433,820. During the year £3 per share was called up on 25,740 shares, making these shares fully paid, and a further 10,000 shares of £10 each have been issued, upon which £5 per share has been paid. The paid up share capital at December 31st, 1907, was £350,020. £126,500 5 per cent. mortgage debentures were sold in July, 1907, being part of a total authorised amount not to exceed one-third of the share capital for the time being actually issued upon which one-half has been paid up. At December 31st last £78,100 had been received in respect of such sales. The total number of units sold during the year amounted to 11,183,316, which, compared with the previous year's figure of 7,999,367, is an increase of 3,183,949 units (approximately 40 per cent.). An agreement having been entered into with the Corporation of the City of St. Albans for the incineration of the city's refuse, the erection of a generating station and refuse destructor is proceeding at St. Albans for this purpose, and also to enable the company to give a supply of electrical energy in bulk under the St. Albans Electric Lighting Order, 1898. The company has joined the British Electrical Federation, which has been formed by various electric traction and lighting companies for the purpose of co-operation and joint action in matters of common interest. The company's investment in the North Metropolitan Electrical Power Distribution Company, Ltd., has during the year been increased to £47,070, upon which a dividend of 2 per cent. will be received, calculated from the date of payment. The meeting is on March 24th.

OXFORD ELECTRIC.—The seventeenth ordinary general meeting was held at Oxford, March 6th. The Chairman, Sir Henry Mance, presided, and the report and accounts given in our issue for February 27th were adopted. The accounts showed, he said, that the capital had been increased by the issue of 2,500 preference shares of £5 each during 1907. The shares were rapidly taken up; in fact, they were subscribed for three times over. The directors do not see the necessity for issuing further capital at present. They had put down a 500-kw. alternator and high-tension switch-boards, and all the switch-boards which were erected 16 years ago had been carefully overhauled and remodelled, in order to comply with the regulations of the Home Office. The chief engineer had been carefully experimenting with appliances to ascertain if a cheaper kind of coal could be used, and although they were not yet in a position to speak decisively, they believed that the results obtained will be satisfactory. The older boilers, some of which have been working 15 years, have been thoroughly overhauled. Considerable expense had been incurred to lay feeder cables to the north of Oxford, in order to regulate the pressure in that part of the city. Arrangements have been made with the promoters of the Oxford Tramways Co. for a supply of electrical energy.

SHEFFIELD GAS.—At the ordinary general meeting last week, Mr. W. Mappin, vice-chairman, who presided, made some remarks in which he compared gas with electricity. He stated that at the last meeting of the Corporation a statement was made that the lighting of the Glossop Road Baths by electricity was costing £120 per annum, whereas formerly the cost of lighting by gas was only £40 per annum. It did not seem right that the ratepayers' money should be wasted in this manner, and as one of the chief ratepayers in the town, the Gas Company felt they had a grievance. Referring to one or two places elsewhere, he stated that in Islington 20 miles of road were lighted by electricity at a cost of £5,245, whereas 100 miles were lighted by gas at a cost of £4,077. If the 20 miles now lighted electrically were changed to gas, the cost would be £1,049. In Camberwell, he said, the street lighting cost £90 per mile per annum for gas, and £170 per mile per annum for electricity. The Borough Surveyor for Deptford had pointed out that the cost of one arc lamp would be £15 per annum, against five incandescent lamps for the same amount, and gas in London was more than double the price it was in Sheffield. He concluded by stating that he mentioned these matters in order that the Corporation might reflect before increasing the lighting rate of the city unnecessarily.

VICKERS, SONS & MAXIM.—The directors' report for the year 1907 recommends a dividend at the same rate as last year, after providing the usual liberal deductions for depreciation, &c., and writing the sum of £150,000 off "goodwill and patent rights," reducing this item in the balance-sheet to £100,000. The meeting is on the 20th inst.

NEW COMPANIES

BRITISH FLEXLUME SIGN CO.—Registered on February 27th, with a capital of £20,000 in £1 shares (6,600 8 per cent. non-cumulative preference), to acquire certain patents relating to improvements in illuminated signs and sign letters, to adopt an agreement with R. R. Wiley, J. C. Plimpton, and S. R. Kirkness, and to carry on the business of manufacturers of and dealers in illuminated and other signs and sign letters, glass, aluminium, lead, iron, steel, brass, and other metals, electricians, gasfitters, sanitary, electrical and mechanical engineers, &c. No initial public issue.

ELLWOOD & SLEDMERE.—Registered on February 25th, with a capital of £10,000 in £1 shares, to acquire the business carried on at 53 Mortimer Street, London, and elsewhere as Ellwood & Sledmere, to carry on business as designers, manufacturers of and dealers in cabinet works, household furniture, leather goods, hardware, jewellery, plated goods, ironmongery, turnery, and other household and electric fittings and utensils, house decorators, electrical engineers, and contractors, &c., agents in the United Kingdom, India, the British and other Colonies, and elsewhere. No initial public issue.

HIRST MAGNETO CO.—This company was registered on February 21st, with a capital of £2,000 in £1 shares, to carry on the business of manufacturers of and dealers in motor cars and self-propelled and other vehicles and machines of all kinds, electrical, mechanical, and general engineers, founders, fitters, &c. The subscribers are:—M. Grunebaum, J. F. Toohig, W. C. Page, T. Burrett, A. Pollock, A. W. Harris, A. Hirst. No initial public issue. The number of directors is not to be less than two nor more than four; the first are J. F. Toohig (permanent) and A. Hirst. No qualification necessary. Remuneration (except managing director), £80 per annum, divided.

NEW LOWCA ENGINEERING CO.—This company was registered on February 12th, with a capital of £25,000 in £1 shares, to adopt an agreement with J. Burns, C. Walton, H. Bentley, and J. N. Bentley, to acquire the business of the Lowca Engineering Co., Ltd., and to carry on the business of electrical, mechanical, civil, and general engineers, engine builders, and fitters, boiler and machinery makers, steel converters, founders, &c. The subscribers are J. Burns, J. Fearon, J. R. Bleasdale, J. Chatt, T. Fisher, C. C. F. Walton, H. Bentley. No initial public issue. The number of directors is not to be less than two nor more than five. The first are H. Bentley, C. Walton, and J. Burns. Qualification £500. Remuneration £200 per annum, divided. Registered office, Lowca, near Whitehaven, Cumberland.

PRADEAU MOTORS.—Registered on February 27th, with a capital of £1,000 in £1 shares, to adopt an agreement and to carry on the business indicated by the title and that of electrical and mechanical engineers, saddlers, rubber and tyre manufacturers, smiths, &c. No initial public issue. Registered office, Finsbury House, Blomfield Street, E.C.

TRACTION BATTERIES.—Registered on February 25th, with a capital of £1,000 in £1 shares, to buy, sell, import, export, manufacture, repair, let on hire and deal in batteries, galvanic cells, motors and electrical or other machinery, motor and other vehicles, &c. Among the subscribers are A. F. Sims (solicitor), F. H. March, A. N. D. Smith and A. Laban, chartered accountants. No initial public issue. Registered office, 6 Victoria Avenue, Bishopsgate, E.C.

SUMMARY

A report has been issued by the Parliamentary Committee of the London County Council dealing with the three Bills relating to electric supply which are before Parliament this session, namely, the London and District Electricity Supply Bill, the London Electric Supply Bill, and the London (Westminster & Kensington) Electric Supply Co. Bill. Deputations have been heard from the promoters of the first two Bills, and representations have been made by the Borough Councils of London in regard to the three schemes. The Committee state that they see no reason why the Council should depart from the view which it has hitherto held, that the most satisfactory solution of the question is to be found in a principal generating station in a favourable situation. It is recognised that there may be advantages in the London Electric Supply Bill if this measure could be so limited as not to be inconsistent with or unduly hamper a large scheme; and if linking-up powers in any form are granted to the companies, similar powers should be granted to local authorities. With regard to the London and District Electric Power Bill, the report states that provision should be made in the Bill for, say, £1,000,000 of the capital to be raised within twelve months, and for the works to be substantially commenced in two years. Provisions in this Bill with regard to purchase and limitation of dividends are considered unsatisfactory, and the Committee agree with the suggestion made by Mr. Lloyd George that a conference between all parties concerned should be arranged. (Page 463.)

The Motor-Car Exhibition now being held at the Agricultural Hall contains only a small proportion of electric cars and accessories of electrical interest. (Page 464.)

The discussion on the advisability of standardising fuses is continued in our correspondence columns by Mr. A. H. Dykes, who thinks there is no general demand for such standardisation, and Mr. F. Broadbent, who goes into the variations in the requirements of fuses for different classes of work, and points out that before the fuses themselves can be standardised, a standard set of conditions to be complied with must be formulated. As we go to press we have received a letter from the Union Electric Co., calling attention to the fact that they have standardised a series of no-voltage releases for polyphase motor switches; and a long letter from Mr. H. Laws Webb answering Mr. Bennett's letter in our last issue. (Page 464.)

The report of Messrs. W. B. Peat & F. W. Pixley upon the accounts of the London County Council Tramway Department, which they have investigated

Digitized by Google

from a "commercial" point of view, has now been issued. Exception is taken to the amount which has been laid aside to provide for the obsolescence of the horse tramway system, and the opinion is expressed that the amounts which have, from time to time, been applied to the relief of rates, should have been reserved on this account. The approximate loss under this head which they regard as still to be provided for exceeds £1,000,000. The amounts credited to renewals and reserve fund are also criticised, and the opinion is expressed that an insufficient amount is being allowed under this head. Amongst other matters, the question of the allocation of expenditure on street improvements is dealt with. The report was discussed at the meeting of the Council on Tuesday. (Page 465.)

A comparison between the installation rules of the Society of German Electrical Engineers (Verband Deutscher Elektrotechniker) and those of the Institution of Electrical Engineers was contained in a Paper read by Mr. W. P. Steinthal last Thursday before the Leeds Local Section of the Institution of Electrical Engineers. The differences discussed included those in the specifications of insulation, and the different conditions under which pure rubber-covered wires are used were commented on. The multiplicity of rules in this country was deplored in the discussion, and it was remarked that the German rules were consistently enforced. (Page 467.)

A form of arc lamp pillar for centrally-hung arc lamps, with a long hinged bracket-arm which can be lowered for trimming, is in use near Paris. (Page 468.)

The Poulsen wireless telegraphy station, situated at Lyngby, near Copenhagen, was enlarged last summer, and the height of the aërial was increased. This station is in communication with Newcastle, Berlin, and St. Petersburg. The generating plant consists of a petrol engine coupled to a 10 kw. dynamo, which supplies a single arc-gap. To supply the inert gas, with which the arc is surrounded, a few drops of alcohol are introduced into the arc-chamber every second. This renders the use of a complicated hydrogen generator unnecessary. (Page 469.)

The annual report of the National Physical Laboratory has been issued, and consists of a full account of the work done in all departments. The work proposed for this year includes the installation in the photometric department of a new set of electrical sub-standards for working with metallic filament lamps, and of an arrangement for determining the mean candle-power without rotating the lamp itself. Experiments in the determination of oscillation frequencies in wave telegraphy are also to be made. (Page 469.)

A considerable degree of success has attended the first year's working of the accumulator-driven motor-coaches recently put into service by the Prussian State Railways for local traffic. The total costs are given as 7·5d. per car-mile, including depreciation and interest on capital. Several more cars of a similar nature are on order. (Page 470.)

The switchboard which forms a part of the new extensions at the Wolverhampton Electricity Works is of the high-tension type, with all the actual high-tension apparatus in concrete cells, separated from the board itself by a passage-way. The operating panels are vertical, and carry also the excitation bars. Special arrangements are adopted for protecting the windings of the converting plant from abnormal rises of pressure. (Page 471.)

In a Paper read on Monday before the Society of Road Traction Engineers, Messrs. P. Trot Smith and W. A. Stevens alluded to the lack of financial success which has attended the use of the gear-driven petrol omnibus, and described a vehicle with electrical transmission gear, by the adoption of which they hope that the operating expenses will be very materially reduced. (Page 475.)

In an interesting Paper in the *Proceedings* of the Bristol Naturalists' Society on the effect of electricity upon plants, Mr. J. H. Priestley gives a historical review of the earlier experiments, and follows this with a detailed and quantitative account of the large scale trials made by Mr. J. E. Newman, resulting in a clear demonstration of the beneficial action of the electric discharge. Some further experiments by the author are also described. (Page 477.)

Tests have been made on one of the large single-phase turbo-alternators in the Electricity Works at Frankfort. Very low steam consumption figures were obtained. (Page 480.)

In the Paper by Dr. W. E. Sumpner and Mr. J. W. Record, read before last Thursday's meeting of the Institution of Electrical Engineers, the latest forms of iron-cored alternating-current instruments developed by these authors were described. One of these is a combined wattmeter and voltmeter, in which a swinging coil supplied by a current from a special transformer moves in the field of a shunt-wound alternating electromagnet with a laminated core, and another is a phase meter with a fixed iron core and light unrestrained moving coil. The mathematical theory of these instruments has been fully worked out, and is embodied in a previous Paper by Dr. Sumpner. Considerable admiration for the new instrument was expressed in the discussion, especially by Mr. S. Evershed, although a few disadvantages as compared with the dynamometer type of wattmeter were pointed out by Mr. K. Edgecumbe. Prof. E. Wilson compared Dr. Sumpner's method with other systems of power measurement on a mathematical basis; and Dr. Drysdale neatly demonstrated how the new instrument might be looked upon more as a special case of the induction wattmeter than as a real moving coil apparatus. One or two other speakers addressed the meeting, but owing to the excessive length of the remarks of some of the first speakers, several gentleman had to communicate their remarks subsequently. (Page 481.)

Professor F. Haber has carried out a careful series of experiments in order to ascertain whether porcelain heated until it becomes a conductor obeys Faraday's laws. As the result of his experiments, he finds that this is the case. It would appear that aluminium silicate, which is the main constituent of porcelain, acts very similarly to cryolyte in the electrolysis of aluminium. In the case of aluminium, the alumina is ionised in the cryolyte. In the case of porcelain the various metallic oxides are ionised in the aluminium silicate. Under "Electrochemistry and Electrometallurgy" we also draw attention to the formation of lead peroxide electrodes upon carbon, to the production of oxygen and hydrogen, to a modification of the thermit process, and to the use of aluminium vessels with acid solutions. (Page 487.)

At the Royal Institution on Saturday last, Prof. J. J. Thomson delivered the third lecture on "Electric Discharges through Gases," and showed how it was possible to freeze out the conducting portion of a gas, as at ordinary pressures the conducting particles were heavier than the molecules of the gas itself. A report of the lecture is given under "Electrical Science," together with an abstract of a Paper on the scattering of beta-rays by matter. In the Papers abstracted in the Continental Section, Rossi describes an improved magneto-elastic detector; Rüdenberg investigates the working of wireless receivers; Branly describes four methods of increasing the sensitiveness of electrolytic detectors; and Ries discusses the photo-electric sensitiveness of selenium. (Page 487.)

Digitized by Google

A patent specification by J. H. Webb, describing an improved method of signalling by continuously-generated electric oscillations, was published on Thursday last. Two specifications by B. G. Lamme, relating to methods of obtaining regenerative action with single-phase commutator traction motors of the series type, were also published. One by F. P. Driver describes a method of cementing filaments to the leading-in wires of incandescent lamps; and another by E. Heitmann and F. W. Young relates to magnetic wedges for armature slots of alternators and induction motors. (Page 489.)

The conference between the committee of objectors to the proposed Home Office regulations and the advisers to the Home Office, was continued on Thursday and Friday last week, with the result that an agreement was arrived at with regard to the remaining regulations from No. 20 onwards, the previous ones having already been agreed upon. The inquiry before Mr. Swinburne was resumed on Tuesday. Mr. W. H. Patchell gave the results of some interesting experiments of the effect of voltage and current upon a number of experimenters, including himself. These results are set out in the shape of two curves in our report of the proceedings this week. Mr. C. P. Sparks, on behalf of the London Electric Lighting Companies, followed Mr. Patchell on the question of the limit of voltage in the regulations; so far as alternating current was concerned, he said that there might very well be no limit at all, as no commercial alternating current system was in use at a lower pressure than 65 volts. With regard to the pressure of 130 volts for continuous current, he pointed out that there are, in London, cases in which direct current supply is being given below 130 volts in competition with alternating current, and whereas the alternating current supply will come under the regulations, the direct current supply would not. Lord Robert Cecil addressed the Commissioner on behalf of the London Electric Lighting Companies, and in effect stated that, whilst an agreement had been come to with regard to the details of the regulations, the electrical industry generally felt that it would be much better off without any regulations at all. On the question of whether existing work should come within the regulations or not, Lord Robert Cecil urged that a similar regulation to No. 55 of the Coal Mines Regulations should be added. This gives an appeal to an independent arbitration from the decision of an inspector as to whether the existing work complies with the regulations or not. Mr. Vesey Knox addressed the Commissioner on behalf of the various power companies in the North-East of England, and also for the Mersey Docks and Harbour Board, and suggested that the scope of the regulations should be limited as much as possible, and to this end they should not be made applicable to factories and workshops. He could recall no case of such an important industry as the electrical industry being called a dangerous trade, and he could conceive no other result than that the regulations would have the effect of seriously retarding progress if they were allowed to go forward in their present form. The inquiry concludes to-day, and a full report of the final proceedings will appear in our next issue. (Page 491.)

Mr. J. Christie reports that the repairs to the Shoreham Harbour and Southwick Electricity Works are now complete, and in his opinion everything is now quite safe. The proposal to construct an electric tramway in connection with the Edinburgh Exhibition has been rejected by the Corporation. There is still a great deal of discussion as to the tramway track in Hanwell. The letter received from the United Tramways Co., defending the condition of the track, has been characterised by the District Council as a gross misstatement of the facts. Arrangements have been concluded between the Oxford tramways and the National Electric Tramways Co., whereby the shareholders of the existing company will get a return of 72 per cent. of their capital, 60 per cent. of which will be paid in cash. Complaints have been made as to the danger arising from live studs from the Mexborough, Rawmarsh, and Swinton tramway system, and a conference is to be held on the subject. The extensions of the West Ham tramways to Iron Bridge, Canning Town, are to be proceeded with. (Pages 493–495.)

At the meeting last week of the City of London Electric Lighting Co., the chairman stated that the net revenue showed an increase of £12,775, in spite of the fact that the sales to the London County Council tramways in 1906, which amounted to over £5,000, did not appear in the accounts for 1907. Notwithstanding the higher cost of coal, the works costs had been reduced by 0·2d. per unit. Over six million units had been sold during the year for power purposes. At the annual meeting of the North Metropolitan Electric Power Supply Co., the chairman called attention to the large increase of business during the year, including the bulk supply, which was now being given to the Hendon Electric Supply Co. The slight increase in expenses was mainly due to the higher price of coal. Applications have been invited during the week for £600,000 4½ per cent. debenture stock by the Charing Cross, West End and City Electricity Supply Co. (Pages 496–498.)

The result of the long inquiry, presided over by Mr. James Swinburne, F.R.S., relating to the proposed new Home Office Regulations, which concludes to-day, has been that a number of alterations suggested by the many objectors to the form in which the rules were originally drafted have been considered, and considerable modifications have been introduced into the majority of the proposed regulations. The wise course of delegating to a committee of the objectors the task of drawing up the revised form of the regulations, given in another column, to which they would agree, has considerably shortened the work of the inquiry itself. In saying that the objectors agree to this final form, it must be borne in mind that they still hold to the opinion that regulations of the nature proposed are unnecessary; but if they are compelled to accept them, they regard the revised details as being of a more suitable character than those first proposed. It is right to point out that the Home Office has gone a long way to meet the objectors in the case of most of the regulations to which serious opposition was offered, except as regards the question of the limits of voltage below which the regulations are not to apply. In respect to these limits as they now stand, the somewhat anomalous fact was brought out by one of the speakers on Tuesday that in a case where a 110-volt continuous-current system was established at a place where it was in competition with an alternating-current system working at about the same voltage, the latter would be handicapped by being obliged to conform with restrictions from which the former would be free. The difficulties which present themselves when any attempt is made to standardise the dangers of electrical circuits were well brought out by Mr. Patchell, who in his evidence described a series of experiments on the effects of certain voltages upon different persons and under different circumstances. The curves which we reproduce show clearly how very wide is the variation in the effect of the same voltages upon different people, and how impossible it is to define a sharp limit to the

Digitized by Google

range of voltage which is dangerous. In considering the alterations which have been made, attention may be called to the modification in the much-discussed Regulation 17, by which the dimensions specified for switchboard passage-ways will not apply to existing installations, and also to the concession as to the minimum width of passage-ways in the case of high-tension switchgear. Considerable stress was laid on Tuesday and Wednesday upon the necessity for an appeal to a technical arbitrator from the decision of a factory inspector under the new regulations, although there appeared to be some difference of opinion as to the exact form such appeal should take. We look forward with interest to the final decision of the Home Office when they have considered the results of the inquiry, which the Commissioner will lay before them.

THE report of Messrs. W. B. PEAT and F. W. PIXLEY upon the accounts of the Tramway Department of the London County Council, which we reprint at some length in another column, has been awaited with a good deal of interest, as representing the views of independent professional accountants upon matters about which there has been considerable controversy. Previous discussions on the tramway question have always been so strongly flavoured with party bias that it is a relief to read the clear and dispassionate, although perhaps strongly worded, criticisms contained in the report. It is the business of the auditor to be on the safe side with his figures, and we are not surprised at the expression of opinion that the provision made for the obsolescence of the horse-tramway system has been on too small a scale, and that the money which has been, so to speak, returned to the ratepayers in the form of relief of rates ought properly to have been employed in writing off unsecured or insufficiently secured capital. The estimation of the amount to be written off in this matter is not a simple matter of arithmetic, but there are factors which vary according to the point from which they are viewed. It is urged by those who defend the accounts as they stand that, in addition to the "scrap value" of the track and cars, the capital sunk is still represented by a real asset in the form of the right of running tramways along certain streets and receiving the profits resulting from the traffic. The question is a large one, and will probably eventually resolve itself into a compromise. The matter of arrangements for a renewal reserve fund has been discussed and reported upon in connection with other undertakings times without number, and here again the auditors apparently desire to be on the safe side. They are evidently frightened by the table of increasing cost of repairs per mile, which they have included in their report, but we think it should be pointed out that this is only natural in a young undertaking, in which all the plant has not yet completed its first cycle of wear and repair. Another point considered is the knotty question of the allocation of the cost of street improvements among the various books at Spring Gardens, but the conclusions arrived at are not as sharply defined as the opinions expressed in the rest of the report. The general trend of this rather pessimistic report, whether its figures are too high or too low, is to show that the L.C.C. tramway system is not yet so free of the burdens of the colossal capital expenditure which called it into being as has been represented. In troubles of this nature it is not, however, alone among London traffic organisations which are still in the early days of their altered conditions. But as it is in the happy position of having to pay no dividends to its shareholders, there need be no undue haste in allotting profits to the relief of rates so long as the stale items on the capital account remain to be written off, or so long as there can be the least anxiety as to the sufficiency of the renewals reserve fund.

ARRANGEMENTS FOR THE WEEK

(TO-DAY) THURSDAY, MARCH 26TH.

Royal Institution.

3 p.m. Afternoon Lecture II., by Dr. R. T. Glazebrook, F.R.S., on "Standardisation in Various Aspects: (2) Electrical Engineering."

Royal Society.

4.30 p.m. Meeting at Burlington House. Among the Papers to be read is one by T. Mather, F.R.S., and F. E. Smith, on "Note on the Values of the Board of Trade Standards of Current and Electromotive Force."

FRIDAY, MARCH 27TH.

Physical Society.

5 p.m. Meeting at the Northampton Institute, Clerkenwell. Dr. C. V. Drysdale will read notes on the following subjects:—(1) On the Plug Permeameter, (2) On the Use of Shunts and Transformers with Alternate-current Measuring Instruments, (3) Wattmeters, (4) Experimental Demonstration of Alternate-current Wave Propagation in a Helix.

Electro Harmonic Society.

8 p.m. Last Smoking Concert of the Season at the Great Hall, Cannon Street, London, E.C.

Royal Institution.

9 p.m. Evening Discourse by the Hon. R. J. Strutt, F.R.S., on "Radio-active Change in the Earth."

SATURDAY, MARCH 28TH.

Royal Institution.

3 p.m. Afternoon Lecture IV. on "Electric Discharges through Gases," by Prof. J. J. Thomson, F.R.S.

Institution of Electrical Engineers: Students' Section.

10 a.m. Visit to the Thames Ironworks.

TUESDAY, MARCH 31ST.

Institution of Electrical Engineers: Manchester Local Section.

7.30 p.m. Meeting in the University. Paper to be read:—"Electrolytic Corrosion," by Prof. W. H. H. Gee.

Finsbury Technical College Old Students' Association.

8 p.m. Smoking Concert at Anderton's Hotel, Fleet Street, London.

THURSDAY, APRIL 2ND.

Institution of Electrical Engineers.

8 p.m. Ordinary General Meeting at 25 Great George Street, Westminster, S.W. Paper to be read:—"High-speed Electrical Machinery," by G. Stoney and A. H. Law.

Civil and Mechanical Engineers' Society.

8 p.m. Meeting at Caxton Hall, Westminster, S.W. Paper to be read:—"Efficiency of Boiler-heating Surface," by C. H. Wingfield.

Telegraph Traffic.—The French Co.'s cable between Martinique and Guadeloupe has been restored to working conditions, but Guadeloupe cannot as yet be reached by the cables of the West India and Panama Co. The *viâ* Fao route was not working on the 18th, there being some derangement between Bagdad and Bassorah, which was remedied on the 19th inst. Connection has also been re-established with Alderney and the Channel Islands by the repair of the cable between Guernsey and Alderney.

LONDON ELECTRIC POWER BILLS

THE Parliamentary Committee of the London County Council has reported with regard to the three Bills dealing with electric supply before Parliament this session, viz., the London and District Electricity Supply Bill, the London Electric Supply Bill, and the London (Westminster and Kensington) Electric Supply Companies Bill. A *resumé* of the contents of these Bills was given in ELECTRICAL ENGINEERING, Vol. II., p. 1007, and we summarise the Committee's conclusions below.

Deputations from the promoters both of the London and District Electricity Supply Bill and the London Electric Supply Bill, have been received by the Parliamentary Committee, who have also heard representatives from the Borough Councils, both those having their own electrical undertakings and those having purchasing rights over the undertakings of companies within their areas. The scheme proposed by the London and District Electricity Supply Bill for a principal generating station on the river below bridges is in accordance with the Council's scheme of last session and the views accepted by Parliament, both when the Administrative Company's Bill was being considered in 1905, and in the report of the Select Committee on the Council's Bill of 1906. The promoters of the London Electric Supply Bill, on the other hand, urge that there is not now, and will not for some considerable time be, any necessity for a new principal generating station, and that if they are allowed to link up their existing stations they will be able to satisfy all demands as cheaply as could be done from a principal station. They lay stress on the point that the demand for electric energy for power purposes is not so great as has been supposed. This is a question upon which it is difficult for the Council to obtain the data necessary to arrive at a final conclusion. After advice by the officers and full consideration, the conclusion has been come to that, on the materials and facts at present available, there is no reason why the Council should depart from the view which it has hitherto held, that the most satisfactory solution is to be found in a principal generating station in a favourable situation. At the same time it is felt that every year's delay has increased the difficulties in the way of a new comprehensive bulk supply scheme, and that the most careful consideration should be given to any new facts which the promoters may be able to lay before Parliament. The Committee also recognise that there may be advantages to be obtained under the London Electric Supply Bill if it can be so limited as not to be inconsistent with or unduly hamper a large scheme, and the same remark applies to the London (Westminster and Kensington) Bill. It must necessarily take a considerable amount of time until the new undertaking is in operation, and in the meantime, according to the contention of the promoters, it will help to cheapen electric supply if existing undertakers are allowed to make the most of their plant and stations by linking up their systems. If linking up powers in any form are granted to the companies, similar linking up powers should also be granted to the local authorities if they are willing to take them in a Bill to be introduced next Session. The representation proposed to be given to the Council on the joint committee is not considered desirable, as it is not a sound policy for the Council to have representatives on the boards of management of private commercial undertakings. The London Electric Supply Bill also affords an opportunity for consolidating and making effective the purchase rights of local authorities over the undertakings of the existing companies, which at present are in many cases valueless, because the local authorities cannot purchase complete systems, but only such mains or stations as are within their areas. It is pointed out, however, that in some instances local authorities have at present purchasing powers before 1931, so that one effect of consolidation would be to postpone the date of purchase in those cases. Moreover, if the central authority had to purchase all the undertakings at one and the same time a larger sum might be required than could conveniently be raised in cash, so that it might have to be provided that the purchase consideration might be satisfied in stock.

The provisions for purchasing the undertakings of the joint committee and the existing companies are also regarded as unsatisfactory.

Dealing with the provisions of the London and District Bill, it is pointed out that in the first place it is essential that Parliament should be satisfied as to the financial ability of the promoters, and there should be a provision that the powers are to lapse, unless a considerable proportion of the capital, say, £1,000,000, is raised within twelve months, and unless the works have been substantially commenced within two years. No objection can be taken to the maximum prices, inasmuch as these are, as pointed out above, similar to those in the Council's own Bill, but the power of asking for periodical revision of prices should also be given to the Council. The purchase clause in the Bill is regarded as quite unsatisfactory. Under it the purchasing authority might have to pay large sums in respect of wholly obsolete and valueless plant, and the terms of purchase at the end of 42 years should, as in the case of the Administrative Company's Bill of 1905, be those provided by the Electric Lighting Act, 1888. There should also be a power to purchase in 1931, but in the event of purchase at the earlier date better terms would undoubtedly have to be conceded. The Committee also consider the provisions as to limitation of dividends unsatisfactory, and think that there should be substituted for it a sliding scale of prices and dividends subject to revision by the Board of Trade.

With regard to the position of existing electrical undertakings, the Council is interested in this matter, inasmuch as upwards of £5,000,000 have been borrowed on the security of the rates for the purposes of such undertakings. The promoters of the London and District Electricity Supply Bill have stated that their object was to assist and not to compete with the existing undertakings and to that they should be strictly held. No doubt the main consideration is to obtain a cheap supply of electricity for London, but it is essential in the public interest that existing authorised undertakers who have taken the risk of establishing these undertakings should receive fair treatment. The Select Committee which reported on the Bill of 1906 also took this view. Objections are raised both to the clause in the present Bill and also to the "Kitson clause," which was in the Council's Bill of last session. The Committee hope that the County Council will be able to assist in Committee in settling a clause which will be acceptable and fair to all parties. There are cases when it would appear to be clearly in the interests both of the ratepayers in the particular borough having an electric undertaking and the consumers of electric current that a supply should be taken from outside, *e.g.*, when the generating costs exceed the price at which energy could be purchased. Again, in most cases it would be more advantageous to take current from the new station rather than incur expenditure in increasing small existing stations.

The House of Lords passed a resolution in favour of referring these Bills to a Joint Committee of both Houses, but the House of Commons did not agree with the resolution, so that the Bills will come before Committees in each House in the usual way. In moving the House of Commons to disagree with the resolution of the House of Lords, Mr. Lloyd George said that there ought to be a conference between the parties to see whether agreement could not be come to. It is thought that the Council should co-operate in endeavouring to bring about a general agreement. The Committee therefore recommend—(*a*) That the Council do continue its opposition to the London and District Electricity Supply Bill on the lines indicated in the above report, with a view to obtaining such amendments and the insertion of such provisions as the Parliamentary Committee may think necessary or desirable in the interests of the public or the Council. (*b*) That the Council do continue its opposition to the London Electric Supply Bill and to the London (Westminster and Kensington) Electric Supply Companies Bill on the lines indicated in the above report, with a view to obtaining such amendments and the insertion of such provisions as the Parliamentary Committee may think necessary or desirable in the interests of the public or the Council.

Electrical Engineers Volunteers.—The Clyde division of the Electrical Engineers Volunteers held a supper and smoking concert at Greenock on Monday last week. The present strength of the division is four officers and 70 men.

A Steep Grade Electric Cable Railway.—The recently constructed electric cable mountain railway in the Southern Tyrol, near Bozen, known as the Virgl railway, is described in the *Street Railway Journal* as having the steepest gradient of any railway of its class. Formerly the Mendel Railway and the Mount Vesuvius cable line held first and second places respectively with maximum grades of 64 per cent. and 63 per cent., but the new line has a grade of fully 70 per cent. at its upper end, and in general averages 66 per cent. in a run 288 metres (about 945 ft.) long horizontally, and 195 metres (about 640 ft.) vertically. The road construction, however, is considerably lighter than the Mendel Railway, because the cars are smaller and the braking stress on the track less. The experiments in automatic vacuum braking made on the 70 per cent. grade showed that loaded cars freed from the cable could be stopped without shock within a length of 1·2 metres. The cable machinery is located in the upper station, and is driven by a 55-h.p., 550-volt, three-phase motor, operated by current transmitted at 3,450 volts from a power plant in the valley. The station machinery is operated at a speed to permit the cars to make the trip in five minutes. Hand and automatic brakes are in the station for the control of this machinery. Automatic braking occurs whenever the speed of the machinery rises 15 to 20 per cent., when a car goes beyond the upper stopping point, when there are interruptions in the power supply, and in other contingencies. In every application of this automatic brake the power circuit to the motor is broken. The electrical equipment was supplied by the A.E.G. Co., of Vienna.

MOTOR-CAR EXHIBITION AT THE AGRICULTURAL HALL

IT is more than ever to be regretted this year that a means of harmonising the conflicting interests which result in the continuance of more than one group of automobile shows in the year in London has not been arrived at. Owing to this multiplicity of exhibitions, the Agricultural Hall Show opened last Saturday, coming as it does not very long after the magnificent show of private cars held at Olympia by the Society of Motor Manufacturers and Traders, and practically clashing with the exhibition of commercial vehicles promoted by the same Society, cannot possibly claim to be representative of any class of the automobile industry, and we were surprised to see a considerable amount of the space filled up by second-hand cars.

The lack of exhibits of either importance or novelty was also intensified during the first days of the Show by the lamentable unpreparedness of the majority of the stands. A glance round the Hall reveals only one stand devoted to electric cars, and an entire absence of the petrol-electric vehicles which have formed a marked feature of more than one recent exhibition; nor in the section devoted to accessories is any great novelty shown.

The Electric Vehicle Company, 1 Earl Street, S.W., show, in the ample space allotted to them, five or six electrically-propelled vehicles, all of which are, we believe, of American design. These range from a 2-ton van to a what is perhaps a novelty in this country, in the shape of an electric carrier tricycle. In this latter a small motor, ingeniously suspended in a framework, which also acts as a radius-rod, drives the single rear wheel through a bevel gear. The batteries are contained in a part of the usual carrier box between the front wheels. A small phaeton and a landaulette are also shown.

The gallery, as on previous occasions, is partly devoted to accessories. Amongst the electrical exhibits may be mentioned a collection of Siemens-Obach dry cells for ignition purposes, shown by Messrs. Siemens Brothers & Co., of 12 Queen Anne's Gate, S.W., and some new patterns of coil on the stand of the Prested Miners' Gas Indicating Electric Lamp Co., Ltd., of Elthorne Road, Holloway. The latest Prested coil is on the single trembler system, although a low-tension commutator is retained, and separate coils are employed for each cylinder. By this means as good synchronisation can be obtained as with a high-tension distributor without its disadvantages, and there is less strain on the coils than when a single coil does duty for all the cylinders. In one form of the coil a pair of tremblers are provided, with a change-over switch, and these, with their actuating magnets, can be placed, if found convenient, in a separate box from the coils themselves. The same firm also show an ignition accumulator of their own manufacture, with an improved form of plate.

Among other exhibits in the gallery is Hay's electrically-heated vulcaniser for tyre repairs, shown by Maison Talbot, of 1 Long Acre, W.C. This apparatus is much more compact than the ordinary spirit-heated vulcaniser, and we understand that the requisite vulcanising temperature, which is about 280° F., can be obtained in 10 minutes from an ordinary 4-volt, two-cell ignition accumulator, and it is said that overheating is impossible.

Various electrical appliances for motor-cars are also shown in the gallery by Messrs. W. & R. Jacobs, of 39c King William Street. These comprise a British-made accumulator, known as the "Electary," which is fitted with a special form of incorrodible terminal coils, switches, voltmeter, &c., and a special series of head, side and tail lamps for motor-cars and cycles, in which 4-volt or 8-volt Osram lamps are used. A few electrical accessories are also shown in the arcade near the entrance. On the stand of Messrs. J. C. Lyell & Co., of 55 Victoria Street, S.W., may be seen, among other exhibits, a special change-over switch, which allows of the employment of magneto or coil ignition at will, with only one plug per cylinder, and some examples of the M.S. low voltage metallic filament lamp for carriage lighting. The lamps, having an efficiency of about 1·2 watts per candle-power, consume less than half the current of an ordinary small carbon filament lamp, and give about twice the light. Another advantage of metallic filament lamps for use with batteries is that the diminution of light as the voltage of the battery falls off is much less than with carbon filament lamps. A new pattern of electric hand-drilling machine is also shown.

Messrs. Geipel & Co., of 92 St. Thomas Street, S.E., also exhibit in this section a number of instruments, including the well-known "Vulcan" electrical speed indicator, which consists of a small magneto-generator and a voltmeter, and other indicating instruments of the hot-wire type.

CORRESPONDENCE

THE STANDARDISATION OF FUSES.

To the Editor of Electrical Engineering.

Sir,—I have read with interest the note in your issue of the 12th inst., on the suggested intention of the Engineering Committee to deal with the question of electrical fuses. What is it intended to standardise—the type, the size, the fusing current, or the material? Unless one particular pattern be selected, it is obvious the other variables cannot be standardised, as the length depends entirely on the design. The ratio between the working current and the fusing current, again, depends entirely on the type, as what is a practicable ratio with one type of fuse is quite different with another. The number of different fuses on the market is legion, and, speaking generally, they mostly do the work required of them by practical men.

The Committee has done good work, and much remains for it to do, but I cannot help thinking that it is a mistake to spend time and money in dealing with articles for the standardisation of which there is no general demand, and, indeed, no felt want.

A. H. Dykes.

1 Victoria Street, London, S.W.
March 18th, 1908.

To the Editor of Electrical Engineering.

Sir,—Whilst, as I pointed out in my Institution Paper on Wiring Rules in 1901, too much standardisation tends to retard progress, yet a certain amount is a necessary evil for commercial considerations. Before we can standardise fuses we ought to formulate a standard set of conditions to be complied with. These would tend to bring about some kind of uniformity in distribution-box design, for, as Mr. Russell points out, the standardisation of fuse-box design is perhaps more urgent than the question of the standardisation of the fuses themselves. What I should like to see is the adoption of a standard length of fuse, so that fuses of various carrying capacities could be used alongside each other in the same box, a practice which is, of course, diametrically opposed to the idea of non-interchangeability of fuses, standard minimum spacing distances between fuses, minimum standard clearances between live metal and case, and some uniformity in the method of leading the wires into and out of distributing boxes.

As to the standardisation and interchangeability of fuses, this is, if not impracticable, at any rate most undesirable. This point does not, perhaps, affect lighting fuse-boxes to the same extent as motor fuse-boxes. In the case of lighting, the ultimate carrying capacity of any branch circuit can be settled once for all when the installation is first laid down. But in the case of motors, which in well-arranged installations are individually fed from a separate pair of fuses in a distribution fuse-box, there is no such guarantee. It is often necessary to increase the size of the motor, and consequently the carrying capacity of the fuses. Again, motors of various sizes are fed from one fuse-box, involving fuses of widely different carrying capacities. It is essential, therefore, that the fuse-gaps—that is, the centres between the fuse-clips—should be of the same dimensions for a wide range of fuse sizes.

The spacing also is an important matter. It is not at all uncommon for several adjacent motor fuses to blow, due to arcing over from one to another. This applies, of course, to the open type of fuse. Wher cartridge-type fuses are used, it is desirable that the fuse-boxes should be ventilated. The amount of heat given off, say, by a dozen pairs of cartridge fuses in motor circuits is often sufficient to injure the insulation of the leading-in wires if the boxes are fairly airtight.

Digitized by Google

The essential requirements for the fuses themselves are that they should be capable of being easily replaced or attended to without any risk of shock or burn to the attendant; that there should be no possibility of connections becoming slack; that in motor circuits they should have a considerable time element—that is, they should be able to take very large overloads for sufficient time to permit of a motor being started up quickly; in the circuits of induction motors the fuses should stand four or five times their normal current for about half a minute to permit of starting up, but the motor should be protected against continuous overload.

The main fuses on an installation should carry an overload for a longer period than the branch fuses. Many cases have come under my experience in which main fuses capable of carrying 200 amperes or so have blown, due to the switching on of a motor without the starting resistance being in circuit, when the motor fuse itself had not blown. This is due to the use of enclosed-type copper fuses in the motor circuits and open-type lead fuses in the main circuits. If there were some uniformity of practice as regards nature of fuse metal and type of fuses, *i.e.*, open or enclosed, this kind of thing would be to some extent overcome.

It is not uncommon to find motor fuses, particularly in printing offices, large enough to carry three or four times the full load current of the motor. This is necessary in order to permit of the motors being started up quickly. If the fuses had sufficient time lag this would not be necessary. As to the overload current which a fuse should stand, I do not think any hard and fast rule can be made. In motor circuits it depends to some extent on the type and rating of the motor. Some I should not care to overload more than about 20 per cent., whilst others will stand 100 per cent.

There is no need for a large margin in the fuses protecting lighting circuits, as the conditions are very different to motor circuits. But the fuses, particularly the main fuses, should have a considerable time element to permit of an instantaneous "short," due, say, to a bad lamp, whilst the continuous overload permitted should not exceed, say, 50 per cent.

Yours faithfully,

Frank Broadbent.

4 Queen Street Place, E.C.

L.C.C. TRAMWAYS ACCOUNTS

THE report giving the result of an investigation into the accounts of the London County Council Tramway Department, which has been conducted by Mr. W. B. Peat (President of the Institute of Chartered Accountants) and Mr. F. W. Pixley (a past President of the Institute), has now been issued. The investigation covers the period from 1892–3, when the Council commenced expenditure in connection with tramways, down to March 31st, 1907, the date of the last published accounts.

The report first deals with the horse-traction system. All the tramway undertakings acquired have been on the horse-traction system, with the exception of a small section worked on the cable system. In May, 1903, the Clapham to Tooting section was opened on the electric system, and this system of traction has been gradually superseding the horse-system. Owing to the supersession of horse-traction the original system of traction becomes obsolete as electrification proceeds.

The total net expenditure under this head up to March 31st, 1907, was £2,380,736, 13s. 1d. This debt is being repaid over the following periods:—60 years, £1.819,831 12s. 11d.; 25 years, £463.117 12s. 8d.; and 8 years, £97,788 7s. 6d. The debt outstanding at March 31st, 1907, was £2,010,902 7s. 4d.

The Council includes in its capital account up to March 31st, 1907, the outlay on both the horse-traction and the electric-traction tramways, the latter including the expenditure on street improvements, &c., namely:—Horse traction, £2,380,736 13s. 1d., and electric traction, £4.356,000 12s. 4d.

This principle in our opinion, continues the report, is not sound, because there are practically no existing assets to represent the horse-system of traction so far as it has been displaced. It is suggested that a certain residue of value exists in some of the displaced horse-traction assets, but, in our opinion, this value cannot alter the fact that there is a large loss not provided for on the displacement of the horse-traction system.

The original track cost £1,017,942 9s. 11d., to which must be added £23.826 3s. for payments to the tramway companies in respect of their expenditure on street improvements (included in purchase prices), and £13,827 6s. 11d. for additions by the Council. Deducting £27,944 8s. 8d. for proceeds of sales of old material, a balance of £1.027,651 11s. 2d. is left, which represents the track of the horse tramways displaced by the electric system. It is suggested to us that there is a residue of value in the track of the horse-tramway system in excess of the scrap value of the old materials, but no figure has been placed upon this residue—subject thereto, and to a proportionate amount of the sinking fund instalments which have been paid out of revenue, the above balance is a loss for which no provision has been made in the accounts of the tramways. Practically the whole of the debt in respect of the above expenditure is being repaid over a period of 60 years.

Parliamentary, law, and other costs, amounting to £77,533 8s. 11d. were incurred by the tramway companies, and it is reasonable to conclude that these expenses have now no value and subject to a proportionate amount of the sinking fund instalments which have been paid out of revenue the above amount represents a loss, for which no provision has been made in the accounts of the tramways. The goodwill relates to the horse tramways acquired by the Council, and was estimated by the valuer to the Council in apportioning the purchase prices of the various undertakings at £166.937 7s. 6d. The debt in respect thereof is being repaid in instalments at the end of 8, 25, and 60 years, and includes an item of £97,787 7s. 6d. paid to the North Metropolitan Tramways Co., as the consideration for cancelling the unexpired term of their lease from the Council, viz., 4 years. It is advisable that this £166,937 7s. 6d. should be written off out of revenue over a shorter period than is provided by the payment of the sinking fund instalments.

The net capital outlay on property and buildings is given as £773,318 8s. 11d.

Some of these buildings have been converted by the Council to other uses in connection with the electric system, and the leases in some cases have been disposed of or determined. Where the buildings have been made available for other purposes the expenditure has been rightly charged to the capital of the electric undertaking, but the capital displaced by demolition or reconstruction has not been written off, and remains part of the cost of the horse-tramway system. It is, in the circumstances, impossible to indicate what loss (if any) will arise in connection with the property and buildings.

The total cost of rolling stock was £126,232 0s. 7d., the realisations have been £3.657 5s. 2d., and the stock remaining is valued at £2.166, leaving an estimated loss of £120.408 15s. 5d., for which no provision has been made in the accounts of the tramways, subject to a proportionate amount of the sinking fund instalments, which have been paid out of revenue. The debt in respect of rolling stock is being repaid over a period of 25 years.

The estimated loss on machinery and plant, after deducting proceeds of sales and plant purchased in 1906 (mainly from the North Metropolitan Tramways Co.) at cost, was £55,060 5s. 4d., subject to a proportionate amount of the sinking fund instalments which have been paid out of revenue. Practically the whole debt is being repaid over 25 years.

The estimated loss on harness and equipment was £5.980 10s. 1d., subject to a proportionate amount of the sinking fund instalments, which have been paid out of revenue. The debt is being repaid over 25 years.

With the exception of the cost of temporary generating stations and other expenditure of a special and temporary nature, in all amounting to £43.885 4s. 4d., paid for out of revenue, the combined total net cost of the horse-traction system and the electric-traction system appears as an asset in the capital account. As already mentioned, the Council, apart from the repayment instalments of the debt charged against revenue, have made no provision for the loss on any of the foregoing items of permanent way, rolling stock, &c. While we recognise, continues the report, that the Council had no means of writing off at once the loss on the displaced assets of the horse system, we consider that such loss should be provided for out of revenue more rapidly than by the charging of the annual instalments in repayment of the debt. Until these losses are provided for there can be no profits applicable for relief of the rates.

Summarising the position as regards the loss on the displacement of the horse-traction system, we are of opinion that, even assuming that the freehold and leasehold properties and buildings are of sufficient value to represent the amount at which they stand in the accounts, and after allowing for any

Digitized by Google

residue of value which may remain in some of the other assets, the loss for which the Council will have to make provision, must approximate £1,500,000. Subject to the proportionate amount of the sinking fund instalments, in redemption of the debt, which have been paid out of revenue, and which, on the whole of the horse-traction debt, amounted on March 31st, 1907, to £369,854 5s. 9d., the approximate loss still to be provided for must exceed £1,000,000.

£293,592 2s. 11d. has been applied in relief of rates since 1897. This sum has been applied out of the earnings of the horse-traction system. We consider that these amounts should have been reserved towards the loss referred to above. Until the revenue of the tramways has been charged with (1) the losses on displaced assets of the horse system, (2) a full provision for renewals on the system now in force, (3) the charges in respect of the outstanding debt, and (4) a proportionate amount of the full Central Office charges, we are of opinion that no sum will be available for relief of rates. In the balance-sheet the loss referred to should appear as loss on conversion of the horse system to electric traction.

Passing on to electric traction, the total net expenditure to March 31st, 1907, not including the amount charged for street improvements, &c., is given as £4,076,184 16s. 10d. Of the the whole debt in respect of this £3,128,942 19s. 11d. is being repaid over 25 years and the remainder over 60 years. The debt outstanding on March 31st, 1907, was £3,853,376 8s. 5d. To the extent that the Works Department has been employed as contractors, actual cost only has been charged to capital, and no allowance made for profit to that department. This is quite in accord with our views of a proper basis of the capital charge.

The amount at the credit of renewals reserve fund on March 31st, 1907, was £141,855 1s. 3d., made up as follows :— Balance of amount set aside out of the horse-system profits to March 31st, 1903, £29,051 4s. 9d.; amount set aside out of electric-system profits from April 1st, 1903, £105,000; and interest and dividend accumulations, £7,803 16s. 6d. What provision should be made out of revenue for renewals of the electric undertaking is a very difficult question to decide when the life of the assets forming part of such undertaking has not yet been ascertained by experience. It is impossible for us to fix a rate. The Council has been advised by its officers that at least one penny per car-mile run should be provided for the renewals reserve fund, this being in addition to any general repairs of the undertaking and the renewal of the machinery, plant, and buildings of the generating stations. A charge for renewals is, in our opinion, essentially an element in the cost of the year's trading, and should not be determined or affected by the result of such trading. It should form a charge in the revenue account of each year before the balance of net revenue is arrived at. It should not be treated as an appropriation of any balance of revenue available. As an example of the erroneous method of dealing with this charge we refer to the accounts for the year ending March 31st, 1907. The surplus revenue is shown as £9,673 15s., but if one penny per car-mile had been charged for renewals, the tramway undertaking would have shown a deficiency of £58,107 5s. It is to be noted that the result for 1906-7 was exceptional, and consequent on the working of the remaining horse systems at a loss before charging interest on and repayment of debt. We are of opinion that revenue should be charged with the cost necessary to maintain the undertaking as a going concern, which can only be done by providing an adequate reserve for future renewals; otherwise, long before the termination of the loan periods, the undertaking will become an instrument incapable of making profit, because of the excessive repairs and renewals which will be necessary, and the absence of an adequate renewals fund out of which the cost of the renewals could be met. As having an important bearing on this point, the following table is given of the increase in ordinary repairs, &c., during the four years of the working of the electric system, as shown in the following statement :—

Year.	Total car mileage of the electric system.	Total net repairs, &c., of the electric system. £ s. d.	= Per car mile run. Pence.
1903-4 ...	4,469,576	15,060 8 6	0·808
1904-5 ...	10,931,396	40,988 10 0	0·899
1905-6 ...	12,164,292	57,842 15 10	1·141
1906-7 ...	16,267,579	89,429 7 8	1·319

It will be observed that 1906-7 shows an increase of ½d. per car-mile run over 1903-4. The inference to be drawn is that the increase in repairs inevitably points to the need for early renewal.

In our opinion it is essential that the whole of the renewals fund should be specifically invested so as to be available when required. We find that out of the Council's renewal fund of £141,855 1s. 3d. on March 31st, 1907, only £83,008 16s. 2d. had been so invested, the balance of £58,846 5s. 1d. having been used for the general purposes of the tramway undertaking. The renewals provision necessary to keep the undertaking as a going concern have, in our opinion, no relation to the statutory sinking fund.

With reference to the allocation of expenditure on street improvements, the authors of the report are of opinion that the proportion of the cost of the street improvements and widenings, which should be charged to the tramways, should bear a direct relation to the benefit derived or to be derived by the tramways. (*a*) When the improvements were undertaken wholly to accommodate the tramways and were not otherwise necessary. (*b*) When improvements were undertaken along a route concurrently with the construction of a tramway. (*c*) When the improvements were undertaken with the object of accommodating general traffic, and also providing a sufficient width of thoroughfare for a contemplated construction of tramways. (*d*) When the tramways, although constructed, derive in common with the general traffic benefit from the improvement.

With regard to (*d*), it may be urged that the tramways should not be charged with any improvement made subsequent to their construction, on the ground that an incorporated company owning a tramway system under a charter for a term of years could not be called upon to pay any portion of such expense. This may be true, but the incorporated company may run an inefficient service of trams, if it prefers to do so, rather than bear any share of the expense, whilst on the other hand the Council being responsible for providing facilities for both the general and the tramway traffic, the expenditure thereon should be apportioned according to benefits received. They are further of opinion that in assessing the benefit apportionable to tramways, the Council should be guided by the advice of experts who would take into account all the circumstances of each particular case. Some specific examples of street improvements are then considered.

In connection with the expenditure on *improvements undertaken or proposed in connection with tramway schemes*, the total expenditure up to March 31st, 1907, was £752,128 11s. 8d.; of this, £190,999 6s. 1d. has been charged to tramways, and £173,690 7s. 1d. has been contributed by local authorities, the remainder, viz., £387,438 18s. 6d., being charged to improvement account. A substantial, but as yet unascertained, proportion of this last figure, in the opinion of the authors of the report, should be charged to tramways capital account. The expenditure on *improvements for the purposes of general traffic* amounted at March 31st, 1907, to £1,007,103 11s. 2d., the local authorities concerned contributed £142,982 1s. 1d., the balance, £864,121 10s. 1d., being charged to improvement account. In their opinion a considerable, but as yet unascertained, proportion of this latter figure should also be charged to tramways capital account.

In considering the basis of the valuation of the tramway undertakings by the valuer to the Council, dated January 16th, 1907, the basis adopted by the valuer, viz., "of applying a multiplier to an ascertained net income," is stated to be a fair and usual basis for arriving at the value of the goodwill of an undertaking, the property and other assets being as a rule taken over at the valuation of an expert, but assuming that such a basis is a fair one to apply to the tramway undertaking as a whole, the number of years used as the multiplier should be arrived at after due consideration is given to the permanence and profitable character of the undertaking, and the provision made for depreciation and renewals, before arriving at the net income to which the multiplier is to be applied.

The valuer has fixed 25 years as his multiplier, but in so doing it is thought that he has not given sufficient consideration to the possibility of supersession by some other system of traction and competition by other means of conveyance.

The report continues: The valuer, in arriving at his figure of net income, for the southern system, has not in our opinion made sufficient allowance for renewals and nothing at all for contingencies such as accidents or for possible loss by the substitution of other means of traction.

If the net income had been properly ascertained, we consider that 25 times the amount of the annual net income yielding a purchaser only 4 per cent. is too high a valuation for an undertaking subject to all the risks of a tramway enterprise and the liability to make good the roads in the event of its discontinuance. In our opinion, without questioning the principle, we think that both the multiplier and the net income are too great.

The balance sheet as published is presented in a very clear and concise form, and we have no suggestion to make for its alteration, except the following :—(1) That the total capital expenditure on the horse traction system should be shown distinct from that on the electric traction system; (2) instead of showing the debt repaid out of revenue as "excess of assets and capital outlay over liabilities" it should appear as depreciation reserve account—total debt repaid to date, charged against revenue as depreciation of the assets of the undertaking. We recommend that the revenue accounts should be presented in a summarised form, with schedules giving details. The details of the power expenses do not appear in the revenue account, but in a schedule, and we think on the whole it would be preferable if the other charges against revenue account, such as traffic expenses, repairs, and general expenses, were dealt with in the same way, and then the revenue account would give a view of the net results attained by showing the gross totals of leading items of expense and revenue and the schedules would supply necessary details for those desiring to examine them.

COMPARING GERMAN AND ENGLISH WIRING RULES

MR. W. P. STEINTHAL read a Paper before the Leeds Local Section of the Institution of Electrical Engineers last Thursday, in which he compared the rules for electric installation work drawn up by the Society of German Electrical Engineers (Verband Deutscher Elektrotechniker), with those of the Institution of Electrical Engineers.

While the Institution rules "are intended neither to take the place of a detailed specification nor to instruct untrained persons," the author thinks that if an installation is erected to the regulations of the German society, no further specification could in any circumstances be required. Although the general tendencies of the two sets are similar, there are notable differences.

Current Density.—From 9 amperes to 20 amperes the current density in conductors permissible in Germany is three times or more, from 20 amperes to 200 amperes twice or more, from 200 amperes to 240 amperes one and a half times or more, and for 500 amperes 1·3 times that of the I.E.E. rules, and the author has been unable to find any limit given to the permissible drop of pressure.

[This at once renders valueless the author's opinion that the German rules can take the place of a detailed specification.—Ed. E.E.]

Insulation.—The author thinks it may be assumed that pure rubber-covered wires have been "entirely discarded" in this country except for flexibles. In Germany they are used to some extent for surface work up to 110 volts. The use of this rubber-covered wire, he says, is what is referred to in this country as "Continental wiring with flexibles," but the conductors are not flexibles in our meaning of the word, and are merely pure rubber-insulated wires as against vulcanised rubber wires. For installations up to 125 volts where the work is done on the surface the use of this rubber-covered wire, fixed on porcelain bobbins, is very common. This method of installation is cheap, and, if properly carried out, neat and perfectly sound from an electrical point of view.

The radial thickness of insulation required is appreciably smaller in the case of the German rules. This is shown in Table I.

Table I.: Radial Thickness of Insulation.

Cross-section. Sq. mm.	Mils V.D.E.	Mils I.E.E.
1·0	31	40
1·5	31	41
2·5	39	44
4·0	39	47
6·0	39	47
10·0	47	52
16·0	47	62
25·0	55	71
35·0	55	76
50·0	62	80
70·0	62	87
95·0	70	94
120·0	70	101
150·0	78	107
240·0	94	125
500·0	125	141

Flexibles.—The very exhaustive Paper read by Professor Schwartz last year to this Institution deals very fully with the subject of flexibles, and in Appendix C of that Paper will be found the German rules as they stood in 1905. The 1908 rules contain no appreciable modification. One German rule in particular relates to the supporting of a fitting by means of an additional wire, which carries no current, in addition to the actual conductor carrying the current. [The author of the present Paper omits to explain that the addition is only required in the case of counterweight pendants, and that even then an additional "cord," made up with the wire, may be used instead of a third wire.—Ed. E.E.]

Insulation Resistance.—The German requirements are put in a rather different form from that to which we are accustomed in this country. They do not base their tests according to numbers of points, but they require that the leakage current should not exceed 1 milliampere between any two fuses, and further, that a distributing board should have an insulation resistance of 1,000 ohms multiplied by the pressure of supply. In measuring the leakage current, it is specified that the minimum pressure for the testing current should be 100 volts.

The author next calls particular attention to the following points in the German rules:

The cross-section of conductors employed for making earth connections must be proportioned with due regard to the strength of the possible earth current. The smallest cross-section in electric power-rooms is to be 0·248 sq. in. (16 sq. mm.), and 0·0062 sq. in. (4 sq. mm.) elsewhere; generally for copper conductors, 0·00155 sq. in. (1 sq. mm.) for every 10 amperes may be reckoned.

Cells in battery rooms must be so arranged that the attendant cannot simultaneously touch two points between which the difference of potential exceeds 250 volts.

The nominal working current and pressure should be marked on switches. The author expresses strong approval of this rule, and also of the following: Plugs for the connection of movable conductors must be so constructed that they do not fit sockets made for a higher current strength. The normal current capacity and pressure should be marked on the socket and on the plug.

Under the heading of fuses, the author notes that the Edison screw type of fuse plug is used almost universally in Germany, where particular value is attached to non-interchangeability.

Switch lamp holders are not permitted for use with hand lamps.

The use of papier-mâché conduit with either a brass or an iron sheath appears to be very common in Germany. This type of conduit is, the author believes, sold in this country under a trade mark "Adnil." From inquiries he has made, this conduit does not appear to offer any advantage as regards price, but he adds that it is possible that there may be a saving in cost of labour with this type of conduit over the steel conduit in general use here.

Another matter to which the author calls attention is that in the German rules a layer of pure rubber between the conductor and vulcanised rubber insulation is not specified.

DISCUSSION.

Mr. R. H. Campion (Dewsbury), in opening the discussion, said he wished the Paper had been read before the last revision of the Institute Rules, as we might have benefited by the comparison. The main point of difference appeared to be the permissible current density in the conductors. The Germans allowed a considerably higher limit, resulting in less expensive work. All the Continental surface wiring which had come under his notice was for about 100 volts. He considered the English practice of painting all the bus-bars of switchboards accessible from the back with red, a better plan than merely marking the polarity on the bars. The rule requiring the marking of all switches with the nominal working current and pressure was worthy of copying, also that specifying that controllers, heating apparatus, &c., should be mounted clear of the walls. The regulations referring to the non-interchangeability of fuses were very instructive. The average Englishman was so anxious to get the current on that he would use anything handy as a fuse, from a hair-pin to a pocket-knife, with consequent risk of overload. This would be impossible with a proper system of standardised cartridge fuses.

Dr. R. Pohl (Bradford) defended the V.D.E. Rules, and considered that in this country we might with advantage permit higher current density in our cables than is the present practice. With metal filament lamps the voltage variation possible is greater than with carbon lamps. The amount might be increased from 2½ per cent. to 3½ per cent. for the same drop in candle-power; also by raising the current density it would be possible to transmit to greater distances. The German rules were enforced in practice, but it is not so with the I.E.E. rules. It is very deplorable there should be so many different sets of rules in this country, and he was strongly of the opinion that only one set should be recognised, and if it were possible, they should also be international. He supported the V.D.E. rule that fuses should not be interchangeable for different current strengths. The climate on the Continent was on the average drier than in this country, but he did not consider that an important consideration, as they had a considerable rainfall and many damp days.

Mr. S. W. Cuttriss (Leeds) said that, although there were many minor points of difference between the two sets of rules, the main points of distinction, so far as installation work is concerned, appear to be the current density, quality, and thickness of dielectric and method of installing the wires. No doubt in this country we erred on the side of low density, but it is a good fault, as it allowed a better margin for overloading, which constantly took place by the addition of more lamps, without due consideration of the capacity of the wires. While not desiring to reflect on the soundness of the V.D.E. rules referring to the insulation of conductors, he was very much in favour of keeping up the quality, even for very low voltages. An insulation test meant little or nothing in con-

Digitized by Google

sidering the life of an insulated wire. In this matter we were largely at the mercy of the manufacturers, and could do little else than trust that the higher the grade the more good rubber it contained, consequently the longer the useful life. He remarked that wood-casing appears to be entirely neglected on the continent, judging by the rules, and in this respect we had the advantage. Despite the claims of the Conduit people, wood-casing properly installed in suitable situations could not be beaten as a convenient and reliable protection for the wires. Referring to "Continental Wiring" (unprotected surface work), the revised I.E.E. rules embodied a concession in that respect, and there was little doubt that, since the advent of low voltage metal filament lamps, its adoption would extend, especially for small houses. For installations of 50 volts and under, where the risk of shock and fire is practically nil, he considered that special rules might with advantage be compiled, allowing further concessions in the matter of installation.

Mr. H. Visger (Leeds) said the German rules were generally accepted and enforced, and it would be much more satisfactory if our own rules were treated in a similar manner. At present a contractor does not know where he is with regard to rules and regulations, and in private plants they are often more or less ignored unless there is independent supervision. He was also in favour of the non-interchangeability of fuses, as sometimes under present methods too large a fuse is inserted, and fire resulted. Referring to the question of insulation, generally the grade is specified higher than necessary. The success of an installation very often depended on the way the work is executed rather than on the quality of the wire.

Mr. S. D. Jones (Batley) considered that the Germans should be given credit for knowing what they wanted. There were too many rules in this country, and still more coming. The insulation of battery stands from earth was a good thing, and had only recently been adopted here. He also spoke in favour of increasing the current density and the size of solid wires permissible.

Mr. J. T. Fawcett (Leeds) remarked that although the specified thickness of the dielectric is less than required in this country, he would like to know whether manufacturers adhered to the rule; his impression was they exceeded it. In reference to flexibles, although no mention was made of a pure rubber covering against the wire, he had found such a covering in some German flexibles. The speaker also had a tilt against the multiplicity of rules in this country, and advocated that the I.E.E. rules be made compulsory by law.
